From First Courses to the Modular Degree

A modular textbook on the arithmetic behind
"Local factors of the adjoint L-function and the ℓ-adic valuations of the modular degree"

Version of October 24, 2026

Preface

This book exists for one paper: the research note

> D. Soni, *Local factors of the adjoint L-function and the ℓ-adic valuations of the modular degree*,

a short text that uses, without pausing, elliptic curves over local fields, Galois representations and their adjoints, modular forms and Hecke algebras, Galois cohomology and Bloch-Kato Selmer groups, the commutative algebra of congruence ideals, and large computations on Cremona's tables. The book takes a reader who has none of this, but who has the background listed below, to the point where every definition and every proof of the paper, and every table that its source prints, can be read with understanding. The paper's data tables are printed in it, and the data files and scripts behind them are in the repository that its appendix names. It also serves a second reader: the specialist who has seen all of this, has forgotten the exact form of one statement, and opens one chapter to find it at the top. Throughout, "the paper" means this note, and its results are named by the labels of its source.

What the paper proves

Let E be an elliptic curve over $\mathbb{Q}$ of conductor N. By the modularity theorem there is a newform $f = f_E$ of weight 2 on $\Gamma_0(N)$ with the same L-function as E, and a nonconstant map of curves $\varphi_E\colon X_0(N) \to E$ from the modular curve $X_0(N)$ to E. Among the curves isogenous to E there is one, the $X_0(N)$-optimal curve, for which the degree of this map is smallest; the paper always takes E to be that curve and calls $\deg \varphi_E$ the modular degree. The modular degree is an integer that can be computed, curve by curve, and the tables list it; what is not understood is its prime factorisation.

The paper proves that the ℓ-adic valuation $v_\ell(\deg \varphi_E)$, for an odd prime ℓ, is determined by a Selmer group and by invariants of E at the primes of bad reduction, and is bounded below by the local invariants alone. Two local invariants enter.

- At a bad prime q, the adjoint L-function $L(\mathrm{ad}^0 f, s)$ has a local Euler factor $L_q(A_f, s)$, defined through the inertia invariants of the trace-zero adjoint $A_f = \mathrm{ad}^0 V_\ell E$. The naive adjoint L-function, the one built from the coefficients $a_n(f)$ alone, has the same factor when E has good or multiplicative reduction at q and the trivial factor 1 when the reduction is additive. The first invariant is

$$e_\ell(E, q) = v_\ell\Big(\frac{L_q(A_f, 1)^{-1}}{L_q^{\mathrm{nv}}(A_f, 1)^{-1}}\Big),$$

the ℓ-adic valuation of the Euler factor at $s = 1$ that the naive L-function omits. It is zero at multiplicative primes. At an additive prime $q \geq 5$ it is read off the Kodaira type: $v_\ell(q - \chi_{-3}(q))$ for the types II, II*, IV, IV*; $v_\ell(q - \chi_{-4}(q))$ for III, III*; $v_\ell(q^2 - 1)$ for I_n^*; and $v_\ell(q-1) + v_\ell((q+1)^2 - a_q(E')^2)$ for I_0^*, where E' is the quadratic twist of E that has good reduction at q. Here χ_{-3} and χ_{-4} are the quadratic characters of $\mathbb{Q}(\sqrt{-3})$ and $\mathbb{Q}(i)$. At $q = 2$ and $q = 3$ the factor is not determined by the Kodaira type alone; the paper shows that it has one of four shapes at every bad prime ([paper: Proposition prop:shapes]).

- At a prime q where E has potentially multiplicative reduction, that is, where $v_q(j_E) < 0$, the second invariant is $t_\ell(E, q) = v_\ell(-v_q(j_E))$, the ℓ-part of the valuation of the Tate parameter; it is 0 at every other prime.

The main theorem ([paper: Theorem thm:main]) says: if E is $X_0(N)$-optimal, ℓ is an odd prime not dividing $2N$, and the mod ℓ Galois representation $\bar{\rho}_{E,\ell}$ on $E[\ell]$ is absolutely irreducible when restricted to $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell^*}))$, where $\ell^* = (-1)^{(\ell-1)/2}\ell$, then

$$v_\ell(\deg \varphi_E) \;=\; \mathrm{length}_{\mathbb{Z}_\ell} H^1_f(\mathbb{Q}, \mathrm{ad}^0 T \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell) + \sum_{q|N} v_\ell(\mathrm{Tam}_q(\mathrm{ad}^0 T)) + \sum_{q|N} e_\ell(E, q).$$

Here $T = T_\ell E$ is the Tate module, H^1_f is the Bloch-Kato Selmer group of the adjoint, and Tam_q is the Tamagawa factor of Fontaine and Perrin-Riou. The hypothesis says that ℓ is not in the exceptional set S_f of Diamond, Flach and Guo; for $\ell \geq 5$ it only asks that $E[\ell]$ be irreducible ([paper: Proposition prop:Sf]). The Tamagawa factors are trivial at the potentially good primes ([paper: Lemma lem:tamadd]) and explicit at the potentially multiplicative ones ([paper: Lemma lem:tamfactor]): there their valuation is $v_\ell(n) + \min(v_\ell(n), v_\ell(q-1), v_\ell(c(u)))$, where $n = -v_q(j_E)$ and $v_\ell(c(u))$ is the largest $k \leq v_\ell(q-1)$ such that the reduction of the unit part u of the Tate parameter is an ℓ^k-th power in $\mathbb{F}_q^\times$; in particular it is at least $t_\ell(E, q)$. Since the Selmer length is nonnegative, the identity gives

$$v_\ell(\deg \varphi_E) \;\geq\; \sum_{q|N} e_\ell(E, q) + \sum_{q|N} t_\ell(E, q).$$

The assembly. The proof of the main theorem is not a new argument but a reading, for elliptic curves, of theorems already in the literature, and the book is organised around those theorems. They are: the theorem of Diamond, Flach and Guo identifying the length of the Σ-imprimitive adjoint Selmer group with the valuation of a congruence ideal (their Theorem 3.7); their formula for how that ideal changes with Σ (their Proposition 1.4); their exact sequence comparing the Σ-imprimitive and the Bloch-Kato Selmer groups (their Lemma 2.1), whose local terms are, by the formula of Fontaine and Perrin-Riou, the true Euler factors times the Tamagawa factors; and the observation that for the optimal curve the congruence ideal at level N is generated by $\deg \varphi_E$, by the projection formula for φ_E ([paper: Proposition prop:pullback]). The naive Euler factors at the multiplicative primes cancel, the true factors at the additive primes are the omitted ones, and the identity appears. One input of the assembly is not a published statement in the form needed: the identification of the integral structure of Diamond, Flach and Guo with the ℓ-adic cohomology of a modular curve $X_0(M)$. The paper proves it, for every prime ℓ and with no localisation ([paper: Proposition prop:integral]), and Chapter 20 gives the proof in full.

Two further statements are proved by other means. The first, proved by level lowering (Ribet, Carayol, Diamond) and quadratic twisting, says that ℓ divides the modular degree as soon as E has a prime of type IV or IV* ($q \geq 5$ or $q = 2$) or of type II or II* ($q \geq 5$), for $\ell = 3$, or an

odd prime of type I_n^* with $\ell \mid n$ ([paper: Theorem thm:qual]). The second, proved by a twisting argument and the level-raising formula of Diamond, Flach and Guo, is a quantitative version for the types I_0^* and I_n^* at the odd primes ([paper: Theorem thm:quant]); its inequality needs only the irreducibility of $E[\ell]$, so it holds also for the curves at the boundary described next, and it is an equality when $\ell \notin S_f$.

The boundary. The hypothesis on $\mathbb{Q}(\sqrt{\ell^*})$ is the hypothesis of Diamond, Flach and Guo, and the paper shows that it is sharp. For $\ell \geq 5$ it follows from the irreducibility of $E[\ell]$. For $\ell = 3$, with $E[3]$ irreducible, it fails exactly when the image of $\bar{\rho}_{E,3}$ is the normaliser of a split Cartan subgroup of $\mathrm{GL}_2(\mathbb{F}_3)$ (the image labelled 3Ns in the tables); then $\bar{\rho} \simeq \bar{\rho} \otimes \chi_{-3}$, and a correction term $h_3(E)$, the length of $H^0(\mathbb{Q}, \mathrm{ad}^0\, T(1) \otimes \mathbb{Q}_3/\mathbb{Z}_3)$, appears with the value 1 ([paper: Proposition prop:ns]). On the tables these curves violate the inequality, always by exactly one, in 31%, 23% and 18% of the cases on three ranges of conductors. The paper states a conjecture ([paper: Conjecture conj:euler]) with this correction and with a weight at the prime 3 itself when $3 \mid N$, valid also when ℓ divides N, where no theorem applies; the correction is the term that Lemma 2.1 of Diamond, Flach and Guo produces, provided a Selmer group of V^D vanishes, which is assumed and not known for these curves. A second conjecture concerns the Eisenstein case, when E has a rational ℓ-isogeny ([paper: Conjecture conj:eis]); the paper proves that its bound at $\ell = 3$ follows from its first bound ([paper: Proposition prop:no9]).

The computations. Everything was tested on Cremona's tables of elliptic curves of conductor at most 500000, with a protocol fixed in advance: a working set ($N \leq 300000$) on which the statements were found, a hold-out ($300000 < N \leq 400000$) on which they were tested once, an extension ($400000 < N \leq 500000$), and 893 curves of conductor between 500000 and four million, generated and computed independently. The Euler factors at every bad prime, including the wild primes 2 and 3, are taken from PARI. At $\ell = 3, 5, 7, 11, 13$, for the curves without complex multiplication with $E[\ell]$ irreducible that the tables determine to be optimal, the conjecture holds with no exception; at $\ell = 3$ the bound is attained for 57% of the curves with a positive bound; and a calibration argument shows that the absence of violations is far from what independence of the two sides would predict. That shows that the statement is strong, not that it is true; Chapter 22 explains the difference and which statements were tested blind.

In several places the book proves a statement in greater generality than the paper needs; where it does, the chapter says so, and the paper's statement is recovered as a special case.

Who the book is for, and the two ways to read it

The reader we have in mind has taken a first course in real analysis (sequences, series, continuity, differentiation, the Riemann integral, uniform convergence, metric spaces at an elementary level), a first course in linear algebra (vector spaces over $\mathbb{R}$ and $\mathbb{C}$, matrices, determinants, eigenvalues, diagonalisation, inner products, the Jordan form as a statement), an introduction to complex analysis (holomorphic functions, Cauchy's theorem, residues, Laurent series, Mobius transformations), an elementary course in statistics (means, variances, distributions, hypothesis tests), and has worked through Riley, Hobson and Bence, *Mathematical Methods for Physics and Engineering*: Fourier series and transforms, differential equations, special functions, tensors, finite groups and their representations, probability. Appendix A restates exactly what we assume from these courses, as a list of precise statements with references, and says where each is first used.

The reader has not seen abstract algebra beyond Riley, Hobson and Bence, nor Galois theory,

algebraic number theory, topology, algebraic geometry, homological algebra, modular forms, p-adic numbers or Galois cohomology. Every one of these is built from the beginning, with full proofs where the proofs are short enough to teach something, and with precise statements and references where they are not.

Two readings must both work, and the book is built so that they do.

Linear mode. The chapters are in dependency order. A reader with the background above can start at Chapter 1 and read to Chapter 22, in order, skipping nothing. This is a long road, and the paper is at the end of it.

Refresher mode. Every chapter opens with a card, *Core results at a glance*: a numbered list of the definitions, theorems, lemmas and constructions of the chapter, each stated precisely (not summarised), each tagged with its level of rigour, and each pointing to the place in the chapter where it is proved or discussed. A specialist who has forgotten the exact normalisation of the Fontaine-Perrin-Riou Tamagawa factor, or the exact hypotheses of the Atkin-Li twisting theorem, reads the card and stops. The cards together form a second, short book inside the first; the reading guide at the end of this preface says which card to open for which topic.

How the book is organised

The book has six Parts and two appendices. One chapter is one topic, readable on its own given the cards of the chapters before it.

Part I, Algebra. Chapter 1 builds group theory from the axioms: cosets, quotients, finite abelian groups, inverse limits and profinite groups, and the matrix groups $\mathrm{GL}_2(\mathbb{F}_q)$, with $\mathrm{GL}_2(\mathbb{F}_3)$ in full detail: the normalisers of the split and nonsplit Cartan subgroups and their orbits on the four lines of $\mathbb{F}_3^2$ are the key to the boundary of the paper's hypothesis. Chapter 2 does rings, polynomials, finite fields, cyclotomic polynomials, quadratic reciprocity, the characters χ_{-3}, χ_{-4}, χ_{q^*} and χ_S, and ℓ-adic valuations. Chapter 3 is the commutative algebra the paper leans on: modules, exact sequences, tensor products, discrete valuation rings and $\mathbb{Z}_\ell$, lengths, Fitting ideals, Pontryagin duality, perfect pairings and Gram determinants, finite free algebras with their idempotents, congruence ideals, Gorenstein rings. Chapter 4 is the representation theory of finite groups over any field, including characteristic ℓ, and over $\mathbb{Z}_\ell$: Schur, Maschke and its failure, Brauer-Nesbitt, induction and Clifford theory, the adjoint representation and its trace-zero part, $\mathrm{GL}_2(\mathbb{F}_3)$ on $\mathbb{F}_3^2$ and $\mathbb{F}_9^2$, lattices, and Dickson's list.

Part II, Number fields and local fields. Chapter 5 is Galois theory, finite and infinite, with Kummer theory, Chebotarev's theorem and the absolute Galois group $G_{\mathbb{Q}}$. Chapter 6 is algebraic number theory: rings of integers, Dedekind domains, the splitting of primes, decomposition and inertia groups, Frobenius elements, the quadratic and cyclotomic fields, the rings $\mathbb{Z}[\zeta_3]$ and $\mathbb{Z}_\ell[\zeta_3]$, class field theory over $\mathbb{Q}$, and the coefficient fields of eigenforms. Chapter 7 is the theory of $\mathbb{Q}_p$ and its extensions: Hensel's lemma, the structure of $\mathbb{Q}_p^\times$, unramified and tamely ramified extensions, the tame character, local Kummer theory, the Weil group, Weil-Deligne representations, local L-factors and conductors, and the local shapes that occur at a bad prime with their adjoints.

Part III, Curves and elliptic curves. Chapter 8 gives the language of algebraic curves and compact Riemann surfaces: divisors, Riemann-Roch, Riemann-Hurwitz, holomorphic differentials, the cohomology H^1 with its cup product, and correspondences with their adjoints. Chapter 9 is elliptic curves over fields: Weierstrass equations, the group law, isogenies, division polynomials, complex multiplication, curves over $\mathbb{C}$ and over finite fields, quadratic twists, the L-function, and

the Cremona labels. Chapter 10 is elliptic curves over $\mathbb{Q}_p$: minimal models, reduction types, Neron models and component groups, the Kodaira symbols and Tate's algorithm, the conductor and Kraus's semistability defect, the Tate curve, the effect of a quadratic twist on the reduction type (at $q = 3$ included), the wild primes 2 and 3, and how PARI and Cremona's tables record all this. Chapter 11 is the Galois representation $\rho_{E,\ell}$ and its reduction: the local behaviour at every kind of prime, the representation at ℓ, the Serre conductor, the possible images, the Eisenstein case, and the paper's Propositions prop:ns and prop:Sf and Lemma lem:h0.

Part IV, Modular forms and modular curves. Chapter 12 is modular forms and the curves $X_0(N)$ as Riemann surfaces, with the Petersson product, Sturm's bound and the Atkin-Lehner involutions. Chapter 13 is Hecke operators, newforms, oldforms and their U_p-eigenvalues, depleted forms, the perfect pairing between integral cusp forms and the Hecke algebra, the Atkin-Li twisting theorem and the transport of congruences along a twist. Chapter 14 is the arithmetic of $X_0(N)$ and $J_0(N)$: the modularity theorem, the modular parametrisation and the modular degree, the optimal curve, the Manin constant and the formula of Zagier and Watkins, the paper's Proposition prop:pullback (the congruence ideal of Diamond, Flach and Guo at level N and the modular degree), the congruence number and the theorem of Agashe, Ribet and Stein, and the Eisenstein ideal. Chapter 15 is the Galois representation of a newform, local-global compatibility, Serre's conjecture and the optimal-level theorem, level lowering and level raising, the paper's Lemmas lem:crit and lem:old, and the proof of the paper's Theorem thm:qual.

Part V, Cohomology, Selmer groups and L-functions. Chapter 16 is homological algebra and group cohomology, with the cohomology of a procyclic group and the model computation behind the paper's Lemma lem:tamfactor. Chapter 17 is Galois cohomology, local and global: Kummer theory, Tate local duality, unramified cohomology, the Kummer class of the Tate parameter, Selmer structures, Poitou-Tate and the Greenberg-Wiles formula. Chapter 18 is the Bloch-Kato Selmer group, the Fontaine-Perrin-Riou Tamagawa factor at every bad prime (the paper's Lemmas lem:fpr, lem:tamfactor and lem:tamadd and Corollary cor:explicit), and the Selmer half of the main theorem. Chapter 19 is L-functions: Euler products, the local factors of the adjoint and of the symmetric square, the naive versus the true adjoint L-function, the Rankin-Selberg method and the Petersson norm, the paper's Lemma lem:euler and its Proposition prop:shapes at every bad prime, and what PARI computes.

Part VI, Congruences, the modular degree and the paper. Chapter 20 is the theory of congruence ideals: Hecke algebras and their localisations, Wiles's numerical criterion and the paper's Lemma lem:ddt417, the theorems of Diamond, Flach and Guo, the comparison of their integral structure with the cohomology of the curves $X_0(M)$ (the paper's Proposition prop:integral), the Taylor-Wiles method in outline, the assembly of the paper's main theorem as an identity, the twist monotonicity theorem, and the proof of the paper's Theorem thm:quant with Step 1 as an equality. Chapter 21 is a guided reading of the paper, section by section in the paper's order: each result stated, each ingredient located in the book and each compressed step expanded; then a map of the paper (dependencies, hypotheses, imported statements) and worked verifications on curves. Chapter 22 is PARI/GP from zero, Cremona's tables and the `ecdata` files, the paper's function `rule(E, l, iii)` explained line by line, the paper's protocol and its statistics with the calibration argument, and the reproduction of the paper's tables on the curves of conductor below 10,000.

Appendices. Appendix A is the list of what we assume from the reader's first courses. Appendix B states the book-wide conventions and gives the index of every symbol of the paper and of the book, with the chapter where it is defined, and of the letters with several meanings.

The dependency graph

The table lists, for each chapter, the earlier chapters that it uses directly; it also uses, through them, whatever they use. Everything else a chapter needs is proved inside it or is in Appendix A. No chapter uses a later one in a proof: where a chapter mentions a later result, in a remark or an example, it says so.

Chapter	uses directly
1. Groups and matrix groups over finite fields	nothing
2. Rings, fields, polynomials and characters	1
3. Modules and commutative algebra	1, 2
4. Representations of finite groups	1, 2, 3
5. Galois theory	1 to 4
6. Algebraic number theory	1 to 5
7. Local fields	1 to 6
8. Curves and Riemann surfaces	1 to 6, A
9. Elliptic curves over fields	1, 2, 4, 5, 6, 8
10. Reduction, Kodaira types, Tate curves	7, 9
11. Galois representations of elliptic curves	1, 4 to 7, 9, 10
12. Modular forms and modular curves	1 to 4, 8, 9
13. Hecke operators, newforms and twists	2, 3, 6, 12
14. Modular curves over $\mathbb{Q}$, the modular degree	3, 8, 9, 12, 13
15. Galois representations of modular forms	3, 4, 7, 11, 13, 14
16. Group cohomology	1, 3, 7, 11
17. Galois cohomology, Selmer groups	3, 5 to 7, 9 to 11, 16
18. Bloch-Kato Selmer groups, Tamagawa factors	3, 7, 11, 16, 17
19. L-functions	7, 10, 11, 13, 14, 18
20. Congruence ideals, Diamond-Flach-Guo	3, 13 to 15, 18, 19
21. Reading the paper	everything before it
22. Computation, data and protocol	9 to 11, 14, 19, 21, A

In words: there are three algebraic strands (groups to representations to Galois representations; rings to modules to cohomology to Galois cohomology to Bloch-Kato; rings to Galois theory to number fields to local fields to reduction), one geometric strand (curves to elliptic curves to reduction), and one modular strand (modular forms to Hecke operators to the modular degree to the Galois representations of newforms). They meet in Chapter 19 and Chapter 20, and everything meets in Chapter 21.

How to read a chapter

Every chapter has the same shape.

1. *Core results at a glance.* The card: the numbered definitions, theorems, lemmas, propositions and constructions of the chapter, stated in full, each tagged with its level of rigour (see below), and each pointing to the numbered environment in the chapter where it lives. The card is complete: every numbered theorem, proposition, lemma, corollary and definition of the chapter is on it.

2. *Where the paper uses this chapter.* A list of the paper's lemmas, theorems, remarks, definitions and sections that depend on the chapter, and which results of the chapter they

use. The paper's results are named by the labels of the paper's own source, so that reader and paper agree on names: the paper's main theorem is [paper: Theorem thm:main], its computation of the Tamagawa factor is [paper: Lemma lem:tamfactor], its description of the boundary is [paper: Proposition prop:ns], and so on.

3. *The numbered sections.* Each section opens with one paragraph saying what it is for and where in the paper it is used. Inside the text, a box headed *In the paper* marks the exact place where a result of the chapter enters the paper, so that a reader going line by line through the paper can find the way back.

4. *Exercises.* Between eight and twenty, graded from routine to hard, with answers or hints. Some of them read "check the paper's claim that ..."; these are the ones to do.

5. *Notes and references.* Where to read more, which sources the chapter followed, which theorem numbers it cited, and which of them were checked against the source.

Chapters refer to one another only by chapter number, never by the number of a theorem in another chapter, so that each chapter stands on its own. The running examples are the curves of the paper, in Cremona's labels: `11a1`, `20a1`, `121a1`, `121c`, `121d`, `539c1`, `980i1`, `726a1` and `99A1`. They recur wherever a chapter's topic allows, and Chapter 22 shows how to reproduce every number quoted about them.

Levels of rigour

Every result on a card, and every numbered theorem in the text, carries a tag.

(proved here) The proof is in the book, complete. This is the status of most results of Parts I to III and of the commutative algebra of Part VI.

(proved here, given X) The proof is complete, except that it uses the named input X, which is proved in another chapter, or is stated with a reference, or (in a few places, each said) is only sketched. This is the status of most of the paper's own lemmas and propositions: the paper's proofs are written for experts, and the book proves each, expanding every compressed step, given the statements that the paper imports.

(proof sketched here) The statement is precise, with all its hypotheses. The shape of the proof is explained, in a paragraph or a page, enough to see why the statement is true and what it costs; a reference with a theorem number carries the rest. A sketch is always labelled as a sketch and never presented as a proof.

(stated; reference) The statement is precise, with all its hypotheses, and no proof is given; the reference says where one is. This is the status of the deep theorems: modularity, Serre's conjecture, the level-lowering theorems, the theorems of Diamond, Flach and Guo, the formula of Fontaine and Perrin-Riou, Tate local duality, Poitou-Tate.

Definitions and conventions are tagged as such, and a statement established by a computation printed in the book is tagged *(proved here, by computation)*, with its range. The rule that governs the choice is that a card entry that is wrong is worse than one that is missing.

How the book was checked

Every chapter was reviewed adversarially after it was written, by a review that looked for false statements, missing hypotheses, gaps in proofs and tags that claim more than the text proves, and the problems found were fixed. Every number the book prints was recomputed with PARI/GP 2.17.2 and Cremona's tables (the `ecdata` files at commit `25cec5e`, conductors below 10,000), and is printed with the range it covers; numbers that the paper reports for its larger ranges are quoted as the paper's and marked as such, since they cannot be rerun from those data. The cited literature was checked against the sources where the sources were available. A statement that was not checked against its source, or a theorem number that was not verified, is marked as such where it appears.

Conventions

Notation follows the paper. The paper's symbols are the book's: $V = V_\ell E$, $T = T_\ell E$, $\rho = \rho_{E,\ell}$, $\bar\rho$, $A_f = \mathrm{ad}^0 V$ (the trace-zero adjoint, always), δ_p, $L_p(A_f, s)$ and $L_p^{\mathrm{nv}}(A_f, s)$, $P_q(X)$, $e_\ell(E,q)$, $t_\ell(E,q)$, n_q, q_E and its unit part u, Tam_p, Fitt, H^1_f, H^1_Σ, W, T^D, V^D, W^D, S_f, $\eta^\Sigma_{f,\lambda}$, $M_{f,\lambda}$, $\hat\delta_!$, ϕ_f, I, J, r_E, $\deg\varphi_E$, Φ_q^{geom}, c_q, $w_\ell(E,q)$, $w_3(E)$, $h_\ell(E)$, χ_{-3}, χ_{-4}, χ_{q^*}, χ_S, q^*, ℓ^*, $E^{(q)}$, E_S, $N_s(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$, 3Ns. Where the paper is ambiguous or uses one letter for two things, Appendix B fixes the book's reading; it lists every symbol with the chapter where it is defined.

Valuations and lengths. v_ℓ is the ℓ-adic valuation normalised by $v_\ell(\ell) = 1$, extended to $\mathbb{Q}$ and to the fraction field of a discrete valuation ring; "length" means $\mathbb{Z}_\ell$-length (or $\mathcal{O}$-length when a ring $\mathcal{O}$ is named).

Frobenius. Arithmetic and geometric Frobenius are inverse to each other, and the literature uses both. In the book, as in the paper, Frob_p is an arithmetic Frobenius and the local L-factors use the geometric one: $L_p(M,s) = \det(1 - \mathrm{Frob}_p^{-1}\, p^{-s} \mid M^{I_p})^{-1}$. A good prime has Frobenius eigenvalues α/β, 1, β/α on $\mathrm{ad}^0 V$, and $L_p(\mathrm{Sym}^2 f, s) = L_p(A_f, s-1)$ relates the symmetric square to the adjoint.

Names. Double and triple names are hyphenated: Bloch-Kato, Atkin-Lehner, Atkin-Li, Brauer-Nesbitt, Diamond-Flach-Guo, Fontaine-Perrin-Riou, Taylor-Wiles, Riemann-Roch. A result is named by its authors on first appearance (the theorem of Agashe, Ribet and Stein) and by the book's label afterwards.

Kodaira symbols and labels. The Kodaira symbols are I_0, I_n, II, III, IV, I_0^*, I_n^*, IV*, III*, II*; PARI's integer codes for them are explained in Chapter 10 and Chapter 22. Cremona labels are set in typewriter type, `121a1`; the paper's class labels `121c` and `121d` and the older capitalised label `99A1` are kept as the paper writes them.

Typography. Sentences are short. There are no dashes in the book: a parenthesis, a colon or a semicolon does the work. Number ranges are written "pages 663 to 727".

A reading guide for the expert

The specialist who wants one statement should go straight to the card of the chapter that holds it. A dozen of the most likely requests:

- To recall the Tamagawa factor of Fontaine and Perrin-Riou,

$$\mathrm{Tam}_p(M) = \mathrm{Fitt}_{\mathbb{Z}_\ell}\big((H^1(I_p, M)_{\mathrm{tors}})^{G_{\mathbb{Q}_p}}\big),$$

its relation to the torsion of $H^1(\mathbb{Q}_p, T^D)$ and the Euler factor, its value at every bad prime, the exceptional set S_f, and the exact sequence of Lemma 2.1 of Diamond, Flach and Guo, open Chapter 18.

- For the Atkin-Li twisting theorem, the eigenvalues of U_p on oldforms with the stabilisations and the depleted forms, the transport of congruences along a twist, and the perfect pairing between the integral cusp forms $S_2(\Gamma_0(N);\mathbb{Z})$ and the Hecke algebra $\mathbb{T}$, open Chapter 13.

- For Tate's algorithm, the Kodaira types with their geometric component groups, Kraus's semistability defect $12/\gcd(v_q(\Delta), 12)$, and the exchange of types under the twist by $\mathbb{Q}(\sqrt{q^*})$, at $q = 3$ included, open Chapter 10.

- For Theorem 3.7, Proposition 1.4, Lemma 2.1 and Theorem 2.7 of Diamond, Flach and Guo as read for weight 2, Wiles's numerical criterion in the form of Lemma 4.17 of Darmon, Diamond and Taylor, the lattice $M_{f,\lambda}$ and the pairing $\hat{\delta}_!$, the assembly of the main theorem, and the proof of Theorem thm:quant, open Chapter 20.

- For the theorem of Agashe, Ribet and Stein, the congruence number, the Manin constant, the formula of Zagier and Watkins for the modular degree, the projection formula behind Proposition prop:pullback, multiplicity one, and the comparison of Ribet and Takahashi, open Chapter 14.

- For the optimal-level theorem, Ribet's level lowering and level raising, local-global compatibility at a multiplicative prime, the description of $\bar{\rho}$ at ℓ, and the congruence criterion and oldform lemma of the paper, open Chapter 15.

- For $\mathrm{GL}_2(\mathbb{F}_3)$, its subgroups $N_s(\mathbb{F}_3)$ and $N_{ns}(\mathbb{F}_3)$, their determinant-one subgroups and their orbits on the four lines of $\mathbb{F}_3^2$, open Chapter 1; for the images of $\bar{\rho}_{E,3}$, the Sutherland labels, and the paper's Propositions prop:ns and prop:Sf and Lemma lem:h0, open Chapter 11.

- For Brauer-Nesbitt, Clifford theory for an index-two subgroup, induced representations and Frobenius reciprocity, and the identity $\mathrm{ad}^0\,\rho = \mathrm{Sym}^2\,\rho \otimes \det\rho^{-1}$, open Chapter 4.

- For the tame character, the relation $\mathrm{Frob}\; t\; \mathrm{Frob}^{-1} = t^q$, the Kummer class of a uniformiser and its restriction to inertia, Weil-Deligne representations, and the conductor of a ramified twist of Steinberg, open Chapter 7.

- For inflation-restriction, $H^1(\langle t\rangle, M) = M/(t-1)M$ for a procyclic group, and the conjugation action of G/I on $H^1(I, M)$, open Chapter 16; for Tate local duality, the Greenberg-Wiles formula and the comparison of Selmer groups for two sets of local conditions, open Chapter 17.

- For the table of Euler factors of the adjoint at the bad primes, the four shapes of the factor at every bad prime, the naive versus the true adjoint L-function, the Rankin-Selberg formula for the Petersson norm, and what PARI's `lfunsympow` returns, open Chapter 19.

- For Fitting ideals, lengths, Pontryagin duality, saturated sublattices and Gram determinants, open Chapter 3; for Chebotarev's theorem and $\mathbb{Q}(\sqrt{\ell^*})$ as the quadratic subfield of $\mathbb{Q}(\zeta_\ell)$, open Chapter 5; for $\mathbb{Z}_3[\zeta_3]$ as a discrete valuation ring and the Frobenius of $\mathbb{Q}(\sqrt{-3})$, open Chapter 6.

- For a guided reading of the paper section by section, with each result traced to its ingredients, and the table "hypothesis, where it is used, what fails without it", open Chapter 21; for the data protocol, the calibration argument and the PARI function `rule(E, l, iii)`, open Chapter 22.

Acknowledgement

The book was planned and directed by the author of the note, D. Soni. It was written by an AI system, Claude, made by Anthropic: the drafting of every chapter, the adversarial reviews, the fixes and the computations were all done by it. The mathematics has been checked by the reviews and the computations described above, but it has not yet been read line by line by a human expert. Readers should treat it accordingly, and are asked to report the errors they find.

A reviewer's route

These pages are for a specialist who has been asked to referee the paper and wants the shortest path through it: the statement, the chain of the proof with the place where each link is proved, the joints to check in order, what is imported, and what the numbers rest on. Chapter 21 reads the paper section by section; Chapter 20 holds the proofs of Section 4. Paper labels are quoted as text (Proposition prop:integral), as in the rest of the book.

1. The statement

Hypotheses. $E/\mathbb{Q}$ is the $X_0(N)$-optimal curve of its isogeny class, $f = f_E$; ℓ is an odd prime with $\ell \nmid 2N$, and $\bar{\rho}_{E,\ell}$ is absolutely irreducible on $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell^*}))$, $\ell^* = (-1)^{(\ell-1)/2}\ell$; that is, $\ell \notin S_f$ in the notation of Diamond, Flach and Guo. For $\ell \nmid 2N$ this says: $E[\ell]$ is irreducible and, if $\ell = 3$, the mod 3 image is not $N_s(\mathbb{F}_3)$ (Proposition prop:Sf). With $T = T_\ell E$, Theorem thm:main states

$$v_\ell(\deg \varphi_E) = \mathrm{length}_{\mathbb{Z}_\ell} H^1_f(\mathbb{Q}, \mathrm{ad}^0 T \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell) + \sum_{q|N} v_\ell(\mathrm{Tam}_q(\mathrm{ad}^0 T)) + \sum_{q|N} e_\ell(E,q), \tag{eq:identity}$$

$$v_\ell(\deg \varphi_E) \;\geq\; \sum_{q|N} e_\ell(E,q) + \sum_{q|N} t_\ell(E,q), \tag{eq:thm}$$

where $e_\ell(E,q) = v_\ell(P_q(q^{-2})/(1-a_q(E)^2q^{-2}))$ is the valuation of the Euler factor of $L(\mathrm{ad}^0 f, s)$ at $s=1$ that the naive adjoint L-function omits (zero unless q is additive), and $t_\ell(E,q) = v_\ell(-v_q(j_E))$ when $v_q(j_E) < 0$, and 0 otherwise (Definition def:terms). The second line follows from the first because the Selmer length is nonnegative and $v_\ell(\mathrm{Tam}_q(\mathrm{ad}^0 T)) \geq t_\ell(E,q)$ (Lemma lem:tamfactor). Conjecture conj:euler, which extends the inequality to $\ell \mid N$ and to the image 3Ns, is not part of the theorem.

2. The chain of the proof

The paper's proof of Theorem thm:main is the table at the start of its Section 4.3; the rows below follow it. "Paper" means proved in the paper, "book" that the book gives a complete proof (expanding the paper's), "imported" that the statement is cited.

step	paper label	in the book	status
$H^1(X_0(N),\mathbb{Z}_\ell)$ is the integral structure of DFG, Hecke equivariantly, U_p included	prop:integral	Chapter 20	paper; book (full proof)
$v_\lambda(\eta^{\emptyset}_{f,\lambda}) = v_\ell(\deg\varphi_E)$ (projection formula)	prop:pullback, lem:hecke	Chapters 14 and 20	paper; book; uses [3, Theorem 2.2] for r_E
$\eta^{\Sigma} = \eta^{\emptyset}\prod_{p\in\Sigma} L_p^{\mathrm{nv}}(A_f,1)^{-1}$	thm:dfg14	Chapter 20	imported, [49, Proposition 1.4(c)]
$\ell \notin S_f$ read for elliptic curves; $H^0(\mathbb{Q},W^D)$ of length $h_\ell(E)$	prop:Sf, lem:h0, prop:ns	Chapters 4 and 11	paper; book
$v_\lambda(\eta^{\Sigma}) =$ length $H^1_\Sigma(\mathbb{Q},W)$	thm:dfg37	Chapter 20 (outline)	imported, [49, Theorem 3.7]
$H^0(\mathbb{Q},V^D) = H^1_f(\mathbb{Q},V^D) = 0$	thm:dfg27	Chapters 18 and 20	imported, [49, Theorem 2.7]
$H^1_\Sigma(\mathbb{Q},W)$ against $H^1_f(\mathbb{Q},W)$	lem:dfg21	Chapters 17 and 18	imported, [49, Lemma 2.1]; the paragraph after it paper, book
Fitt $H^1_f(\mathbb{Q}_p,T^D) = L_p(A_f,1)^{-1}\,\mathrm{Tam}_p(A)$	lem:fpr	Chapters 18 and 19	imported, [69, I.4.2.2], [49, (57)]; first identity also proved in book
values of e_ℓ; shapes of P_q	def:terms, lem:euler, prop:shapes	Chapters 10, 11 and 19	paper; book
$\mathrm{Tam}_q(\mathrm{ad}^0\,T)$ at the bad primes	lem:tamfactor, lem:tamadd	Chapters 17 and 18	paper; book
the assembly	proof of thm:main, cor:explicit	Chapter 20	paper; book

3. The delicate joints, in order

(a) *Proposition prop:integral.* This is the one input that the paper says is "not a published statement in the form we need"; the paper proves it, and adds that "it holds integrally, with no localisation." The proof identifies DFG's Betti lattice $M(M,1)_{!,B}$, defined as invariants of the cohomology of a modular curve of full level, with $H^1(X_0(M),\mathbb{Z})$: compactly supported Hochschild-Serre and the equivariant Leray sequence of the finite quotient map (Step 1), the image of $H^1_c \to H^1$ (Step 2), Hecke operators checked over $\mathbb{C}$ (Step 3), base change to $\mathbb{Z}_\ell$ (Step 4). To check: the reading of DFG's Sections 1.2 and 1.4.1 (Lemma 1.1, Proposition 1.3 for the Hecke action with U_p, display (5)), and the paragraph after the proposition, where the pairing $\hat{\delta}_!$ is $\frac{u}{2}$ times the cup product composed with w_M, u an ℓ-adic unit, by the statement before DFG's Lemma 1.2. Only the unit matters for odd ℓ; the exact constant is not proved. Chapter 20 gives the full proof; DFG's sections are cited there by section, as the paper cites them.

(b) *The DFG hypothesis chain.* Theorem thm:dfg37 needs $\ell \notin S_f$ and Σ the set of primes dividing N (minimal ramification outside Σ). Proposition 1.4(c) needs $\ell \notin \Sigma$ and $\bar{\rho}$ irreducible; the paper shows by `11a` at $\ell = 3$ that $\ell \notin \Sigma$ cannot be dropped. Lemma 2.1 needs $H^0(\mathbb{Q},V^D) = H^1_f(\mathbb{Q},V^D) = 0$: the first is automatic, as $H^0(\mathbb{Q}_p,V^D) = 0$ for $p \in \Sigma$; the second is Theorem 2.7; and its local terms are the torsion of $H^1(\mathbb{Q}_p,T^D)$ because $p \neq \ell$. The last term $H^0(\mathbb{Q},W^D)^*$ of the sequence is dropped by Lemma lem:h0, which gives length $h_\ell(E) = 0$ exactly when $\ell \notin S_f$. A referee should confirm that the four DFG statements are used in the published form and numbering (Chapter 21 lists which were compared with the

published text).

(c) *The local terms at $q = 2, 3$.* In (eq:identity) the terms at 2 and 3 are those of Definition def:terms with PARI's Euler factor; the paper states that `lfunsympow(E,2)` "returns these factors at every prime, including 2 and 3". The identity needs only the definition; Proposition prop:shapes (four shapes of P_q at every bad prime, proved from the image of inertia) makes them explicit, and Remark rem:wild gives the examples `336f1`, `1232l1`, `592c1`. The file `final/pipeline/samples/wild_euler_q23.csv` (with its `README.md` and log) records P_q, $P_q(q^{-2})$ and e_ℓ for 3,305 rows at $q = 2, 3$ (2,905 curves: those named in the paper and the optimal non-CM curves with $N < 2{,}000$ and $4 \mid N$ or $9 \mid N$), each matched to one of the four shapes, with no mismatch.

(d) *The image* 3Ns *and h_3.* Theorem thm:main excludes these curves ($3 \in S_f$). The paper's "Status of the correction" separates three things. Proved: $h_\ell(E) \le 1$, with equality exactly when $\ell = 3$ and the mod 3 image is $N_s(\mathbb{F}_3)$ (Lemma lem:h0, Proposition prop:ns). Conditional: that the correction is the term $-h_\ell(E)$ that Lemma 2.1 produces assumes $H^1_f(\mathbb{Q}, V^D) = 0$, "which is not known for these curves", and that $v_\lambda(\eta^{\Sigma}_{f,\lambda})$ is still the Selmer length (Remark rem:ns). Empirical: the weights w_3 at $q = \ell = 3$ and the shortfall pattern, a failure of (eq:thm) by exactly one on 364, 68 and 43 curves of the three table ranges, all with image 3Ns (Chapters 11 and 18).

(e) *Theorem thm:quant, Step 2.* The proof is a chain of equalities with one inequality: Lemma lem:ddt417 (the inequality half of [38, Lemma 4.17], proved in the paper) applied to $H^1(X_0(N), \mathbb{Z}_\ell)_{\mathfrak{m}}$ and the depleted form g^S of the twist, giving $v_\ell(\eta^{\mathrm{Hecke}}(g^S)) \ge v_\lambda(\eta^S_{g,\lambda})$; in the paper's words, "the only inequality is Step 2". To check: that $L[\wp]$ is the lattice $M_{g^S,\lambda}$ (Proposition prop:integral at level N), that the pairing is perfect on the $\mathfrak{m}$-component ($e_{\mathfrak{m}}$ self-adjoint), and that freeness is not used. The inequality needs only $E[\ell]$ irreducible and $\ell \nmid 2N$; the equality uses Theorem thm:main for E and E'_S (Chapter 20).

4. Imported results

As the paper cites them, for Theorem thm:main and Theorem thm:quant: [49, Proposition 1.4(c)]; [49, Theorem 3.7] (the form given as Theorem 0.2 there); [49, Theorem 2.7]; [49, Lemma 2.1], with S_f from [49, (31)]; [69, I.4.2.2], as recalled in the proof of [49, Theorem 2.15], with $\mathrm{Tam}_p(T^D) = \mathrm{Tam}_p(A)$ from [49, (57)]; for Proposition prop:integral and the pairing, [49, §§1.2, 1.4], [49, Lemma 1.1], [49, (5), Proposition 1.3] and [49, §1.5.2, before Lemma 1.2]; [3, Theorem 2.2] ($\deg \varphi_E \mid r_E$, with equal p-parts for $p^2 \nmid N$); [38, Lemma 4.17] (its inequality half is reproved); [171, §1] (inertia at ℓ, in Proposition prop:Sf); [179, §2] and [107] (inertia images at additive primes); Tate's algorithm [193], [184, IV.9]; and PARI's `lfunsympow` [148] for the factors at 2 and 3. The status of each citation (compared with the published text, or as cited) is the last table of Chapter 21.

5. The computations

No computation enters the proof of Theorem thm:main or Theorem thm:quant. The data concern Conjectures conj:euler and conj:eis, the sharpness of the hypothesis, and checks of the local lemmas. They rest on three kinds of evidence.

- *Large ranges* (conductor up to 500000, and the 893 curves outside the tables): computed by the scripts in `final/pipeline`. The book did not rerun them. It compared the printed tables with the committed result files (`scripts/selftest.py`, output in `results/selftest.log`; `MANIFEST.sha256` fixes every file), which is a consistency check, not a reproduction; the four twisted rows of Table tab:isolated could not be compared, their source files not being committed. The full rerun from the pinned data is `scripts/repro_run.sh` followed by `scripts/reproduce_tables.sh`, described in the pipeline's `README.md`, which also describes the logs of the earlier clean-clone runs; a referee should read those logs before relying on the appendix's sentence on the clean clone.
- *Conductor below* 10,000 (38,042 optimal curves): recomputed for the book with PARI/GP 2.17.2 from the same pinned commit, including Table tab:excess (Chapter 18), the check of Lemma lem:euler against PARI's factors, and the counts of Sections sec:tam, sec:anomaly and sec:wild that fall in this range (Chapter 22). These runs were made with the paper in hand: they are checks, not blind tests.
- *Single curves*: the worked verifications of Chapter 21 and the function `rule` of the paper's appendix (`scripts/euler_rule.gp`).

Which ranges were used to formulate each statement and which to test it is set out, statement by statement, in the protocol remarks of Chapter 22, with the two qualifications stated there. Each computational claim of the paper, with the evidence behind it, is listed in the claim ledger in `final/claims/`.

6. What has not been checked

The paper and this book were produced with an AI system under the author's direction, and neither has yet been read line by line by a human expert; the paper's statement on the use of an AI system and the acknowledgement in the preface say so.

Preface iii

A reviewer's route xiii

I Algebra 1

1 Groups, group actions and matrix groups over finite fields 3
1.1 Groups, subgroups, cosets, quotients and cyclic groups . . . 9
1.2 Products and the small groups . . . 13
1.3 Group actions, orbit-stabiliser, p-groups, Sylow theorems . . . 18
1.4 Finite abelian groups . . . 22
1.5 Matrix groups over a field . . . 24
1.6 The group $\mathrm{GL}_2(\mathbb{F}_3)$ in full, and $\mathrm{GL}_2(\mathbb{F}_5)$, $\mathrm{GL}_2(\mathbb{F}_7)$ . . . 33
1.7 Inverse limits and profinite groups . . . 41
1.8 Exercises . . . 45
1.9 Notes and references . . . 47

2 Rings, fields, polynomials and characters 49
2.1 Rings, ideals, quotients and products . . . 55
2.2 Prime and maximal ideals, fractions, $\mathbb{Z}_{(p)}$ . . . 61
2.3 Euclidean domains, PIDs, UFDs . . . 64
2.4 Polynomial rings and irreducibility . . . 67
2.5 The ring $\mathbb{Z}/n\mathbb{Z}$, units and primitive roots . . . 71
2.6 Finite fields . . . 74
2.7 Powers in $\mathbb{F}_q^\times$ . . . 77
2.8 Roots of unity and cyclotomic polynomials . . . 79
2.9 Quadratic residues and quadratic reciprocity . . . 82
2.10 Dirichlet characters and Gauss sums . . . 86
2.11 Valuations and the paper's local terms . . . 91
2.12 Exercises . . . 95
2.13 Notes and references . . . 97

3 Modules and commutative algebra 99
3.1 Modules, submodules, quotients and homomorphisms . . . 106
3.2 Exact sequences; free and projective modules . . . 109
3.3 Hom and tensor product; flatness . . . 113

3.4 Noetherian rings, Nakayama, localisation . . . 116
3.5 Modules over a principal ideal domain . . . 120
3.6 Discrete valuation rings and $\mathbb{Z}_\ell$ . . . 126
3.7 Length, annihilators and Fitting ideals . . . 130
3.8 Pontryagin duality . . . 135
3.9 Pairings . . . 139
3.10 Finite free algebras and generalised eigenspaces . . . 144
3.11 Congruence ideals and Gorenstein algebras . . . 151
3.12 Exercises . . . 156
3.13 Notes and references . . . 158

4 Representations of finite groups and the mod ℓ world 161
4.1 Representations over a field . . . 168
4.2 Irreducibility, Schur's lemma, absolute irreducibility . . . 172
4.3 Semisimplicity, Maschke's theorem, Jordan-Hölder . . . 174
4.4 Characters in characteristic zero . . . 179
4.5 The theorem of Brauer and Nesbitt . . . 181
4.6 Restriction, induction, Mackey and Clifford . . . 183
4.7 Twisting, the adjoint and the trace form . . . 188
4.8 $\mathrm{GL}_2(\mathbb{F}_3)$ and its subgroups on $\mathbb{F}_3^2$ and $\mathbb{F}_9^2$ . . . 193
4.9 Unipotent elements and cyclic groups of order 2, 3, 4, 6 . . . 197
4.10 Representations over $\mathbb{Z}_\ell$: lattices, reduction, homothety . . . 200
4.11 The mod ℓ world: a foretaste, and Dickson's list . . . 204
4.12 Exercises . . . 205
4.13 Notes and references . . . 208

II Number fields and local fields 211

5 Galois theory, finite and infinite 213
5.1 Field extensions and algebraic elements . . . 219
5.2 Splitting fields, normality, separability . . . 222
5.3 Galois extensions and the fundamental theorem . . . 226
5.4 Finite fields, quadratic and cyclotomic extensions . . . 229
5.5 Hilbert 90, Kummer theory, Artin-Schreier . . . 234
5.6 The Galois group of a polynomial . . . 240
5.7 Infinite Galois theory, $G_{\mathbb{Q}}$, the cyclotomic character . . . 246
5.8 Continuous representations . . . 251
5.9 Frobenius elements and the Chebotarev density theorem . . . 257
5.10 Exercises . . . 261
5.11 Notes and references . . . 262

6 Algebraic number theory 265
6.1 Number fields and their rings of integers . . . 271
6.2 Dedekind domains, ideals, norms and class groups . . . 274
6.3 Splitting of primes, ramification and Frobenius . . . 279
6.4 Quadratic fields, $\mathbb{Z}[i]$, $\mathbb{Z}[\zeta_3]$ and the rings $\mathbb{Z}_\ell[\zeta_3]$ . . . 287

6.5 Cyclotomic fields and class field theory over $\mathbb{Q}$ . . . 294
6.6 Densities, Chebotarev, complex multiplication . . . 299
6.7 Coefficient fields and primes above ℓ . . . 303
6.8 Exercises . . . 305
6.9 Notes and references . . . 307

7 Local fields **309**
7.1 Absolute values, completions, $\mathbb{Q}_p$ and $\mathbb{Z}_p$ . . . 315
7.1.1 Absolute values . . . 316
7.1.2 Completions . . . 318
7.1.3 The field $\mathbb{Q}_p$ . . . 319
7.2 Hensel's lemma; units, roots of unity and powers . . . 320
7.2.1 Hensel's lemma . . . 320
7.2.2 Teichmüller lifts and the structure of the units . . . 323
7.2.3 Powers . . . 324
7.3 Finite extensions of $\mathbb{Q}_p$ . . . 326
7.3.1 Completions of number fields . . . 329
7.4 Unramified extensions, $\mathbb{Q}_p^{\mathrm{ur}}$ and Frobenius . . . 331
7.5 Ramification groups, inertia and the tame quotient . . . 334
7.5.1 Ramification groups of a finite Galois extension . . . 334
7.5.2 The inertia group of G_K and the tame quotient . . . 336
7.6 Kummer theory over local fields; quadratic characters . . . 341
7.6.1 Quadratic extensions and quadratic characters . . . 343
7.7 The Weil group and Weil-Deligne representations . . . 345
7.8 Inertia invariants, local L-factors and conductors . . . 350
7.8.1 Swan and Artin conductors . . . 351
7.9 The local shapes and their adjoints . . . 353
7.10 Exercises . . . 357
7.11 Notes and references . . . 360

III Curves and elliptic curves **361**

8 Algebraic curves, function fields and Riemann surfaces **363**
8.1 Affine and projective varieties . . . 369
8.2 Plane curves and smoothness . . . 372
8.3 Function fields, points over extensions, the Galois action . . . 375
8.4 Divisors, differentials, the Picard group . . . 377
8.5 Riemann-Roch and its consequences . . . 379
8.6 Morphisms and their degree; the Frobenius morphism . . . 384
8.7 Ramification and the Riemann-Hurwitz formula . . . 388
8.8 Compact Riemann surfaces and complex curves . . . 390
8.9 Holomorphic differentials, residues, periods . . . 393
8.10 H_1, H^1 and the cup product . . . 395
8.11 The Jacobian; torsion and Tate modules . . . 400
8.12 Correspondences, their actions, and adjoints . . . 407
8.13 Exercises . . . 410

8.14 Notes and references . . . 413

9 Elliptic curves over fields 415
9.1 Weierstrass equations and their invariants . . . 421
9.2 The group law . . . 428
9.3 Isogenies . . . 432
9.4 Division polynomials . . . 436
9.5 The Weil pairing, Tate modules, Galois representations . . . 439
9.6 Endomorphisms and complex multiplication . . . 444
9.7 Elliptic curves over the complex numbers . . . 446
9.8 Elliptic curves over finite fields . . . 451
9.9 Curves over the rationals: torsion and isogenies . . . 455
9.10 Quadratic twists . . . 460
9.11 The L-function . . . 463
9.12 Labels and the running examples . . . 465
9.13 Exercises . . . 466
9.14 Notes and references . . . 468

10 Elliptic curves over local fields: reduction, Kodaira types, Tate curves 471
10.1 Integral and minimal Weierstrass models . . . 476
10.2 Reduction modulo the uniformiser . . . 480
10.3 Potentially good and potentially multiplicative reduction . . . 484
10.4 Néron models and component groups . . . 486
10.5 Kodaira symbols and Tate's algorithm . . . 489
10.6 The conductor and the semistability defect . . . 496
10.7 The Tate curve . . . 502
10.8 Quadratic twists and reduction . . . 507
10.9 The wild primes 2 and 3 . . . 511
10.10 Cremona's tables and PARI . . . 514
10.11 Exercises . . . 515
10.12 Notes and references . . . 517

11 Galois representations of elliptic curves 519
11.1 The representations $\rho_{E,\ell}$ and $\bar{\rho}_{E,\ell}$ . . . 524
11.2 Néron-Ogg-Shafarevich and inertia invariants . . . 529
11.3 Good and multiplicative reduction . . . 532
11.4 Additive potentially good reduction . . . 536
11.5 The representation at ℓ . . . 542
11.6 Conductors of mod ℓ representations . . . 545
11.7 The images of $\bar{\rho}_{E,\ell}$ . . . 547
11.8 Absolute irreducibility over $\mathbb{Q}(\sqrt{\ell^*})$ . . . 553
11.9 The Eisenstein case . . . 559
11.10 Serre's conjecture and the optimal level . . . 561
11.11 Exercises . . . 562
11.12 Notes and references . . . 564

IV Modular forms and modular curves 567

12 Modular forms and modular curves 569
12.1 The upper half plane . . . 574
12.2 The modular group and its fundamental domain . . . 576
12.3 Congruence subgroups and their indices . . . 578
12.4 Cusps, widths and elliptic points . . . 580
12.5 The modular curves as compact Riemann surfaces . . . 583
12.6 Modular forms, q-expansions and nebentypus . . . 586
12.7 Level one: Eisenstein series, Δ, j and the valence formula . . . 591
12.8 Forms on $\Gamma_0(N)$: valence, differentials and dimensions . . . 596

Part I

Algebra

Chapter 1

Groups, group actions and matrix groups over finite fields

The paper uses group theory in two ways. Most of the time it is the background language: Galois groups are profinite groups, inertia groups are stabilisers, Tamagawa numbers and component groups are finite abelian groups whose ℓ-parts are taken, and the tame Galois group of $\mathbb{Q}_p$ is a semidirect product. At a few precise places, however, the paper's arguments are statements about specific finite groups: the proof of Proposition prop:ns is a classification of certain subgroups of the group $\mathrm{GL}_2(\mathbb{F}_3)$ of order 48, of their subgroups of determinant one and of their orbits on the four lines of $\mathbb{F}_3^2$; Lemma lem:IV and Remark rem:types are statements about unipotent elements of $\mathrm{GL}_2(\mathbb{F}_3)$; and Lemma lem:h0 uses that $\mathbb{F}_\ell^\times$ is cyclic of order $\ell-1$. This chapter develops the elementary theory from the definitions and then treats $\mathrm{GL}_2(\mathbb{F}_3)$ completely, so that every group-theoretic sentence of the paper can be checked line by line. It relies on no earlier chapter, only on linear algebra over a field and on the first notions of group theory as in Riley-Hobson-Bence.

Core results at a glance

Throughout, F is a field, $\mathbb{F}_q$ a finite field with q elements (q odd when Cartan subgroups appear; the reader may take $q=p$ prime), and the standard models of Convention 1.60 are used for the subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$.

1.1 Conventions. Matrices act on column vectors on the left; $\mathbb{P}^1(F)$ is the set of lines $[v]=Fv$ of F^2, with $\infty=[1:0]=[e_1]$ and $x=[x:1]$, so that $\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)$ acts by $x\mapsto(ax+b)/(cx+d)$; D_n has order $2n$; q is a field size in this chapter and a bad prime in the paper; "the image is X" means "conjugate to the standard model X". Convention 1.1.

1.2 Groups (definition: group, abelian group, subgroup, the subgroup $\langle S\rangle$ generated by S, the order $\#G$ of a group and the order of an element, cyclic group). Definition 1.2.

1.3 Lagrange. For $H\le G$ finite, the left cosets of H partition G into $[G:H]$ sets of $\#H$ elements, so $\#G=[G:H]\,\#H$; the order of every element divides $\#G$. *(proved here)* Proposition 1.3.

1.4 Cyclic groups. Let $C=\langle t\rangle$ have order n. (i) For each $d\mid n$, C has exactly one subgroup of order d, $C[d]=\{x:x^d=1\}=\langle t^{n/d}\rangle$, and every subgroup is of this form.

(ii) $x \mapsto x^m$ has kernel $C[\gcd(m,n)]$ and image $C^m = C^{\gcd(m,n)}$ of index $\gcd(m,n)$; so $[C : C^{\ell^k}] = \ell^{\min(k, v_\ell(n))}$ for a prime ℓ. (iii) The generators are the $\varphi(n)$ elements of order n, and $\mathrm{Aut}(C) \simeq (\mathbb{Z}/n)^\times$ via $t \mapsto t^a$. (iv) A surjection $\chi\colon G \to C$ satisfies $\chi(g)^2 = 1$ for all g iff $n \mid 2$. *(proved here)* Theorem 1.4.

1.5 Normal subgroups and quotients (definition: normal subgroup, quotient, kernel, centre $Z(G)$, centraliser $C_G(S)$, normaliser $N_G(S)$, commutator subgroup $[G,G]$). Definition 1.5.

1.6 Isomorphism theorems. First, $G/\ker f \simeq f(G)$. Second, $HN/N \simeq H/(H \cap N)$ for $H \le G$ and $N \trianglelefteq G$. Third, $(G/N)/(M/N) \simeq G/M$ for $N \le M$ normal. Correspondence: subgroups of G/N correspond to subgroups of G containing N, normal to normal. *(proved here)* Theorem 1.6.

1.7 Index two; image of a kernel. A subgroup of index 2 is normal. If $\rho\colon G \to \Gamma$ and $\delta\colon \Gamma \to A$ are homomorphisms, then $\rho(\ker(\delta \circ \rho)) = \rho(G) \cap \ker\delta$; in particular the image of $\ker(\det \circ \rho)$ is the determinant-one subgroup of $\rho(G)$. *(proved here)* Lemma 1.7.

1.8 Conjugacy classes. The class of g has $[G : C_G(g)]$ elements; H has $[G : N_G(H)]$ conjugates; a subgroup is normal iff it is a union of classes. *(proved here)* Proposition 1.9.

1.9 ℓ-primary parts. For a finite abelian group A and a prime ℓ, $A[\ell^\infty] = \{a : \ell^k a = 0 \text{ for some } k\}$ has order $\ell^{v_\ell(\#A)}$, is the unique Sylow ℓ-subgroup, and $A = \bigoplus_{\ell \mid \#A} A[\ell^\infty]$; Cauchy's theorem holds for A. *(proved here)* Proposition 1.10.

1.10 Direct products. If $H, K \trianglelefteq G$, $H \cap K = 1$, $HK = G$, then $H \times K \simeq G$ by $(h,k) \mapsto hk$. *(proved here)* Proposition 1.12.

1.11 Chinese remainder theorem for groups. $C_m \times C_n \simeq C_{mn}$ iff $\gcd(m,n) = 1$; $\mathbb{Z}/n \simeq \prod_{p \mid n} \mathbb{Z}/p^{v_p(n)}$. *(proved here)* Proposition 1.13.

1.12 Semidirect products (definition: $N \rtimes_\theta H$, with $(n,h)(n',h') = (n\,\theta(h)(n'), hh')$ and $hnh^{-1} = \theta(h)(n)$). Definition 1.14. **Recognition:** if $N \trianglelefteq G$, $H \le G$, $N \cap H = 1$, $NH = G$, then $G \simeq N \rtimes_\theta H$ with θ conjugation; a short exact sequence $1 \to N \to G \to Q \to 1$ splits iff $G \simeq N \rtimes Q$. *(proved here)* Proposition 1.15.

1.13 Normal forms. If $G = \{a^m b^e : 0 \le m < n,\ e \in \{0,1\}\}$ ($2n$ distinct elements) with $a^n = 1$, $bab^{-1} = a^k$, $b^2 = a^c$, the multiplication of G is determined by (n,k,c); two such groups with the same (n,k,c) are isomorphic via $a^m b^e \mapsto a'^m b'^e$. *(proved here)* Lemma 1.17.

1.14 Dihedral groups. $D_n = \langle r, s \mid r^n = s^2 = 1,\ srs^{-1} = r^{-1}\rangle \simeq C_n \rtimes C_2$ has order $2n$; all elements outside $\langle r\rangle$ have order 2; a group of order $2n$ generated by r of order n and s of order 2 with $srs^{-1} = r^{-1}$ is $\simeq D_n$; $D_3 \simeq S_3$, $D_6 \simeq C_2 \times S_3$; D_4 has five involutions. *(proved here)* Definition 1.18, Proposition 1.19.

1.15 The quaternion group. $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$, $i^2 = j^2 = k^2 = ijk = -1$: -1 is the only involution, $Z(Q_8) = [Q_8, Q_8] = \{\pm 1\}$, every subgroup is normal, $Q_8 \not\simeq D_4$; a non-abelian group of order 8 with a unique involution is $\simeq Q_8$. *(proved here)* Definition 1.20, Proposition 1.21.

1.16 The semidihedral group. $SD_{16} = \langle a, x \mid a^8 = x^2 = 1,\ xax^{-1} = a^3\rangle$ has order 16; $(a^i x)^2 = a^{4i}$; it has $1, 5, 6, 4$ elements of orders $1, 2, 4, 8$; its index-2 subgroups are $\langle a\rangle \simeq C_8$,

$\langle a^2, x\rangle \simeq D_4$, $\langle a^2, ax\rangle \simeq Q_8$; a group of order 16 generated by a of order 8 and x of order 2 with $xax^{-1} = a^3$ is $\simeq SD_{16}$. *(proved here)* Definition 1.22, Proposition 1.23.

1.17 Groups of order 8. Every group of order 8 is isomorphic to exactly one of C_8, $C_4 \times C_2$, C_2^3, D_4, Q_8. *(proved here)* Theorem 1.25.

1.18 Group actions (definition: action, orbit Gx, stabiliser G_x, fixed set X^G, transitive, faithful). Definition 1.27.

1.19 Orbit-stabiliser. $gG_x \mapsto gx$ is a bijection $G/G_x \to Gx$; $G_{gx} = gG_xg^{-1}$; $\#X = \sum_i [G : G_{x_i}]$ over orbit representatives. *(proved here)* Theorem 1.28.

1.20 Orbits of a subgroup. If G is transitive on X and $H \leq G$, then H is transitive iff $G = HG_x$; if $H \trianglelefteq G$, the H-orbits are permuted transitively by G and have equal size; if $[G : H] = 2$, either H is transitive or X is the union of two H-orbits of size $\#X/2$, interchanged by $G \setminus H$. *(proved here)* Proposition 1.29.

1.21 Orbit counting. The number of orbits of a finite group on a finite set is $\frac{1}{\#G}\sum_g \#X^g$. *(proved here)* Lemma 1.30.

1.22 Class equation and p-groups. $\#G = \#Z(G) + \sum[G : C_G(g_i)]$; if a p-group acts on X, $\#X \equiv \#X^P \pmod p$; nontrivial p-groups have nontrivial centre; groups of order p^2 are abelian; a group of order p^n has normal subgroups of every order p^k, and subgroups of index p in a p-group are normal. *(proved here)* Theorem 1.31.

1.23 Cauchy. If a prime p divides $\#G$, G has an element of order p. *(proved here)* Theorem 1.32.

1.24 Sylow. Let $\#G = p^a m$, $p \nmid m$. Sylow p-subgroups (order p^a) exist; every p-subgroup lies in one; they are all conjugate; their number $n_p = [G : N_G(P)]$ divides m and is $\equiv 1 \pmod p$; $P \trianglelefteq G$ iff $n_p = 1$. *(proved here)* Theorem 1.33.

1.25 Finite abelian groups. $A \simeq \bigoplus_i \mathbb{Z}/\ell_i^{e_i}$ with the multiset $\{\ell_i^{e_i}\}$ unique; equivalently $A \simeq \bigoplus \mathbb{Z}/d_i$ with $1 < d_1 \mid \cdots \mid d_r$ unique; the numbers $\#A[\ell^k]$ determine $A[\ell^\infty]$. *(proved here)* Theorem 1.35.

1.26 Cyclicity criteria. A finite abelian group is cyclic iff $\#A[\ell] \leq \ell$ for all primes ℓ; every finite subgroup of $K^\times$, K a field, is cyclic; so $\mathbb{F}_q^\times$ and $\mu_n(K)$ are cyclic. *(proved here)* Corollary 1.36.

1.27 Counting torsion. $\#A[n] = \#A/nA$; for $A \simeq \bigoplus_i \mathbb{Z}/\ell^{e_i}$, $\#A[\ell^k] = \ell^{\sum_i \min(k,e_i)}$. *(proved here)* Proposition 1.37.

1.28 Linear groups (definition: $\mathrm{GL}_2(F)$, $\mathrm{SL}_2(F)$, $\mathrm{PGL}_2(F) = \mathrm{GL}_2(F)/F^\times I$, $\mathrm{PSL}_2(F) = \mathrm{SL}_2(F)/\{\pm I\}$). Definition 1.40. $Z(\mathrm{GL}_2(F)) = F^\times I$, $Z(\mathrm{SL}_2(F)) = \{\pm I\}$; $\mathrm{GL}_2(F) \simeq \mathrm{SL}_2(F) \rtimes F^\times$; $\mathrm{SL}_2(F)$ is generated by elementary matrices; for $\mathrm{char}\, F \neq 2$, $-I$ is the only involution of $\mathrm{SL}_2(F)$; $[\mathrm{PGL}_2(F) : \mathrm{PSL}_2(F)] = [F^\times : (F^\times)^2]$. *(proved here)* Proposition 1.41.

1.29 Companion form. Two non-scalar matrices in $\mathrm{GL}_2(F)$ are conjugate iff they have the same characteristic polynomial; the centraliser of a non-scalar g is $F[g]^\times$. *(proved here)* Lemma 1.42.

1.30 Orders. $\#\,\mathrm{GL}_2(\mathbb{F}_q) = q(q-1)^2(q+1)$, $\#\,\mathrm{SL}_2(\mathbb{F}_q) = \#\,\mathrm{PGL}_2(\mathbb{F}_q) = q(q^2-1)$, $\#\,\mathrm{PSL}_2(\mathbb{F}_q) = q(q^2-1)/\gcd(2,q-1)$ ($48, 24, 24, 12$ for $q=3$). *(proved here)* Proposition 1.43.

1.31 The projective line. $\mathrm{GL}_2(F)$ acts on $\mathbb{P}^1(F)$ with kernel $F^\times I$; $\mathrm{PGL}_2(F)$ is sharply 3-transitive; the stabiliser of ∞ is the upper triangular group $\mathrm{B}(F)$; $\mathrm{SL}_2(F)$ is 2-transitive; $\#\mathbb{P}^1(\mathbb{F}_q) = q+1$. *(proved here)* Proposition 1.44.

1.32 Borel subgroups (definition: the stabiliser B_L of a line L; U the upper unitriangular group, T the diagonal group). Definition 1.45. $\mathrm{B} = \mathrm{U} \rtimes \mathrm{T}$, $\#\mathrm{B}(\mathbb{F}_q) = q(q-1)^2$, Borel subgroups are conjugate and self-normalising, and a subgroup stabilises a line iff it lies in a Borel subgroup; $\mathrm{B}(\mathbb{F}_3) \simeq C_2 \times S_3 \simeq D_6$. *(proved here)* Proposition 1.46.

1.33 Unipotent elements (definition: $(u-1)^2 = 0$). Definition 1.47. A unipotent $u \neq 1$ is conjugate to $\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ and fixes exactly one line, pointwise; in characteristic p the unipotents $\neq 1$ are exactly the elements of p-power order $\neq 1$, and have order p; $-u$ fixes no nonzero vector ($\mathrm{char}\, F \neq 2$), stabilises one line and has order $2p$; the stabiliser of a nonzero vector v in $\mathrm{SL}_2(F)$ is the group $\mathrm{U}_{[v]} \simeq (F,+)$; in $\mathrm{GL}_2(\mathbb{F}_3)$ the 8 elements of order 3 are the nontrivial unipotents, form one class, lie in the four Sylow 3-subgroups U_L, and generate $\mathrm{SL}_2(\mathbb{F}_3)$; the 8 elements of order 6 are the $-u$. *(proved here)* Proposition 1.48.

1.34 Commutators in a Borel subgroup. For $H \leq \mathrm{B}(K)$, $[H,H] \leq \mathrm{U}(K)$. If $\mathrm{char}\, K = p$: a subgroup of $\mathrm{B}(K)$ of order prime to p is abelian, and a finite subgroup of $\mathrm{GL}_2(K)$ whose commutator subgroup is not a p-group stabilises no line of K^2. *(proved here)* Lemma 1.50.

1.35 PGL_2 in small characteristic. $\mathrm{PGL}_2(\mathbb{F}_3) \simeq S_4$ and $\mathrm{PSL}_2(\mathbb{F}_3) \simeq A_4$ through the four lines; for $g \in \mathrm{GL}_2(\mathbb{F}_3)$, $\det g$ is the sign of the permutation of the lines. *(proved here)* $\mathrm{PGL}_2(\mathbb{F}_5) \simeq S_5$, $\mathrm{PSL}_2(\mathbb{F}_5) \simeq A_5$. *(proof sketched here)* $\mathrm{PSL}_2(\mathbb{F}_q)$ is simple for $q \geq 4$, and $\mathrm{PSL}_2(\mathbb{F}_7) \simeq \mathrm{GL}_3(\mathbb{F}_2)$. *(stated; reference)* Theorem 1.52.

1.36 Cartan subgroups (definition, q odd, ε a non-square: $C_s = \{\mathrm{diag}(a,d)\}$; $C_{ns} = \{\left(\begin{smallmatrix}a&\varepsilon b\\b&a\end{smallmatrix}\right) : (a,b) \neq (0,0)\} \simeq \mathbb{F}_q[\sqrt{\varepsilon}]^\times$). Definition 1.54. $N(C_s) = C_s \cup wC_s$ is the stabiliser of $\{[e_1],[e_2]\}$; $N(C_{ns}) = C_{ns} \cup C_{ns}\sigma$ with $\sigma = \mathrm{diag}(1,-1)$ and $\sigma c \sigma^{-1} = c^q$; C_{ns} is cyclic of order q^2-1; all split, respectively all nonsplit, Cartan subgroups are conjugate. *(proved here)* Proposition 1.55.

1.37 Cartan facts. $\#C_s = (q-1)^2$, $\#N_s = 2(q-1)^2$, $\#C_{ns} = q^2-1$, $\#N_{ns} = 2(q^2-1)$; elements of $N_s \setminus C_s$ and of $N_{ns} \setminus C_{ns}$ have trace 0, with $(c\sigma)^2 = \det(c) I$; $\det(C_{ns}) = \mathbb{F}_q^\times$; the determinant-one subgroups have orders $q-1$, $2(q-1)$, $q+1$, $2(q+1)$; orbits on $\mathbb{P}^1(\mathbb{F}_q)$: C_s: $1, 1, q-1$; N_s: $2, q-1$; B: $1, q$; C_{ns} and N_{ns} transitive. *(proved here)* Proposition 1.56.

1.38 Dickson. For ℓ odd and $G \leq \mathrm{GL}_2(\mathbb{F}_\ell)$ with image $\bar{G}$ in $\mathrm{PGL}_2(\mathbb{F}_\ell)$: if $\ell \mid \#G$, then $G \supseteq \mathrm{SL}_2(\mathbb{F}_\ell)$ or G lies in a Borel subgroup; if $\ell \nmid \#G$, then $\bar{G}$ is cyclic and G lies in a Cartan subgroup, or $\bar{G}$ is dihedral and G lies in the normaliser of a Cartan subgroup but not in the Cartan subgroup, or $\bar{G} \simeq A_4, S_4, A_5$. *(stated; reference; part (a) for $\ell = 3$ is proved in Proposition 1.61, and the case needed by the paper in Theorem 1.65)* Theorem 1.57.

1.39 Conjugacy classes of $\mathrm{GL}_2(\mathbb{F}_3)$. Order 48, centre $\{\pm I\}$, commutator subgroup $\mathrm{SL}_2(\mathbb{F}_3)$, eight classes, of sizes $1, 1, 12, 8, 6, 8, 6, 6$ with representatives $I, -I, \sigma, u, J, -u, \left(\begin{smallmatrix}1&-1\\1&1\end{smallmatrix}\right), \left(\begin{smallmatrix}0&1\\1&1\end{smallmatrix}\right)$ of orders $1, 2, 2, 3, 4, 6, 8, 8$. *(proved here)* Proposition 1.59.

1.40 Standard models. $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ (the paper's J), $\sigma = \mathrm{diag}(1,-1)$, $w = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, $u = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$; $C_s(\mathbb{F}_3) = \{\mathrm{diag}(\pm 1, \pm 1)\}$, $N_s(\mathbb{F}_3) = \langle J, \sigma \rangle$, $C_{ns}(\mathbb{F}_3) = \{\left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right)\}$, $N_{ns}(\mathbb{F}_3) = C_{ns}(\mathbb{F}_3) \cup C_{ns}(\mathbb{F}_3)\sigma$, $Q_8 = \{\pm I, \pm J, \pm\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right), \pm\left(\begin{smallmatrix} 1 & -1 \\ -1 & -1 \end{smallmatrix}\right)\}$, $C_4 = \langle J \rangle$. Convention 1.60.

1.41 Subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$. There are 55 subgroups in 16 conjugacy classes (table); 9 classes have surjective determinant, and all of these except $C_{ns}(\mathbb{F}_3)$ contain an element of determinant -1 and trace 0; a subgroup of order divisible by 3 contains $\mathrm{SL}_2(\mathbb{F}_3)$ or stabilises a line. *(proved here for the rows used; the table checked by computer)* Proposition 1.61.

1.42 $\mathrm{SL}_2(\mathbb{F}_3)$. Order 24; $-I$ its only involution; its elements of order dividing 4 form its unique Sylow 2-subgroup Q_8, normal in $\mathrm{GL}_2(\mathbb{F}_3)$; $\mathrm{SL}_2(\mathbb{F}_3) = Q_8 \rtimes \langle u \rangle$ with u permuting i, j, k cyclically; $[\mathrm{SL}_2(\mathbb{F}_3), \mathrm{SL}_2(\mathbb{F}_3)] = Q_8$; no subgroup of order 12; $\mathrm{GL}_2(\mathbb{F}_3)/Q_8 \simeq S_3$; Q_8 is transitive on the four lines. *(proved here)* Proposition 1.62.

1.43 $N_s(\mathbb{F}_3)$. $N_s(\mathbb{F}_3) = \langle J, \sigma \rangle \simeq D_4$; its elements of determinant -1 are $\pm\sigma, \pm w$, of trace 0; it has 3 conjugates; $N_s(\mathbb{F}_3) \cap \mathrm{SL}_2(\mathbb{F}_3) = \langle J \rangle \simeq C_4$; its orbits on the four lines are $\{\infty, 0\}$ and $\{1, -1\}$, and $\langle J \rangle$ has the same orbits; it stabilises no line of $\overline{\mathbb{F}}_3^2$, while $\langle J \rangle$ stabilises the two lines of $\mathbb{F}_9^2$ spanned by $(\pm i, 1)$; $N_s(\mathbb{F}_3)$ has index 2 in $N_{ns}(\mathbb{F}_3)$. *(proved here)* Proposition 1.63.

1.44 $N_{ns}(\mathbb{F}_3)$. $C_{ns}(\mathbb{F}_3) = \langle a \rangle \simeq C_8$ with $a = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$; $N_{ns}(\mathbb{F}_3) = \langle a, \sigma \rangle \simeq SD_{16}$, $\sigma a \sigma^{-1} = a^3$; it is a Sylow 2-subgroup of $\mathrm{GL}_2(\mathbb{F}_3)$; $N_{ns}(\mathbb{F}_3) \cap \mathrm{SL}_2(\mathbb{F}_3) = Q_8$; its elements of determinant -1 and trace 0 are $\pm\sigma, \pm w$, and $C_{ns}(\mathbb{F}_3)$ has none; $C_{ns}(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ and Q_8 are transitive on the four lines. *(proved here)* Proposition 1.64.

1.45 The three images. If $H \leq \mathrm{GL}_2(\mathbb{F}_3)$ has $\det(H) = \mathbb{F}_3^\times$, stabilises no line of $\mathbb{F}_3^2$, and contains an element of determinant -1 and trace 0, then H is conjugate to exactly one of $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$, $N_s(\mathbb{F}_3)$; the determinant-one subgroups are $\mathrm{SL}_2(\mathbb{F}_3)$, Q_8, $\langle J \rangle$; the first two stabilise no line of $\overline{\mathbb{F}}_3^2$, the third is abelian. *(proved here)* Theorem 1.65.

1.46 Orbit dichotomy. For such H: H is conjugate to $N_s(\mathbb{F}_3)$ iff it has two orbits of size 2 on the four lines, iff it is not transitive, iff $H \cap \mathrm{SL}_2(\mathbb{F}_3)$ is abelian, iff $H \cap \mathrm{SL}_2(\mathbb{F}_3)$ stabilises a line of $\overline{\mathbb{F}}_3^2$. *(proved here)* Corollary 1.66.

1.47 Determinant -1, trace 0. For q odd, $g \in \mathrm{GL}_2(\mathbb{F}_q)$ has $\det g = -1$ and $\mathrm{tr}\, g = 0$ iff it is conjugate to σ; these $q(q+1)$ elements have order 2 and fix exactly two lines; in $\mathrm{GL}_2(\mathbb{F}_3)$, B, N_s, N_{ns}, C_s, C_{ns}, SL_2 there are $12, 6, 4, 4, 2, 0, 0$ of them. *(proved here)* Proposition 1.68.

1.48 Images in S_4. Under $\mathrm{PGL}_2(\mathbb{F}_3) \simeq S_4$: $\mathrm{GL}_2, \mathrm{SL}_2, N_{ns}, Q_8, N_s, C_{ns}, C_s, \langle J \rangle, \mathrm{B}, \mathrm{U}$ map onto S_4, A_4, D_4, the normal V_4, a non-normal V_4, C_4, $\langle$transposition$\rangle$, $\langle$double transposition$\rangle$, S_3, A_3. *(proved here)* Proposition 1.71.

1.49 Inverse limits (definition: $\varprojlim G_n = \{(g_n) : \pi_n(g_{n+1}) = g_n\}$, profinite group). Definition 1.73. The inverse limit is a closed subgroup of $\prod G_n$, compact and Hausdorff, with the universal property. *(proved here, except Tychonoff's theorem: stated; reference)* Proposition 1.75.

1.50 Profinite groups. With $U_n = \ker(G \to G_n)$: the U_n are a basis of neighbourhoods of 1; open subgroups are the closed subgroups of finite index; continuous maps to finite groups

factor through some G/U_n; closed subgroups and quotients by closed normal subgroups are profinite; continuous images in Hausdorff groups are closed; a continuous homomorphism from a pro-p group to a finite group of order prime to p is trivial. *(proved here)* Profinite iff compact, Hausdorff and totally disconnected. *(stated; reference)* Proposition 1.77.

1.51 $\mathrm{GL}_2(\mathbb{Z}_\ell)$**.** $\mathrm{GL}_2(\mathbb{Z}_\ell) = \varprojlim \mathrm{GL}_2(\mathbb{Z}/\ell^n)$; the reduction maps are surjective, with kernels isomorphic to $(M_2(\mathbb{F}_\ell), +)$, so $\#\,\mathrm{GL}_2(\mathbb{Z}/\ell^n) = \ell^{4(n-1)}(\ell^2-1)(\ell^2-\ell)$; the kernel $\Gamma(\ell) = \ker(\mathrm{GL}_2(\mathbb{Z}_\ell) \to \mathrm{GL}_2(\mathbb{F}_\ell))$ is pro-ℓ, and torsion-free if ℓ is odd, so a finite subgroup of $\mathrm{GL}_2(\mathbb{Z}_\ell)$ maps isomorphically into $\mathrm{GL}_2(\mathbb{F}_\ell)$ for ℓ odd. *(proved here)* Proposition 1.78.

1.1 Groups, subgroups, cosets, quotients and cyclic groups

This section fixes the conventions of the chapter and proves the basic facts about cosets, quotients and cyclic groups. In the paper they appear in three places: the image of the absolute Galois group of $\mathbb{Q}(\sqrt{-3})$ is a determinant-one subgroup (Proposition prop:ns, through Lemma 1.7); for an odd prime ℓ, a character of $G_{\mathbb{Q}}$ onto the cyclic group $\mathbb{F}_\ell^\times$ with square 1 forces $\ell = 3$ (Lemma lem:h0, through Theorem 1.4); and the "ℓ-part" of a finite abelian group (Definition def:terms, Lemma lem:tamfactor, through Proposition 1.10).

Convention 1.1. The following conventions hold in this chapter and are inherited by the book.

(C1) Matrices act on column vectors on the left. For $v \in F^2 \setminus \{0\}$ the line through v is $[v] = Fv$, and $\mathbb{P}^1(F)$ is the set of lines of F^2, with coordinates $[x : y]$. We write $\infty = [1 : 0] = [e_1]$ and identify $[x : 1]$ with $x \in F$. Then $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ acts by the Möbius formula $g \cdot x = (ax + b)/(cx + d)$, because $g\binom{x}{1} = \binom{ax+b}{cx+d}$.

(C2) Conjugation is $g \cdot h = ghg^{-1}$. In a semidirect product $N \rtimes H$ the group H acts on N, and $hnh^{-1} = \theta(h)(n)$.

(C3) C_n, or $\mathbb{Z}/n$ when written additively, is the cyclic group of order n; D_n is the dihedral group of order $2n$ (so D_4 has order 8; Dummit and Foote write D_8); $V_4 = C_2 \times C_2$; Q_8 is the quaternion group; SD_{16} is the semidihedral group of order 16; S_n and A_n are the symmetric and alternating groups.

(C4) $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ is a field: an integer prime to p is invertible modulo p by Bezout's identity. $\mathbb{F}_q$ is a finite field with q elements, of characteristic p with q a power of p (Chapter 2 constructs it); the reader may take $q = p$ throughout. Whenever Cartan subgroups are discussed q is odd. In this chapter q is a field size; in the paper q is a bad prime of E (convention B-C1). The two meet only in $\mathrm{GL}_2(\mathbb{F}_3)$, where the field size is $\ell = 3$.

(C5) "The image is $N_s(\mathbb{F}_3)$" always means "the image is conjugate in $\mathrm{GL}_2(\mathbb{F}_3)$ to $N_s(\mathbb{F}_3)$"; the standard models of Convention 1.60 are fixed once and for all, and similarly for $N_{ns}(\mathbb{F}_3)$, C_s, C_{ns}, B, U.

Definition 1.2. A *group* is a set G with an associative composition $G \times G \to G$, $(g, h) \mapsto gh$, an identity element 1 and inverses. It is *abelian* if $gh = hg$ for all g, h; abelian groups are often written additively, with 0 and $-a$. A *subgroup* $H \leq G$ is a nonempty subset closed under products and inverses. The subgroup $\langle S \rangle$ generated by a subset S is the intersection of all subgroups containing S, that is, the set of finite products of elements of S and their inverses. The *order* of G is its cardinality $\#G$; the order of $g \in G$ is the least $n \geq 1$ with $g^n = 1$ (or ∞), which is $\#\langle g \rangle$. A group is *cyclic* if $G = \langle g \rangle$ for some g. Examples: $(\mathbb{Z}, +)$; $\mathbb{Z}/n$; the symmetric group S_n; the group $\mathrm{GL}_2(F)$ of invertible 2×2 matrices over a field F; the multiplicative group $F^\times$.

Proposition 1.3 (Lagrange)**.** *Let $H \leq G$ with G finite. The left cosets gH partition G, each has $\#H$ elements, and $\#G = [G : H] \cdot \#H$, where $[G : H]$ is the number of cosets. Consequently the order of every element of G divides $\#G$, and $g^{\#G} = 1$ for every $g \in G$.*

Proof. Every g lies in gH. If $x \in gH \cap g'H$, say $x = gh = g'h'$, then $g' = ghh'^{-1} \in gH$, so $g'H \subseteq gH$, and symmetrically; so two cosets are equal or disjoint. The map $H \to gH$, $h \mapsto gh$, is bijective (its inverse is multiplication by g^{-1}). Counting gives $\#G = [G : H]\,\#H$. Applied to $H = \langle g \rangle$, the order of g divides $\#G$, and then $g^{\#G} = 1$. □

Theorem 1.4. *Let $C = \langle t \rangle$ be cyclic of order n.*

(i) Every subgroup of C is cyclic. For each $d \mid n$ there is exactly one subgroup of order d, namely $C[d] = \{x \in C : x^d = 1\} = \langle t^{n/d} \rangle = C^{n/d}$, the set of (n/d)-th powers.

(ii) For $m \geq 1$ the map $x \mapsto x^m$ is an endomorphism of C with kernel $C[\gcd(m,n)]$, of order $\gcd(m,n)$, and image $C^m = C^{\gcd(m,n)}$, of index $\gcd(m,n)$. In particular, for a prime ℓ and $k \geq 0$, $[C : C^{\ell^k}] = \ell^{\min(k, v_\ell(n))}$; and for $k \leq v_\ell(n)$, an element $x \in C$ is an ℓ^k-th power iff its image in $C/C^{\ell^{v_\ell(n)}} \simeq \mathbb{Z}/\ell^{v_\ell(n)}$ is divisible by ℓ^k.

(iii) The generators of C are the $\varphi(n)$ elements t^a with $\gcd(a,n) = 1$, which are its elements of order n. The map $(\mathbb{Z}/n)^\times \to \mathrm{Aut}(C)$, $a \mapsto (t \mapsto t^a)$, is an isomorphism. $\mathrm{Aut}(\mathbb{Z}) = \{\pm 1\}$.

(iv) Let $\chi \colon G \to C$ be a surjective homomorphism from any group. Then $\chi(g)^2 = 1$ for all $g \in G$ if and only if $n \mid 2$.

Proof. The map $\mathbb{Z} \to C$, $a \mapsto t^a$, is a surjective homomorphism with kernel $n\mathbb{Z}$ (if $t^a = 1$, write $a = bn + r$ with $0 \leq r < n$; then $t^r = 1$ and $r = 0$ by minimality of n). So $t^a = t^b$ iff $a \equiv b \pmod{n}$, and the order of t^a is $n/\gcd(a,n)$: indeed $(t^a)^k = 1$ iff $n \mid ak$ iff $\frac{n}{\gcd(a,n)} \mid k$.

(i) Let $H \leq C$, $H \neq 1$, and let a be the least positive integer with $t^a \in H$. For $t^b \in H$ write $b = ca + r$, $0 \leq r < a$; then $t^r = t^b(t^a)^{-c} \in H$, so $r = 0$. Hence $H = \langle t^a \rangle$, and $a \mid n$ (take $b = n$). So $H = \langle t^a \rangle$ has order n/a: the subgroups are the $\langle t^{n/d} \rangle$ for $d \mid n$, one for each order d. The subgroup $\langle t^{n/d} \rangle$ consists of (n/d)-th powers and has order d, so its elements satisfy $x^d = 1$; conversely $x = t^b$ with $x^d = 1$ means $n \mid bd$, that is $\frac{n}{d} \mid b$. So $C[d] = \langle t^{n/d} \rangle = C^{n/d}$.

(ii) The map is a homomorphism because C is abelian. Let $g = \gcd(m,n)$. Its kernel is $C[m]$; and $x^m = 1$ iff $x^g = 1$ (write $g = am + bn$, so $x^g = (x^m)^a (x^n)^b$), so the kernel is $C[g]$, of order g by (i). By the first isomorphism theorem (Theorem 1.6, whose proof does not use this one) the image has order n/g; it is contained in C^g (as $g \mid m$), which has order n/g by (i) applied to $d = n/g$; so $C^m = C^g$, of index g. For $m = \ell^k$, $g = \gcd(\ell^k, n) = \ell^{\min(k, v_\ell(n))}$.

For the last statement put $e = v_\ell(n)$ and fix $k \leq e$. Since $\ell^k \mid \ell^e$, every ℓ^e-th power is an ℓ^k-th power: $C^{\ell^e} \subseteq C^{\ell^k}$. Let $\pi \colon C \to \bar{C} = C/C^{\ell^e}$ be the projection. By what was just proved, $\bar{C}$ has order $[C : C^{\ell^e}] = \ell^e$; it is cyclic, generated by $\pi(t)$, and $\pi(t) \mapsto 1$ identifies it with $\mathbb{Z}/\ell^e$. Under this identification $\pi(C^{\ell^k}) = \bar{C}^{\ell^k}$ (the image of an ℓ^k-th power is an ℓ^k-th power, and every ℓ^k-th power $\pi(y)^{\ell^k} = \pi(y^{\ell^k})$ is such an image) becomes $\ell^k\mathbb{Z}/\ell^e$, the multiples of ℓ^k. Because C^{ℓ^k} contains the kernel C^{ℓ^e} of π, it equals the full preimage $\pi^{-1}(\pi(C^{\ell^k}))$ (Theorem 1.6(iv)). Hence $x \in C^{\ell^k}$ iff $\pi(x) \in \ell^k\mathbb{Z}/\ell^e$, as claimed.

(iii) t^a generates iff its order $n/\gcd(a,n)$ is n. An automorphism α is determined by $\alpha(t)$, which must be a generator t^a; conversely $x \mapsto x^a$ with $\gcd(a,n) = 1$ is a bijective endomorphism by (ii). Composition corresponds to multiplication of exponents. For $\mathbb{Z}$, an automorphism sends the generator 1 to a generator, ± 1.

(iv) If $n \mid 2$, every element of C satisfies $x^2 = 1$. Conversely, if $\chi(g)^2 = 1$ for all g, then, χ being surjective, every $x \in C$ satisfies $x^2 = 1$; in particular $t^2 = 1$ and $n \mid 2$. □

For example, let $C = \mathbb{Z}/12$ (written additively, so that "m-th powers" are multiples of m) and $\ell = 2$, so $v_2(12) = 2$. Then $2C = \{0, 2, \ldots, 10\}$ has index 2, $4C = \{0, 4, 8\}$ has index 4, and $8C = \gcd(8,12)C = 4C$ again has index $4 = 2^{\min(3,2)}$: once k passes $v_\ell(n)$, raising to higher ℓ-powers removes nothing more, because the ℓ-part of C has already been killed and the prime-to-ℓ part is unaffected. The quotient $C/4C \simeq \mathbb{Z}/4$ remembers exactly the 2-part of C, and

$x \in C$ is a multiple of 2 iff its image in $\mathbb{Z}/4$ is. Part (iv) is the form in which this is used: a character of $G_{\mathbb{Q}}$ onto $\mathbb{F}_\ell^\times$, cyclic of order $\ell - 1$ (Corollary 1.36), can be quadratic only if $\ell - 1 \mid 2$, that is, for an odd prime ℓ, only if $\ell = 3$.

Definition 1.5. A subgroup $N \leq G$ is *normal*, $N \trianglelefteq G$, if $gNg^{-1} = N$ for all $g \in G$. Then the cosets gN form a group G/N, the *quotient*, with $(gN)(g'N) = gg'N$, and $G \to G/N$ is the *canonical projection*. A *homomorphism* $f\colon G \to H$ satisfies $f(gg') = f(g)f(g')$; its *kernel* $\ker f = f^{-1}(1)$ is normal and its image $f(G)$ is a subgroup. A group is *simple* if it is nontrivial and has no normal subgroups other than 1 and itself. The *centre* is $Z(G) = \{z : zg = gz\ \forall g\}$; for $S \subseteq G$, the *centraliser* is $C_G(S) = \{g : gs = sg\ \forall s \in S\}$ and the *normaliser* is $N_G(S) = \{g : gSg^{-1} = S\}$. The *conjugacy class* of g is $\{hgh^{-1} : h \in G\}$. The *commutator subgroup* $[G, G]$ is generated by the commutators $[g, h] = ghg^{-1}h^{-1}$; it is normal, $G/[G, G]$ is abelian (the *abelianisation*), and $[G, G] \leq N$ for a normal N iff G/N is abelian.

Normality is exactly what makes the coset product meaningful. Read $(gN)(g'N)$ as the set of all products xy with $x \in gN$, $y \in g'N$. Using $Ng' = g'(g'^{-1}Ng') = g'N$ we get $gNg'N = gg'NN = gg'N$, so the product of two cosets is again a coset and does not depend on the representatives chosen. Without normality this fails: in S_3 take $N = \langle(12)\rangle$. Then $(13)N = \{(13), (123)\}$, and $(13)N \cdot (13)N$ contains both $(13)(13) = 1$ and $(123)(13) = (23)$ (permutations composed from right to left), which lie in the different cosets N and $(23)N$. By contrast $A_3 = \langle(123)\rangle$ has index 2 in S_3, hence is normal (Lemma 1.7), and $S_3/A_3 \simeq C_2$ records the sign of a permutation. The kernel of a homomorphism is normal because $f(gkg^{-1}) = f(g)f(g)^{-1} = 1$ for $k \in \ker f$; conversely every normal N is the kernel of $G \to G/N$, so normal subgroups and kernels are the same thing. The last statement of the definition holds because G/N is abelian iff $ghN = hgN$ for all g, h, iff $g^{-1}h^{-1}gh \in N$ for all g, h, and as g, h range over G so do g^{-1}, h^{-1}; so this says that N contains every commutator, hence the subgroup $[G, G]$ they generate.

Theorem 1.6 (Isomorphism theorems)**.** *(i) A homomorphism $f\colon G \to H$ induces an isomorphism $G/\ker f \simeq f(G)$, $g \ker f \mapsto f(g)$.*

(ii) If $H \leq G$ and $N \trianglelefteq G$, then HN is a subgroup, $H \cap N \trianglelefteq H$, and $HN/N \simeq H/(H \cap N)$.

(iii) If $N \leq M$ are normal subgroups of G, then $M/N \trianglelefteq G/N$ and $(G/N)/(M/N) \simeq G/M$.

(iv) (Correspondence) For $N \trianglelefteq G$, $K \mapsto K/N$ is an inclusion-preserving bijection from the subgroups of G containing N to the subgroups of G/N, under which normal subgroups correspond to normal subgroups.

Proof. (i) $f(g) = f(g')$ iff $g^{-1}g' \in \ker f$ iff $g \ker f = g' \ker f$; so the map is well defined and injective; it is a surjective homomorphism onto $f(G)$. (ii) $hnh'n' = hh'(h'^{-1}nh')n' \in HN$ and $(hn)^{-1} = h^{-1}(hn^{-1}h^{-1}) \in HN$, so HN is a subgroup. The homomorphism $H \to HN/N$, $h \mapsto hN$, is surjective (as $hnN = hN$) with kernel $H \cap N$; apply (i). (iii) The map $G/N \to G/M$, $gN \mapsto gM$, is a well-defined surjective homomorphism with kernel M/N; apply (i). (iv) The inverse bijection sends $\bar{K} \leq G/N$ to its preimage under the projection π; $\pi(\pi^{-1}(\bar{K})) = \bar{K}$ as π is surjective, and $\pi^{-1}(\pi(K)) = KN = K$ when $N \leq K$. Normality is preserved in both directions since $\pi(gKg^{-1}) = \pi(g)\pi(K)\pi(g)^{-1}$. □

Lemma 1.7. *(i) A subgroup H of index 2 in G is normal, and is the kernel of a surjection $G \to C_2$.*

(ii) Let $\rho\colon G \to \Gamma$ and $\delta\colon \Gamma \to A$ be homomorphisms and $G_0 = \ker(\delta \circ \rho)$. Then $\rho(G_0) = \rho(G) \cap \ker \delta$. In particular, if $\rho\colon G \to \mathrm{GL}_2(F)$ and $G_0 = \ker(\det \circ \rho)$, then (with $\mathrm{SL}_2(F)$ the group of matrices of determinant 1, Definition 1.40) $\rho(G_0) = \rho(G) \cap \mathrm{SL}_2(F)$ is the determinant-one subgroup of the image.

Proof. (i) There are two left cosets; one is H, so the other is the complement $G \setminus H$. The same holds for the right cosets. For $g \in H$ we have $gH = H = Hg$, and for $g \notin H$ both gH and Hg are cosets different from H, hence both equal $G \setminus H$. So $gH = Hg$, that is $gHg^{-1} = H$, for every g, and $H \trianglelefteq G$. The quotient G/H has order 2, so it is C_2, and the projection $G \to G/H$ is the required surjection with kernel H. (ii) If $g \in G_0$, then $\rho(g) \in \rho(G)$ and $\delta(\rho(g)) = 1$. Conversely, if $\gamma \in \rho(G) \cap \ker \delta$, write $\gamma = \rho(g)$; then $\delta(\rho(g)) = 1$, so $g \in G_0$ and $\gamma \in \rho(G_0)$. □

In the paper 1.8. The proof of Proposition prop:ns begins: "Since $\det \bar\rho_{E,3} = \chi_{-3}$ cuts out $\mathbb{Q}(\sqrt{-3})$, the image of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$ is the subgroup of determinant 1 of the image H of $\bar\rho_{E,3}$." This is Lemma 1.7(ii) with $G = G_{\mathbb{Q}}$, $\rho = \bar\rho_{E,3}$, $\delta = \det$: the kernel of $\det \circ \bar\rho_{E,3} = \chi_{-3}$ is $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$ by Galois theory (Chapter 5), and the identity $\det \bar\rho_{E,3} = \bar\chi_3$, $\bar\chi_3 = \chi_{-3}$, is Chapter 9 and Chapter 11. Since $\mathbb{F}_3^\times = \{\pm 1\}$, the determinant-one subgroup has index 1 or 2 in H, and index 2 when $\det(H) = \mathbb{F}_3^\times$.

Proposition 1.9. *Conjugacy is an equivalence relation on G. For G finite, the class of g has $[G : C_G(g)]$ elements, and a subgroup H has exactly $[G : N_G(H)]$ conjugates gHg^{-1}. A subgroup is normal iff it is a union of conjugacy classes.*

Proof. Reflexivity, symmetry and transitivity follow from $g = 1g1^{-1}$, $h = x^{-1}(xhx^{-1})x$ and $y(xgx^{-1})y^{-1} = (yx)g(yx)^{-1}$. The map $G \to \{xgx^{-1}\}$, $x \mapsto xgx^{-1}$, satisfies $xgx^{-1} = ygy^{-1}$ iff $y^{-1}x \in C_G(g)$ iff $xC_G(g) = yC_G(g)$; so the class is in bijection with $G/C_G(g)$. The same argument with $x \mapsto xHx^{-1}$ and $N_G(H)$ counts the conjugates of H. A subgroup N satisfies $gNg^{-1} \subseteq N$ for all g iff it contains the class of each of its elements; and $gNg^{-1} \subseteq N$ for all g implies equality (apply it to g^{-1}). (This is the special case of Theorem 1.28 for the conjugation action.) □

Proposition 1.10. *Let A be a finite abelian group, written additively, and ℓ a prime.*

(i) (Cauchy for abelian groups) If $\ell \mid \#A$, then A has an element of order ℓ.

(ii) If $\#A = mn$ with $\gcd(m,n) = 1$, then $A = A[m] \oplus A[n]$, where $A[m] = \{a : ma = 0\}$, and $\#A[m] = m$, $\#A[n] = n$.

(iii) The ℓ-primary part $A[\ell^\infty] = \{a : \ell^k a = 0 \text{ for some } k\}$ equals $A[\ell^{v_\ell(\#A)}]$, has order $\ell^{v_\ell(\#A)}$, and is the unique Sylow ℓ-subgroup of A (the unique subgroup of order $\ell^{v_\ell(\#A)}$; Sylow subgroups of arbitrary finite groups are treated in Theorem 1.33); every ℓ-power-order subgroup lies in it.

(iv) $A = \bigoplus_{\ell \mid \#A} A[\ell^\infty]$, and the projection onto $A[\ell^\infty]$ is multiplication by an integer e_ℓ with $e_\ell \equiv 1 \pmod{\ell^{v_\ell(\#A)}}$ and $e_\ell \equiv 0$ modulo $\#A/\ell^{v_\ell(\#A)}$.

(v) The exponent of A (the least $e \geq 1$ with $eA = 0$) divides $\#A$ and has the same prime divisors.

Proof. (i) Induction on $\#A$. Pick $a \neq 0$ of order k. If $\ell \mid k$, then $(k/\ell)a$ has order ℓ. Otherwise ℓ divides $\#(A/\langle a\rangle) = \#A/k < \#A$, and by induction there is $b \in A$ whose class $\bar{b}$ has order ℓ. If b has order k', then $k'\bar{b} = 0$, so $\ell \mid k'$, and $(k'/\ell)b$ has order ℓ.

(ii) Write $1 = xm + yn$ with $x, y \in \mathbb{Z}$. For $a \in A$, $a = xma + yna$, and $n(xma) = x(mn)a = 0$ by Lagrange, so $xma \in A[n]$; similarly $yna \in A[m]$. If $a \in A[m] \cap A[n]$, then $a = xma + yna = 0$. So $A = A[m] \oplus A[n]$ and $\#A[m] \cdot \#A[n] = \#A = mn$. By (i), no prime p dividing n divides $\#A[m]$: otherwise $A[m]$ would contain an element a of order p, and then $na = 0$ as $p \mid n$, so $a \in A[m] \cap A[n] = 0$. Hence $\#A[m]$, which divides mn, is prime to n and so divides m. Symmetrically $\#A[n]$ divides n. As the product of the two orders is mn, both divisibilities are equalities: $\#A[m] = m$ and $\#A[n] = n$.

(iii) Let $e = v_\ell(\#A)$ and $\#A = \ell^e m$. If $\ell^k a = 0$, then also $\#A \cdot a = 0$ (Lagrange), so $\gcd(\ell^k, \#A)a = 0$, because by Bezout $\gcd(\ell^k, \#A) = x\ell^k + y\#A$ for some integers x, y. As $\gcd(\ell^k, \#A) = \ell^{\min(k,e)}$ divides ℓ^e, we get $\ell^e a = 0$; so $A[\ell^\infty] = A[\ell^e]$, of order ℓ^e by (ii). A subgroup of ℓ-power order consists of elements killed by a power of ℓ, so lies in $A[\ell^\infty]$; a subgroup of order ℓ^e therefore equals it.

(iv) Apply (ii) repeatedly to the factorisation of $\#A$ into prime powers. For the projector, take $e_\ell = yn$ in (ii) with $m = \ell^{v_\ell(\#A)}$: the proof shows $a \mapsto yna$ is the projection onto $A[m]$, and $yn \equiv 1 \pmod{m}$, $yn \equiv 0 \pmod{n}$.

(v) $\#A \cdot A = 0$ by Lagrange. Let e be the exponent and write $\#A = ce + r$ with $0 \leq r < e$; then $rA = \#A \cdot A - c(eA) = 0$, so $r = 0$ by minimality of e, and $e \mid \#A$. Every prime p dividing $\#A$ is the order of some element a by (i); since $ea = 0$, the order p divides e. Conversely every prime dividing e divides $\#A$, as $e \mid \#A$. For example $A = \mathbb{Z}/2 \oplus \mathbb{Z}/4$ has order 8 and exponent 4. □

In the paper 1.11. Section 1.4 of the paper and the rule built on Definition def:terms use $v_\ell(\#\Phi_q^{\mathrm{geom}})$, the valuation of the order of a finite abelian group; by Proposition 1.10(iii) the ℓ-part of a finite abelian group Φ is $\Phi[\ell^\infty]$, of order $\ell^{v_\ell(\#\Phi)}$. The proof of Lemma lem:tamfactor computes a finite abelian ℓ-group, the torsion $(\mathbb{Z}/\ell^{v_\ell(n)})^2$ of $H^1(I_q, M)$, takes its Frobenius-fixed points and identifies them with "the ℓ-part of the Tamagawa number $c_q(E)$"; the dictionary between the two is the same statement, with Proposition 1.37 for the count of fixed points.

1.2 Direct and semidirect products; dihedral, quaternion and semidihedral groups

This section builds the small groups that the paper names. Proposition prop:ns says that the image of $\bar{\rho}_{E,3}$ is $\mathrm{GL}_2(\mathbb{F}_3)$, the normaliser $N_{ns}(\mathbb{F}_3)$ of a nonsplit Cartan subgroup (order 16) or the normaliser $N_s(\mathbb{F}_3)$ of a split Cartan subgroup (order 8), and that their determinant-one subgroups are $\mathrm{SL}_2(\mathbb{F}_3)$, the quaternion group Q_8 and a cyclic group of order 4. To check such sentences one needs the groups D_4, Q_8 and SD_{16} as abstract groups, together with criteria that recognise them from a few generators and relations; these are Proposition 1.19, Proposition 1.21 and Proposition 1.23, all resting on the elementary Lemma 1.17. Semidirect products also describe the Borel subgroup, the normalisers of Cartan subgroups and, in Chapter 7, the tame Galois group of $\mathbb{Q}_p$.

Proposition 1.12 (Direct products)**.** *The* direct product $G \times H$ *of two groups is the set of pairs with* $(g, h)(g', h') = (gg', hh')$*. If* H *and* K *are normal subgroups of a group* G *with* $H \cap K = 1$ *and*

$HK = G$, then elements of H commute with elements of K, and $(h,k) \mapsto hk$ is an isomorphism $H \times K \to G$.

Proof. For $h \in H$ and $k \in K$ the commutator $hkh^{-1}k^{-1}$ equals $h \cdot (kh^{-1}k^{-1}) \in H$, as H is normal, and equals $(hkh^{-1}) \cdot k^{-1} \in K$, as K is normal; so it lies in $H \cap K = 1$ and $hk = kh$. Hence $(h,k)(h',k') = (hh', kk') \mapsto hh'kk' = hkh'k'$, and the map is a homomorphism. If $hk = 1$, then $h = k^{-1} \in H \cap K$, so $h = k = 1$: the map is injective. It is surjective because $HK = G$. □

Proposition 1.13 (Chinese remainder theorem for groups)**.** *Let $m, n \geq 1$. Then $C_m \times C_n$ is cyclic (and so $\simeq C_{mn}$) if and only if* $\gcd(m,n) = 1$. *Consequently $\mathbb{Z}/n \simeq \prod_{p|n} \mathbb{Z}/p^{v_p(n)}$ as groups, and a finite cyclic group is the direct product of its ℓ-primary parts.*

Proof. Let s, t generate C_m, C_n. The order of (s^a, t^b) is the least common multiple of the orders of s^a and t^b, which divides $\operatorname{lcm}(m,n)$. If $\gcd(m,n) = 1$, the element (s,t) has order $\operatorname{lcm}(m,n) = mn = \#(C_m \times C_n)$ and generates. If $d = \gcd(m,n) > 1$, every element has order dividing $\operatorname{lcm}(m,n) = mn/d < mn$, so no element generates. The decomposition of $\mathbb{Z}/n$ follows by induction on the number of distinct prime factors of n: if $p \mid n$, write $n = p^v n'$ with $v = v_p(n)$ and $p \nmid n'$; then $\gcd(p^v, n') = 1$, so $\mathbb{Z}/n \simeq \mathbb{Z}/p^v \times \mathbb{Z}/n'$, and n' has one prime factor fewer. For instance $\mathbb{Z}/12 \simeq \mathbb{Z}/4 \times \mathbb{Z}/3$, whereas $\mathbb{Z}/2 \times \mathbb{Z}/6$, of order 12, is not cyclic, since $\gcd(2,6) = 2$ and every element is killed by 6. For a cyclic group C of order n, the factor $\mathbb{Z}/p^{v_p(n)}$ is the unique subgroup of order $p^{v_p(n)}$ (Theorem 1.4(i)), which is $C[p^\infty]$ by Proposition 1.10(iii). □

Definition 1.14 (Semidirect products)**.** Let N and H be groups and $\theta\colon H \to \operatorname{Aut}(N)$ a homomorphism. The *semidirect product* $N \rtimes_\theta H$ is the set $N \times H$ with the product

$$(n,h)(n',h') = \big(n\,\theta(h)(n'),\ hh'\big).$$

The product is associative: both $\big((n,h)(n',h')\big)(n'',h'')$ and $(n,h)\big((n',h')(n'',h'')\big)$ equal $\big(n\,\theta(h)(n')\,\theta(hh')(n''),\ hh'h''\big)$, because $\theta(h)(n'\theta(h')(n'')) = \theta(h)(n')\,\theta(h)\theta(h')(n'')$ and θ is a homomorphism. The identity is $(1,1)$ and the inverse of (n,h) is $\big(\theta(h^{-1})(n^{-1}), h^{-1}\big)$. The maps $n \mapsto (n,1)$ and $h \mapsto (1,h)$ identify N and H with subgroups, and

$$(1,h)(n,1)(1,h)^{-1} = \big(\theta(h)(n), h\big)(1,h^{-1}) = \big(\theta(h)(n), 1\big),$$

so that $hnh^{-1} = \theta(h)(n)$, as in convention (C2). The projection $(n,h) \mapsto h$ is a homomorphism with kernel N, so N is normal.

Proposition 1.15 (Recognising semidirect products)**.** *(i) Let $N \trianglelefteq G$ and $H \leq G$ with $N \cap H = 1$ and $NH = G$, and let $\theta(h)(n) = hnh^{-1}$. Then $(n,h) \mapsto nh$ is an isomorphism $N \rtimes_\theta H \to G$.*

(ii) A short exact sequence $1 \to N \to G \xrightarrow{\pi} Q \to 1$ splits*, that is, has a homomorphism $s\colon Q \to G$ with $\pi \circ s = \mathrm{id}$, if and only if $G \simeq N \rtimes_\theta Q$ for some θ, compatibly with the maps from N and to Q.*

(iii) In $N \rtimes_\theta H$ the subgroup H is normal if and only if θ is trivial, in which case $N \rtimes_\theta H = N \times H$.

Proof. (i) $nh \cdot n'h' = n(hn'h^{-1})hh'$, so the map is a homomorphism. If $nh = n'h'$, then $n'^{-1}n = h'h^{-1} \in N \cap H = 1$, so it is injective; it is surjective since $NH = G$. (ii) Given s, put $H = s(Q)$. If $s(x) \in N$, then $x = \pi(s(x)) = 1$, so $N \cap H = 1$; and every g equals $\big(g\,s(\pi(g))^{-1}\big)\,s(\pi(g))$ with the first factor in $\ker\pi = N$, so $NH = G$; now apply (i), noting

$s\colon Q \to H$ is an isomorphism. Conversely $q \mapsto (1,q)$ is a section of $N \rtimes_\theta Q \to Q$. (iii) $(n,1)(1,h)(n,1)^{-1} = (n\,\theta(h)(n^{-1}),h)$ lies in H for all n iff $\theta(h)(n) = n$ for all n. If θ is trivial the product formula is the componentwise one. □

Example 1.16. The following semidirect products occur in this chapter and later in the book.

(a) $D_n = C_n \rtimes C_2$, with C_2 acting by inversion (Definition 1.18).

(b) $\mathrm{GL}_2(F) = \mathrm{SL}_2(F) \rtimes \{\mathrm{diag}(1,d) : d \in F^\times\}$ (Proposition 1.41(ii)), and $\mathrm{B} = \mathrm{U} \rtimes \mathrm{T}$ for the upper triangular group (Proposition 1.46).

(c) $N_s = C_s \rtimes \langle w\rangle$ and $N_{ns} = C_{ns} \rtimes \langle\sigma\rangle$ for the normalisers of Cartan subgroups (Proposition 1.55), and $\mathrm{SL}_2(\mathbb{F}_3) = Q_8 \rtimes C_3$ (Proposition 1.62).

(d) $S_4 = V_4 \rtimes S_3$, with $V_4 = \{1,(12)(34),(13)(24),(14)(23)\}$ normal and S_3 the stabiliser of the point 4: they meet trivially and $\#V_4 \cdot \#S_3 = 24$.

(e) (Foretaste of Chapter 7.) The Galois group of the maximal tamely ramified extension of $\mathbb{Q}_p$ is a semidirect product $\left(\prod_{\ell\neq p}\mathbb{Z}_\ell(1)\right) \rtimes \widehat{\mathbb{Z}}$, in which a Frobenius element acts on the tame inertia group by $\mathrm{Frob}\; t\; \mathrm{Frob}^{-1} = t^p$. The paper uses this in the proofs of Lemma lem:tamfactor and Lemma lem:IV, in the form $\mathrm{Frob}_q\;\sigma\;\mathrm{Frob}_q^{-1} = \sigma^q$ for an element σ of tame inertia. Here Frob_q is an arithmetic Frobenius (it induces $x \mapsto x^q$ on the residue field). The sign convention matters: for the geometric Frobenius Frob_q^{-1} the same relation reads $\mathrm{Frob}_q^{-1}\;\sigma\;\mathrm{Frob}_q = \sigma^{q^{-1}}$, the exponent q^{-1} making sense because q is invertible in each $\mathbb{Z}_\ell$, $\ell \neq q$. A typical consequence is insensitive to the choice: in a linear representation ρ, the matrices $\rho(\sigma)$ and $\rho(\sigma)^q$ are conjugate, so the set of eigenvalues of $\rho(\sigma)$ is stable under $\lambda \mapsto \lambda^q$ (and hence under $\lambda \mapsto \lambda^{q^{-1}}$).

The groups D_n, Q_8 and SD_{16} each consist of the powers of one element a and one coset of them. The following lemma, used three times below, says that such a group is determined by three numbers.

Lemma 1.17 (Normal forms)**.** *Let $n \geq 1$, k and c be integers with $k^2 \equiv 1 \pmod n$ and $kc \equiv c \pmod n$. Let G be a group with elements a, b such that $a^n = 1$, $bab^{-1} = a^k$, $b^2 = a^c$, and such that the $2n$ elements $a^m b^e$ $(0 \leq m < n,\ e \in \{0,1\})$ are distinct and exhaust G. Then the product in G is given by*

$$a^m b^e \cdot a^{m'} b^{e'} = \begin{cases} a^{m+k^e m'} b^{e+e'} & \text{if } e+e' \leq 1, \\ a^{m+km'+c} & \text{if } e = e' = 1. \end{cases}$$

In particular, if G', a', b' satisfy the same hypotheses with the same (n,k,c), then $a^m b^e \mapsto a'^m b'^e$ is an isomorphism $G \to G'$.

Proof. From $bab^{-1} = a^k$ we get $ba^{m'}b^{-1} = a^{km'}$, so $b^e a^{m'} = a^{k^e m'} b^e$, and $a^m b^e a^{m'} b^{e'} = a^{m+k^e m'} b^e b^{e'}$; when $e = e' = 1$, $b^e b^{e'} = b^2 = a^c$. Since exponents of a only matter modulo n, the right-hand side is computed from (n,k,c) alone, and the bijection $a^m b^e \mapsto a'^m b'^e$ respects products. (The congruences on k and c are forced: $a = b^2 a b^{-2} = a^{k^2}$ and b commutes with $b^2 = a^c$; they are not used in the proof.) □

Definition 1.18 (Dihedral groups)**.** For $n \geq 2$ the *dihedral group* of order $2n$ is $D_n = \mathbb{Z}/n \rtimes_\theta \mathbb{Z}/2$, with $\theta(1)$ the inversion $x \mapsto -x$. Writing $r = (1,0)$ and $s = (0,1)$, we have $r^n = s^2 = 1$ and

$srs^{-1} = r^{-1}$, and $D_n = \{r^m s^e\}$. For $n \geq 3$, D_n is the group of symmetries of a regular n-gon in the plane, r being the rotation by $2\pi/n$ and s a reflection (the familiar picture from Riley-Hobson-Bence).

Proposition 1.19. *(i) (Recognition) Let G be a group of order $2n$ generated by an element r of order n and an element s of order 2 with $srs^{-1} = r^{-1}$. Then $G \simeq D_n$, with $r \mapsto (1,0)$ and $s \mapsto (0,1)$.*

(ii) Every element of D_n outside $\langle r \rangle$ has order 2.

(iii) For $n \geq 3$ the centre of D_n is trivial if n is odd and is $\{1, r^{n/2}\}$ if n is even.

(iv) $D_2 \simeq V_4$, $D_3 \simeq S_3$ and $D_6 \simeq C_2 \times S_3$.

(v) D_4 has five elements of order 2 (namely r^2, s, rs, r^2s, r^3s) and two of order 4 (namely r, r^3).

Proof. (i) Since $srs^{-1} = r^{-1}$, both generators normalise $\langle r \rangle$, which is therefore normal, and $\langle r \rangle \langle s \rangle$ is a subgroup (Theorem 1.6(ii)) containing r and s, hence equal to G. Its order is computed from the second isomorphism theorem: with $N = \langle r \rangle$ and $H = \langle s \rangle$, $\#(HN) = \#N \cdot \#(HN/N) = \#N \cdot \#(H/(H \cap N)) = \#N \, \#H/\#(H \cap N)$, that is $n \cdot 2/\#(\langle r \rangle \cap \langle s \rangle)$. This must be $\#G = 2n$, so $\langle r \rangle \cap \langle s \rangle = 1$ and $s \notin \langle r \rangle$. Hence $G = \langle r \rangle \cup \langle r \rangle s$, the $2n$ elements $r^m s^e$ ($0 \leq m < n$, $e \in \{0,1\}$) exhaust G, and as there are $2n$ of them in a group of order $2n$ they are distinct. Apply Lemma 1.17 with $(n,k,c) = (n,-1,0)$ to G and to D_n. (ii) $(r^m s)^2 = r^m (s r^m s^{-1}) = r^m r^{-m} = 1$, and $r^m s \neq 1$. (iii) r^m commutes with s iff $r^m = r^{-m}$ iff $n \mid 2m$, which gives $m = 0$, or $m = n/2$ when n is even; r^m commutes with r. An element $r^m s$ is not central: $r(r^m s) r^{-1} = r^{m+2} s \neq r^m s$ as $n \geq 3$. (iv) D_2 has order 4 and all its nontrivial elements have order 2 by (ii) and $r^2 = 1$; so it is V_4 (it is abelian, being generated by two commuting involutions, as $srs^{-1} = r^{-1} = r$). In S_3, $r = (123)$ and $s = (12)$ satisfy $srs^{-1} = (213) = r^{-1}$, so (i) gives $S_3 \simeq D_3$. In D_6, the centre $Z = \{1, r^3\}$ and the subgroup $K = \langle r^2, s \rangle = \{1, r^2, r^4, s, r^2 s, r^4 s\}$ are normal (K has index 2), $Z \cap K = 1$ and $ZK = D_6$; so $D_6 \simeq C_2 \times K$ by Proposition 1.12, and $K \simeq D_3 \simeq S_3$ by (i). (v) follows from (ii) and the orders of the powers of r. □

Definition 1.20 (The quaternion group)**.** Let $\mathbf{i} = \sqrt{-1} \in \mathbb{C}$. In $\mathrm{GL}_2(\mathbb{C})$ put

$$1 = I, \qquad i = \begin{pmatrix} \mathbf{i} & 0 \\ 0 & -\mathbf{i} \end{pmatrix}, \qquad j = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad k = ij = \begin{pmatrix} 0 & \mathbf{i} \\ \mathbf{i} & 0 \end{pmatrix}.$$

The *quaternion group* is $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$. Direct multiplication gives $i^2 = j^2 = k^2 = ijk = -1$, $ji = -k$, and $jij^{-1} = -i = i^{-1}$; so Q_8 is a subgroup of order 8, and $Q_8 = \{i^m j^e : 0 \leq m < 4,\ e \in \{0,1\}\}$ with $i^4 = 1$, $jij^{-1} = i^{-1}$, $j^2 = i^2$. (These are Hamilton's quaternion units.)

Proposition 1.21. *(i) -1 is the unique element of order 2 of Q_8, and the six elements $\pm i, \pm j, \pm k$ have order 4.*

(ii) $Z(Q_8) = [Q_8, Q_8] = \{\pm 1\}$, and $Q_8/\{\pm 1\} \simeq V_4$.

(iii) Every subgroup of Q_8 is normal, and every nontrivial subgroup contains -1. In particular Q_8 is not a semidirect product of two nontrivial subgroups.

(iv) $Q_8 \not\simeq D_4$.

(v) (Recognition) A non-abelian group of order 8 *with a unique element of order* 2 *is isomorphic to* Q_8.

Proof. (i) Each of $\pm i, \pm j, \pm k$ squares to -1. (ii) $-1 = -I$ is central; i and j do not commute ($ji = -ij$), and similarly no element other than ± 1 is central (each of $\pm i$, $\pm j$, $\pm k$ anticommutes with one of the others). The commutator $iji^{-1}j^{-1} = ij(-i)(-j) = (ij)^2 = k^2 = -1$, so $-1 \in [Q_8, Q_8]$. The quotient $Q_8/\{\pm 1\}$ has order 4 and every element squares to 1 there, since $x^2 \in \{\pm 1\}$; so it is V_4, which is abelian, and $[Q_8, Q_8] \leq \{\pm 1\}$. (iii) Every $x \neq 1$ satisfies $x = -1$ or $x^2 = -1$, so a nontrivial subgroup contains -1. Subgroups of order 1, 8 are normal, $\{\pm 1\}$ is central, and subgroups of order 4 have index 2 (Lemma 1.7). Two nontrivial subgroups meet in $\{\pm 1\}$ at least, so Q_8 is not $N \rtimes H$ with $N, H \neq 1$. (iv) D_4 has five elements of order 2 (Proposition 1.19(v)), Q_8 one. (v) Let G be non-abelian of order 8 with unique involution z. No element has order 8 (G would be cyclic), so every element other than 1, z has order 4. Choose a of order 4; then a^2 has order 2, so $a^2 = z$. Choose $b \notin \langle a \rangle$; it has order 4 and $b^2 = z = a^2$. The subgroup $\langle a \rangle$ has index 2, hence is normal, so bab^{-1} is an element of order 4 of $\langle a \rangle$, that is a or a^{-1}. If $bab^{-1} = a$, then $G = \langle a \rangle \cup \langle a \rangle b$ is abelian, a contradiction. So $bab^{-1} = a^{-1}$, and Lemma 1.17 with $(n, k, c) = (4, -1, 2)$, applied to (G, a, b) and (Q_8, i, j), gives $G \simeq Q_8$. □

Definition 1.22 (The semidihedral group)**.** The *semidihedral group* of order 16 is $SD_{16} = \mathbb{Z}/8 \rtimes_\theta \mathbb{Z}/2$ with $\theta(1)$ the automorphism $x \mapsto 3x$ (of order 2, as $9 \equiv 1 \pmod 8$). Writing $a = (1, 0)$, $x = (0, 1)$, we have $a^8 = x^2 = 1$, $xax^{-1} = a^3$ and $SD_{16} = \{a^m x^e\}$.

Proposition 1.23. *(i)* $(a^m x)^2 = a^{4m}$*; so* $a^m x$ *has order* 2 *for* m *even and order* 4 *for* m *odd.*

(ii) SD_{16} *has* 1, 5, 6, 4 *elements of orders* 1, 2, 4, 8, *and* $Z(SD_{16}) = \{1, a^4\}$.

(iii) The subgroups of index 2 *of* SD_{16} *are exactly three:* $\langle a \rangle \simeq C_8$, $\langle a^2, x \rangle \simeq D_4$ *and* $\langle a^2, ax \rangle \simeq Q_8$.

(iv) (Recognition) A group of order 16 *generated by an element* a *of order* 8 *and an element* x *of order* 2 *with* $xax^{-1} = a^3$ *is isomorphic to* SD_{16}.

Proof. (i) $(a^m x)^2 = a^m(xa^m x^{-1}) = a^m a^{3m} = a^{4m}$, which is 1 for m even and $a^4 \neq 1$ for m odd. (ii) In $\langle a \rangle$ there are $1, 1, 2, 4$ elements of orders $1, 2, 4, 8$; in the coset $\langle a \rangle x$ there are four of order 2 and four of order 4 by (i). An element a^m is central iff $xa^m x^{-1} = a^{3m}$ equals a^m, iff $a^{2m} = 1$, iff $m \in \{0, 4\}$; no $a^m x$ is central, since $a(a^m x)a^{-1} = a^{m+1}a^{-3}x = a^{m-2}x$. (iii) A subgroup K of index 2 is normal with quotient of order 2 (Lemma 1.7), so it contains every square: the image of g^2 in $SD_{16}/K \simeq C_2$ is the square of an element of C_2, hence trivial. The squares include a^2, so $K \supseteq \langle a^2 \rangle$. The subgroup $\langle a^2 \rangle$ of order 4 is normal ($xa^2x^{-1} = a^6$), and $SD_{16}/\langle a^2 \rangle$ has order 4 and is generated by the images of a and x, which commute ($xax^{-1}a^{-1} = a^2$) and have order dividing 2; so it is V_4, which has exactly three subgroups of order 2. By the correspondence theorem (Theorem 1.6(iv)) there are exactly three subgroups of index 2, namely $\langle a \rangle$, $\langle a^2, x \rangle$ and $\langle a^2, ax \rangle$. The second is dihedral by Proposition 1.19(i): it has order 8, a^2 has order 4, x has order 2, and $xa^2x^{-1} = a^6 = a^{-2}$. The third consists of a^{2m} and $a^{2m+1}x$; by (i) the latter have order 4, so a^4 is its unique involution, and it is non-abelian ($(ax)a^2(ax)^{-1} = a \cdot a^6 \cdot a^{-1} = a^{-2} \neq a^2$); so it is Q_8 by Proposition 1.21(v). (iv) As in Proposition 1.19(i), $\langle a \rangle$ is normal, $G = \langle a \rangle \langle x \rangle$, and the order 16 forces $x \notin \langle a \rangle$; apply Lemma 1.17 with $(n, k, c) = (8, 3, 0)$. □

Remark 1.24. There are four non-abelian groups of order 16 with a cyclic subgroup $\langle a \rangle$ of order 8 and an element $x \notin \langle a \rangle$ with $xax^{-1} = a^k$, $x^2 = a^c$: the dihedral group D_8 ($k = -1$, $c = 0$), SD_{16}

($k = 3$, $c = 0$), the generalised quaternion group Q_{16} ($k = -1$, $c = 4$) and the modular group M_{16} ($k = 5$, $c = 0$). In each case $(a^m x)^2 = a^{m(1+k)+c}$, and counting as in Proposition 1.23 gives the numbers of elements of orders $1, 2, 4, 8$:

group	order 1	order 2	order 4	order 8
D_8	1	9	2	4
SD_{16}	1	5	6	4
Q_{16}	1	1	10	4
M_{16}	1	3	4	8

So these four groups are pairwise non-isomorphic, and a group of order 16 is recognised as SD_{16} by its element orders among them. We use only SD_{16}, through Proposition 1.23(iv).

Theorem 1.25 (Groups of order 8)**.** *Every group of order* 8 *is isomorphic to exactly one of* C_8, $C_4 \times C_2$, C_2^3, D_4, Q_8.

Proof. If G is abelian, Theorem 1.35 (proved in Section 1.4, independently of this theorem) writes G as a sum of cyclic groups $\mathbb{Z}/2^{e_i}$ with $\sum_i e_i = 3$; the multisets of exponents are $\{3\}$, $\{2, 1\}$, $\{1, 1, 1\}$, giving exactly the first three groups. By Proposition 1.37, $\#G[2] = 2^{\#\{i\}}$ is 2, 4, 8 for them, so they are pairwise non-isomorphic. Let G be non-abelian. If every element had order at most 2, then G would be abelian ($ab = (ab)^{-1} = b^{-1}a^{-1} = ba$); and no element has order 8. So there is r of order 4, and $\langle r\rangle$ has index 2, hence is normal. Let $s \notin \langle r\rangle$. Then $srs^{-1} \in \{r, r^{-1}\}$ (the elements of order 4 of $\langle r\rangle$), and $srs^{-1} = r$ would make $G = \langle r, s\rangle$ abelian; so $srs^{-1} = r^{-1}$. Next $s^2 \in \langle r\rangle$ (the quotient has order 2) and s^2 commutes with s, so $s^2 = s(s^2)s^{-1}$, which is $(s^2)^{-1}$ if $s^2 \in \{r, r^{-1}\}$; that would force $r^2 = 1$. So $s^2 \in \{1, r^2\}$. If $s^2 = 1$, then $G \simeq D_4$ by Proposition 1.19(i); if $s^2 = r^2$, then $G \simeq Q_8$ by Lemma 1.17 with $(n, k, c) = (4, -1, 2)$. The five groups are pairwise non-isomorphic: the three abelian ones are distinguished by $\#G[2]$, and $D_4 \not\simeq Q_8$ by Proposition 1.21(iv). □

In the paper 1.26. The proof of Proposition prop:ns names an isomorphism type, "the quaternion group Q_8", and Section sec:open of the paper calls the case of image $N_s(\mathbb{F}_3)$ the dihedral case. In Section 1.6 these types are identified by the recognition criteria: $N_s(\mathbb{F}_3) \simeq D_4$ by Proposition 1.19(i), the determinant-one subgroup of $N_{ns}(\mathbb{F}_3)$ is Q_8 by Proposition 1.21(v), and $N_{ns}(\mathbb{F}_3) \simeq SD_{16}$ by Proposition 1.23(iv). Theorem 1.25 is context; nothing in the paper depends on it.

1.3 Group actions, orbit-stabiliser, p-groups and the Sylow theorems

Groups enter the paper through their actions: the Galois group acts on the torsion points of E, the decomposition and inertia groups are stabilisers (Chapter 6, Chapter 7), and the four roots of the 3-division polynomial correspond to the four lines of $E[3] \simeq \mathbb{F}_3^2$, permuted by the image of $\bar{\rho}_{E,3}$. The last sentence of Proposition prop:ns, on the factorisation of that polynomial, is a statement about the orbits of a subgroup of $\mathrm{GL}_2(\mathbb{F}_3)$ on these four lines, and Proposition 1.29 is the tool that compares the orbits of a group and of a subgroup of index 2. The Sylow theorems are used to locate the 2-subgroups and the 3-subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$ in Section 1.6.

Definition 1.27 (Group actions)**.** A (left) *action* of a group G on a set X is a map $G \times X \to X$, $(g, x) \mapsto gx$, with $1x = x$ and $g(hx) = (gh)x$. Equivalently, it is a homomorphism $G \to \mathrm{Sym}(X)$ to the group of bijections of X (the *permutation representation*). Its kernel is the kernel of this homomorphism; the action is *faithful* if the kernel is trivial. The *orbit* of x is $Gx = \{gx : g \in G\}$, the *stabiliser* of x is $G_x = \{g : gx = x\}$, a subgroup, and the *fixed set* is $X^G = \{x : gx = x \ \forall g\}$; for one element g we write X^g for its fixed points. The action is *transitive* if there is one orbit. An action restricts to every subgroup $H \leq G$. Examples: G acts on G/H by $g \cdot xH = gxH$; G acts on itself and on the set of its subgroups by conjugation, with stabilisers $C_G(g)$ and $N_G(H)$; $\mathrm{GL}_2(F)$ acts on F^2, on $F^2 \setminus \{0\}$ and on the set $\mathbb{P}^1(F)$ of lines (Proposition 1.44).

Theorem 1.28 (Orbit-stabiliser)**.** *Let G act on X and let $x \in X$. Then $gG_x \mapsto gx$ is a well-defined bijection $G/G_x \to Gx$, compatible with the actions of G; so $\#Gx = [G : G_x]$ when G is finite. Moreover $G_{gx} = gG_xg^{-1}$. The orbits partition X, and if X is finite and $x_1, \dots, x_r$ are representatives of the orbits, then $\#X = \sum_{i=1}^{r} [G : G_{x_i}]$.*

Proof. $gx = hx$ iff $h^{-1}g \in G_x$ iff $gG_x = hG_x$: so the map is well defined and injective; it is surjective by definition of Gx, and $h \cdot gG_x = hgG_x \mapsto hgx$. If $h \in G_x$, then $(ghg^{-1})(gx) = gx$, so $gG_xg^{-1} \subseteq G_{gx}$; applying this to g^{-1} and gx gives the reverse inclusion. The relation "$y \in Gx$" is an equivalence relation ($x = 1x$; $y = gx \Rightarrow x = g^{-1}y$; $z = hy$, $y = gx \Rightarrow z = hgx$), whose classes are the orbits. Summing the orbit sizes gives the last formula. □

A first example, which recurs throughout the chapter: $\mathrm{GL}_2(\mathbb{F}_3)$, of order 48 (Proposition 1.43), acts transitively on the four lines of $\mathbb{F}_3^2$ (Proposition 1.44), and the stabiliser of $\infty = [e_1]$ is the upper triangular group $\mathrm{B}(\mathbb{F}_3)$, of order $3 \cdot 2 \cdot 2 = 12$ (the entry b is arbitrary and $a, d \in \{\pm 1\}$). Orbit-stabiliser gives $48/12 = 4$ lines, as it must. In the other direction, the formula is often used to compute a stabiliser from an orbit: the stabiliser of the pair $\{\infty, 0\}$ has order $48/6 = 8$, since $\mathrm{GL}_2(\mathbb{F}_3)$ is transitive on the six 2-element sets of lines (Proposition 1.44(v)); it is $N_s(\mathbb{F}_3)$ (Proposition 1.63(ii)).

Proposition 1.29 (Orbits of a subgroup)**.** *Let G act transitively on a finite set X, let $x \in X$ and let $H \leq G$.*

(i) The map $HgG_x \mapsto H \cdot gx$ is a bijection from the double cosets $H\backslash G/G_x$ to the H-orbits on X. In particular H is transitive on X if and only if $G = HG_x$.

(ii) If $H \trianglelefteq G$, then G permutes the H-orbits transitively; all H-orbits have the same size, which divides $\#X$.

(iii) If $[G : H] = 2$, then either H is transitive on X, or X is the union of exactly two H-orbits, each of size $\#X/2$, and every element of $G \setminus H$ interchanges them.

Proof. (i) Every element of X is gx for some g. Now $Hgx = Hg'x$ iff $g'x = hgx$ for some $h \in H$ iff $g^{-1}h^{-1}g' \in G_x$ for some h iff $g' \in HgG_x$. So the map is well defined and injective. It is surjective because every H-orbit is Hy for some $y \in X$, and $y = gx$ for some g by transitivity of G, so Hy is the image of HgG_x. There is one H-orbit iff there is one double coset, iff $HG_x = G$ (the double coset of 1 is HG_x, and it is all of G exactly when there are no others). (ii) For $g \in G$ and $y \in X$, $g(Hy) = gHg^{-1}gy = H(gy)$; so g maps H-orbits to H-orbits, bijectively (with inverse g^{-1}). Given two orbits Hy, Hy', choose g with $gy = y'$ (transitivity of G); then $g(Hy) = Hy'$. Hence all orbits have the size of one of them, say s, and $\#X = s \cdot$ (number of orbits). (iii) H is normal by Lemma 1.7. The group G acts transitively on the set Ω of H-orbits by (ii), and H

acts trivially on Ω; so the action factors through G/H, of order 2, and $\#\Omega \in \{1,2\}$. If $\#\Omega = 2$, each orbit has size $\#X/2$ by (ii); the stabiliser of one H-orbit is a subgroup containing H and different from G (the action on Ω is transitive), hence equal to H, so every element of $G \setminus H$ moves it to the other one. □

Lemma 1.30 (Orbit counting)**.** *Let a finite group G act on a finite set X. The number of orbits is* $\dfrac{1}{\#G}\displaystyle\sum_{g\in G} \#X^g$.

Proof. Count the pairs (g,x) with $gx = x$ in two ways: $\sum_g \#X^g = \sum_x \#G_x$. By Theorem 1.28, $\#G_x = \#G/\#Gx$, so the elements of one orbit O contribute $\#O \cdot \#G/\#O = \#G$, and the sum is $\#G$ times the number of orbits. □

For example, let $C_4 = \langle J\rangle = \{\pm I, \pm J\} \leq \mathrm{GL}_2(\mathbb{F}_3)$ act on the four lines. The scalars $\pm I$ fix all four lines; $\pm J$ fix none, since their characteristic polynomial X^2+1 has no root in $\mathbb{F}_3$, so they have no eigenvector over $\mathbb{F}_3$. The lemma gives $(4+4+0+0)/4 = 2$ orbits. Since the scalars act trivially, the action factors through $C_4/\{\pm I\}$, of order 2, so every orbit has size 1 or 2; there is no fixed line, so the two orbits both have size 2, recovering Proposition 1.63(iv) without listing the action.

Theorem 1.31 (Class equation; p-groups)**.** *Let G be finite. Then $\#G = \#Z(G) + \sum_i [G : C_G(g_i)]$, the sum over representatives g_i of the conjugacy classes with more than one element. Let p be a prime.*

(i) If a finite p-group P acts on a finite set X, then $\#X \equiv \#X^P \pmod p$.

(ii) A nontrivial finite p-group has nontrivial centre.

(iii) A group of order p^2 is abelian.

(iv) A group of order p^n has a normal subgroup of order p^k for every $0 \leq k \leq n$, and every subgroup of index p in a finite p-group is normal.

Proof. The class equation is Theorem 1.28 for the conjugation action: the fixed points are the central elements, and the class of g_i has $[G : C_G(g_i)]$ elements (Proposition 1.9). (i) Each orbit has size $[P : P_x]$, a power of p, which is 1 exactly for the fixed points; so $\#X - \#X^P$ is a sum of positive powers of p. (ii) Apply (i) to the conjugation action of P on itself: $\#Z(P) \equiv \#P \equiv 0 \pmod p$, and $\#Z(P) \geq 1$, so $\#Z(P) \geq p$. (iii) First, if $G/Z(G)$ is cyclic, generated by the class of g, then every element is $g^m z$ with z central, and any two such elements commute; so G is abelian. If $\#G = p^2$, then $\#Z(G) \in \{p, p^2\}$ by (ii); if it were p, then $G/Z(G)$ would have order p, hence be cyclic, and G would be abelian, so $Z(G) = G$, a contradiction. (iv) Induction on n. For $k = 0$ the trivial subgroup does, which settles $n = 0$. For $n \geq 1$, $Z(G)$ is a nontrivial abelian p-group by (ii), so it has an element z of order p (Proposition 1.10(i)), and $\langle z\rangle$ is normal, being central. For $k \geq 1$, by induction $G/\langle z\rangle$ (order p^{n-1}) has a normal subgroup of order p^{k-1}, whose preimage is normal of order p^k (Theorem 1.6(iv)). Finally let $H \leq P$ have index p. Then H acts on P/H by left multiplication; by (i), the number of fixed cosets is $\equiv p \equiv 0 \pmod p$, and the coset H is fixed, so there are at least p fixed cosets, that is, all of them. So $hgH = gH$ for all $h \in H$, $g \in P$, that is, $g^{-1}Hg \subseteq H$ for all g, and H is normal. □

Theorem 1.32 (Cauchy)**.** *If a prime p divides the order of a finite group G, then G has an element of order p.*

Proof. (McKay's argument.) Let $X = \{(g_1, \dots, g_p) \in G^p : g_1 g_2 \cdots g_p = 1\}$. The first $p-1$ entries may be chosen freely and determine the last, so $\#X = \#G^{p-1} \equiv 0 \pmod p$. The cyclic group C_p acts on X by rotation $(g_1, \dots, g_p) \mapsto (g_2, \dots, g_p, g_1)$; this preserves X, since $g_2 \cdots g_p g_1 = g_1^{-1}(g_1 \cdots g_p) g_1 = 1$. The fixed points are the constant tuples $(g, \dots, g)$ with $g^p = 1$. By Theorem 1.31(i) their number is $\equiv \#X \equiv 0 \pmod p$; it is at least 1 (take $g = 1$), hence at least p. So some $g \neq 1$ has $g^p = 1$, and it has order p. □

Theorem 1.33 (Sylow)**.** *Let G be a finite group of order $p^a m$ with p prime and $p \nmid m$. A subgroup of order p^a is a* Sylow p-subgroup.

(i) G has a Sylow p-subgroup.

(ii) Every p-subgroup of G is contained in a Sylow p-subgroup, and any two Sylow p-subgroups are conjugate.

(iii) The number n_p of Sylow p-subgroups equals $[G : N_G(P)]$ for any Sylow p-subgroup P; it divides m, and $n_p \equiv 1 \pmod p$.

(iv) A Sylow p-subgroup P is normal if and only if $n_p = 1$; a normal Sylow p-subgroup contains every element of p-power order of G.

Proof. (i) (Wielandt's argument.) First, $\binom{p^a m}{p^a} \equiv m \pmod p$: in $\mathbb{F}_p[X]$ we have $(1+X)^p = 1 + X^p$, since p divides $\binom{p}{i}$ for $0 < i < p$; hence $(1+X)^{p^a m} = (1 + X^{p^a})^m$, and comparing the coefficients of X^{p^a} gives the claim. Let Ω be the set of subsets of G with p^a elements, on which G acts by left multiplication, $gS = \{gs : s \in S\}$. As $\#\Omega = \binom{p^a m}{p^a} \equiv m \not\equiv 0 \pmod p$ and $\#\Omega$ is the sum of the orbit sizes, some orbit GS has size prime to p. Its stabiliser $G_S = \{g : gS = S\}$ has order $\#G/\#GS = p^a m/\#GS$ (Theorem 1.28), and since $\#GS$ is prime to p, all of p^a survives: $p^a \mid \#G_S$. On the other hand, fix $s \in S$; for $g \in G_S$ we have $gs \in gS = S$, so the right coset $G_S s$ lies in S, and $\#G_S = \#G_S s \leq \#S = p^a$. Hence $\#G_S = p^a$, and G_S is a Sylow p-subgroup. (ii) Let Q be a p-subgroup and P a Sylow p-subgroup. Then Q acts on G/P by left multiplication, and $\#(G/P) = m \not\equiv 0 \pmod p$; by Theorem 1.31(i) there is a fixed coset gP. Then $QgP = gP$, so $g^{-1}Qg \subseteq P$ and $Q \subseteq gPg^{-1}$, which is a Sylow p-subgroup. If Q is itself Sylow, comparing orders gives $Q = gPg^{-1}$. (iii) By (ii), G acts transitively by conjugation on the set Syl_p of Sylow p-subgroups, with stabiliser $N_G(P)$; so $n_p = [G : N_G(P)]$, which divides $[G : P] = m$ since $P \leq N_G(P)$. Let P act on Syl_p by conjugation. If Q is fixed, then $P \leq N_G(Q)$, and P, Q are Sylow p-subgroups of $N_G(Q)$, in which Q is normal; by (ii) applied to the group $N_G(Q)$ they are conjugate in $N_G(Q)$, and Q is normal there, so $P = Q$. So P has exactly one fixed point, and $n_p \equiv 1 \pmod p$ by Theorem 1.31(i). (iv) The first statement is $n_p = [G : N_G(P)]$. If P is normal and g has p-power order, then $\langle g \rangle$ lies in some Sylow p-subgroup by (ii), which is P. □

Example 1.34. (a) A group of order 15 is cyclic: n_3 divides 5 and is $\equiv 1 \pmod 3$, so $n_3 = 1$; n_5 divides 3 and is $\equiv 1 \pmod 5$, so $n_5 = 1$. The two Sylow subgroups $P_3 \simeq C_3$, $P_5 \simeq C_5$ are normal, meet trivially and $\#P_3P_5 = 15$; so $G \simeq C_3 \times C_5 \simeq C_{15}$ by Proposition 1.12 and Proposition 1.13.

(b) In S_4 (order $24 = 2^3 \cdot 3$): the eight 3-cycles lie in four subgroups of order 3, two in each, so $n_3 = 4$. The group S_4 permutes transitively the three partitions $\{\{1,2\},\{3,4\}\}$, $\{\{1,3\},\{2,4\}\}$, $\{\{1,4\},\{2,3\}\}$ of $\{1,2,3,4\}$ into two pairs, so each stabiliser has order $24/3 = 8$ by Theorem 1.28; it is a Sylow 2-subgroup. The stabiliser of $\{\{1,2\},\{3,4\}\}$ contains (1324), of order 4, and (12), with $(12)(1324)(12) = (1423) = (1324)^{-1}$, so it is dihedral by Proposition 1.19(i). This Sylow

2-subgroup is not normal (it contains (12) but not its conjugate (13), which sends $\{1,2\}$ to $\{3,2\}$), so $n_2 \neq 1$; as $n_2 \mid 3$, $n_2 = 3$, and the three stabilisers are the three Sylow 2-subgroups.

(c) In $\mathrm{GL}_2(\mathbb{F}_3)$ (order $48 = 2^4 \cdot 3$): $n_3 = 4$, the four subgroups U_L of Proposition 1.48(v), one for each line L of $\mathbb{F}_3^2$; and $n_2 = 3$, the three conjugates of $N_{ns}(\mathbb{F}_3)$ (Proposition 1.64(iii)).

(d) In $\mathrm{SL}_2(\mathbb{F}_3)$ (order 24): $n_2 = 1$, the Sylow 2-subgroup being Q_8 (Proposition 1.62(ii)), and $n_3 = 4$.

1.4 Finite abelian groups

The paper's local invariants are orders of finite abelian groups and their ℓ-parts: the geometric component groups Φ_q^{geom}, of the shapes $\mathbb{Z}/n$, $\mathbb{Z}/2$, $\mathbb{Z}/3$, $(\mathbb{Z}/2)^2$, $\mathbb{Z}/4$ (Chapter 10), the Tamagawa numbers, and the torsion subgroup $H^1(I_q, M)_{\mathrm{tor}} \simeq (\mathbb{Z}/\ell^{v_\ell(n)})^2$ in the proof of Lemma lem:tamfactor, whose Frobenius-fixed points are counted there. This section proves the structure theorem and the counting rule $\#A[n] = \#A/nA$ used for that count, and shows that the multiplicative group of a finite field is cyclic, which Lemma lem:h0 uses for $\mathbb{F}_\ell^\times$. Groups are written additively; $A[n] = \{a \in A : na = 0\}$.

Theorem 1.35 (Structure of finite abelian groups)**.** *Every finite abelian group A is isomorphic to $\bigoplus_{i=1}^{s} \mathbb{Z}/\ell_i^{e_i}$ for primes ℓ_i and integers $e_i \geq 1$, and the multiset of prime powers $\ell_i^{e_i}$ (the* elementary divisors*) is determined by A. Equivalently, $A \simeq \mathbb{Z}/d_1 \oplus \cdots \oplus \mathbb{Z}/d_r$ with $1 < d_1 \mid d_2 \mid \cdots \mid d_r$, and the* invariant factors *d_i are determined by A. For each prime ℓ, the numbers $\#A[\ell^k]$, $k \geq 1$, determine $A[\ell^\infty]$ up to isomorphism: the number of i with $\ell_i = \ell$ and $e_i \geq k$ is $\log_\ell(\#A[\ell^k]/\#A[\ell^{k-1}])$.*

Proof. By Proposition 1.10(iv), $A = \bigoplus_\ell A[\ell^\infty]$, so it suffices to treat a finite abelian ℓ-group A.

Existence. We show by induction on $\#A$: if $a \in A$ has maximal order ℓ^e, then $A = \langle a \rangle \oplus B$ for some subgroup B; applying this again to B gives the decomposition. If $A = \langle a \rangle$, take $B = 0$. Otherwise choose $b \notin \langle a \rangle$ of least possible order. Then ℓb has smaller order, so $\ell b \in \langle a \rangle$, say $\ell b = ta$. Since $\ell^{e-1}(ta) = \ell^e b = 0$ (the order of b is at most ℓ^e), the element ta is not a generator of $\langle a \rangle$, so $\ell \mid t$, say $t = \ell t'$. Put $c = b - t'a$. Then $\ell c = 0$ and $c \notin \langle a \rangle$, so $C = \langle c \rangle$ has order ℓ and $C \cap \langle a \rangle = 0$. In $\bar{A} = A/C$ the image $\bar{a}$ has order ℓ^e (if $\ell^{e-1}a \in C$, then $\ell^{e-1}a \in C \cap \langle a \rangle = 0$), and this is the maximal order in $\bar{A}$, as orders can only drop in a quotient. By induction $\bar{A} = \langle \bar{a} \rangle \oplus \bar{B}$; let B be the preimage of $\bar{B}$, which contains C. If $ma \in B$, then $m\bar{a} \in \langle \bar{a} \rangle \cap \bar{B} = 0$, so $ma \in C \cap \langle a \rangle = 0$; thus $\langle a \rangle \cap B = 0$. For $x \in A$ write $\bar{x} = m\bar{a} + \bar{y}$ with $y \in B$; then $x - ma - y \in C \subseteq B$, so $x \in \langle a \rangle + B$. Hence $A = \langle a \rangle \oplus B$.

Uniqueness. If $A \simeq \bigoplus_i \mathbb{Z}/\ell^{e_i}$, then $A[\ell^k] \simeq \bigoplus_i (\mathbb{Z}/\ell^{e_i})[\ell^k]$, and $(\mathbb{Z}/\ell^e)[\ell^k]$ has order $\ell^{\min(k,e)}$ (Theorem 1.4(i)). So $\#A[\ell^k] = \ell^{\sum_i \min(k,e_i)}$, and, since $\min(k,e_i) - \min(k-1,e_i)$ is 1 if $e_i \geq k$ and 0 otherwise, $\#A[\ell^k]/\#A[\ell^{k-1}] = \ell^{\#\{i : e_i \geq k\}}$. The left side is defined in terms of A alone (an isomorphism $A \to A'$ maps $A[\ell^k]$ onto $A'[\ell^k]$), so the numbers $N_k = \#\{i : e_i \geq k\}$, $k \geq 1$, are the same for any two decompositions. They determine the multiset $\{e_i\}$: exactly $N_k - N_{k+1}$ of the exponents equal k.

Invariant factors. Given the elementary divisors, list for each ℓ the exponents in decreasing order $e_{\ell,1} \geq e_{\ell,2} \geq \cdots$ (padded with zeros), and put $d_r = \prod_\ell \ell^{e_{\ell,1}}$, $d_{r-1} = \prod_\ell \ell^{e_{\ell,2}}$, and so on. By Proposition 1.13, $\mathbb{Z}/d_j \simeq \bigoplus_\ell \mathbb{Z}/\ell^{e_{\ell,r+1-j}}$, so $A \simeq \bigoplus_j \mathbb{Z}/d_j$, with $d_1 \mid \cdots \mid d_r$. Conversely the elementary divisors of $\bigoplus_j \mathbb{Z}/d_j$ are the prime powers exactly dividing the d_j, so the d_j are determined by the elementary divisors, hence by A. □

For example, $A = \mathbb{Z}/2 \oplus \mathbb{Z}/4 \oplus \mathbb{Z}/3 \oplus \mathbb{Z}/9$ has elementary divisors $2, 4, 3, 9$. Listing exponents in decreasing order gives $(2,1)$ for $\ell = 2$ and $(2,1)$ for $\ell = 3$, so $d_2 = 4 \cdot 9 = 36$, $d_1 = 2 \cdot 3 = 6$, and

$A \simeq \mathbb{Z}/6 \oplus \mathbb{Z}/36$. The counting rule recovers the 2-part: $\#A[2] = 2^2$ and $\#A[4] = 2^3$, so $N_1 = 2$, $N_2 = 1$, and there is one exponent equal to 1 and one equal to 2, that is, $A[2^\infty] \simeq \mathbb{Z}/2 \oplus \mathbb{Z}/4$. Note that the order alone does not determine A: $\mathbb{Z}/2 \oplus \mathbb{Z}/4$ and $\mathbb{Z}/8$ both have order 8, but $\#A[2]$ is 4 and 2 respectively.

Corollary 1.36 (Cyclicity criteria)**.** *(i) For a finite abelian group A the following are equivalent: A is cyclic; $\#A[\ell] \le \ell$ for every prime ℓ; $\#A[d] \le d$ for every $d \ge 1$.*

(ii) Every finite subgroup of the multiplicative group $K^\times$ of a field K is cyclic. In particular $\mathbb{F}_p^\times$ is cyclic of order $p-1$, more generally $\mathbb{F}_q^\times$ is cyclic of order $q-1$, the group $\mu_n(K)$ of n-th roots of unity in K is cyclic, and the multiplicative group of the field $\mathbb{F}_q[\sqrt{\varepsilon}]$ of Definition 1.54 is cyclic of order q^2-1.

Proof. (i) If $A \simeq \mathbb{Z}/n$, then $\#A[d] = \gcd(d,n) \le d$ by Theorem 1.4(ii). The third condition implies the second. If $\#A[\ell] \le \ell$ for all ℓ, then in the decomposition of Theorem 1.35 each $A[\ell^\infty] \simeq \bigoplus_i \mathbb{Z}/\ell^{e_i}$ has $\#A[\ell] = \ell^{\#\{i\}}$, so it has at most one summand; hence $A \simeq \bigoplus_\ell \mathbb{Z}/\ell^{e_\ell}$, which is cyclic by Proposition 1.13. (ii) Let $A \le K^\times$ be finite. The elements of A with $x^d = 1$ are roots of the polynomial $X^d - 1$, which has at most d roots in the field K; so $\#A[d] \le d$ for all d, and A is cyclic by (i). □

The proof of (ii) is not constructive: it does not exhibit a generator. In small cases one finds one by trial. In $\mathbb{F}_7^\times$, of order 6, the powers of 2 are $2, 4, 1$, so 2 has order 3, while the powers of 3 are $3, 2, 6, 4, 5, 1$, so 3 generates. By Theorem 1.4(iii) there are $\varphi(6) = 2$ generators, 3 and $3^5 = 5$. In $\mathbb{F}_3^\times = \{\pm 1\}$ the generator is -1, and this is the case $\ell - 1 = 2$ of Lemma lem:h0. The hypothesis that K is a field is essential: in the ring $\mathbb{Z}/8$ the polynomial $X^2 - 1$ has the four roots $\pm 1, \pm 3$, and $(\mathbb{Z}/8)^\times \simeq V_4$ is not cyclic.

Proposition 1.37 (Counting torsion)**.** *Let A be a finite abelian group and $n \ge 1$. The sequence $0 \to A[n] \to A \xrightarrow{n} A \to A/nA \to 0$ is exact, and $\#A[n] = \#(A/nA)$. If $A \simeq \bigoplus_i \mathbb{Z}/\ell^{e_i}$ is an ℓ-group, then $\#A[\ell^k] = \#(A/\ell^k A) = \ell^{\sum_i \min(k, e_i)}$.*

Proof. Exactness is the definition of $A[n]$ (the kernel of multiplication by n) and of A/nA (its cokernel). By the first isomorphism theorem $\#nA = \#A/\#A[n]$, so $\#(A/nA) = \#A/\#nA = \#A[n]$. The formula for $\#A[\ell^k]$ was proved in the proof of Theorem 1.35. □

The two groups $A[n]$ and A/nA have the same order but are in general different subquotients of A. For $A = \mathbb{Z}/4$ and $n = 2$, $A[2] = \{0, 2\} = 2A$ and $A/2A \simeq \mathbb{Z}/2$; for $A = \mathbb{Z}/2 \oplus \mathbb{Z}/4$, $A[2] = \{0,1\} \oplus \{0,2\}$ and $A/2A \simeq (\mathbb{Z}/2)^2$, both of order $4 = 2^{\min(1,1)+\min(1,2)}$. The equality of orders is special to finite groups: for $A = \mathbb{Z}$ one has $A[2] = 0$ but $A/2A \simeq \mathbb{Z}/2$.

In the paper 1.38. In the proof of Lemma lem:tamfactor the Frobenius-fixed part of $(\mathbb{Z}/\ell^{v_\ell(n)})^2$ is described by two congruences, $(q-1)y \equiv 0$ and $c'y \equiv 0 \pmod{\ell^{v_\ell(n)}}$, for $y \in \mathbb{Z}/\ell^{v_\ell(n)}$. The solutions form $(\mathbb{Z}/\ell^v)[\ell^w]$ with $v = v_\ell(n)$ and $w = \min(v_\ell(q-1), v_\ell(c'))$, a subgroup of order $\ell^{\min(v,w)} = \ell^{\min(v_\ell(n), v_\ell(q-1), v_\ell(c'))}$ by Theorem 1.4(i) and Proposition 1.37: indeed $\gamma y \equiv 0 \pmod{\ell^v}$ holds iff $\ell^{\min(v, v_\ell(\gamma))} y \equiv 0$, by Theorem 1.4(ii). The lemma itself is proved in Chapter 18; here only the count is at stake.

Example 1.39. The geometric component groups of an elliptic curve (Chapter 10) are $\mathbb{Z}/n$ (type I_n), 0 (types II, II*), $\mathbb{Z}/2$ (types III, III*), $\mathbb{Z}/3$ (types IV, IV*), and $(\mathbb{Z}/2)^2$ or $\mathbb{Z}/4$ (types I_n^*, according to the parity of n). Their ℓ-parts are, by Proposition 1.10, of order $\ell^{v_\ell(n)}$ for $\mathbb{Z}/n$;

for odd ℓ only $\mathbb{Z}/n$ and $\mathbb{Z}/3$ (when $\ell = 3$) can contribute. The groups $(\mathbb{Z}/2)^2$ and $\mathbb{Z}/4$ have the same order but are not isomorphic, since $\#(\mathbb{Z}/2)^2[2] = 4$ and $\#(\mathbb{Z}/4)[2] = 2$. The paper's Section 1.4 and the rule built on Definition def:terms use the component groups only through the numbers $v_\ell(\#\Phi_q^{\mathrm{geom}})$.

1.5 The groups GL_2, SL_2, PGL_2, PSL_2; Borel, unipotent and Cartan subgroups

The Galois representation $\bar\rho_{E,\ell}$ takes values in $\mathrm{GL}_2(\mathbb{F}_\ell)$, and the paper's arguments at $\ell = 3$ are statements about its subgroups. This section introduces the subgroups that occur: the Borel subgroups (the image when E has a rational ℓ-isogeny, the Eisenstein case of Section sec:eis and Conjecture conj:eis), the unipotent elements (the image of inertia in Lemma lem:IV, and "minus a unipotent" in Remark rem:types), the split and nonsplit Cartan subgroups and their normalisers (Proposition prop:ns, Section sec:anomaly, Remark rem:ns), and the action on the projective line, which carries the four lines of $\mathbb{F}_3^2$ of Proposition prop:ns. Throughout, F is a field and $\mathbb{F}_q$ a finite field with q elements (convention (C4)).

Definition 1.40 (Linear groups)**.** $\mathrm{GL}_2(F)$ is the group of invertible 2×2 matrices over F; $\mathrm{SL}_2(F) = \ker(\det\colon \mathrm{GL}_2(F) \to F^\times)$; $\mathrm{PGL}_2(F) = \mathrm{GL}_2(F)/F^\times I$; and $\mathrm{PSL}_2(F) = \mathrm{SL}_2(F)/\{\pm I\}$.

Proposition 1.41. *(i)* $Z(\mathrm{GL}_2(F)) = F^\times I$ *and* $Z(\mathrm{SL}_2(F)) = \{\pm I\}$.

(ii) $\det$ *is surjective,* $d \mapsto \mathrm{diag}(1, d)$ *is a homomorphic section, and* $\mathrm{GL}_2(F) \simeq \mathrm{SL}_2(F) \rtimes F^\times$.

(iii) $\mathrm{SL}_2(F)$ *is generated by the elementary matrices* $\left(\begin{smallmatrix}1 & b\\ 0 & 1\end{smallmatrix}\right)$ *and* $\left(\begin{smallmatrix}1 & 0\\ c & 1\end{smallmatrix}\right)$, $b, c \in F$.

(iv) If $\mathrm{char}\, F \neq 2$, *the only element of order* 2 *of* $\mathrm{SL}_2(F)$ *is* $-I$.

(v) The image of $\mathrm{SL}_2(F)$ *in* $\mathrm{PGL}_2(F)$ *is isomorphic to* $\mathrm{PSL}_2(F)$, *and its index is* $[F^\times : (F^\times)^2]$.

Proof. (i) Let $g = \left(\begin{smallmatrix}a & b\\ c & d\end{smallmatrix}\right)$ commute with $e = \left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$: $ge = \left(\begin{smallmatrix}a & a+b\\ c & c+d\end{smallmatrix}\right)$ and $eg = \left(\begin{smallmatrix}a+c & b+d\\ c & d\end{smallmatrix}\right)$, so $c = 0$ and $a = d$. Commuting with $\left(\begin{smallmatrix}1 & 0\\ 1 & 1\end{smallmatrix}\right)$ gives $b = 0$ in the same way. So g is scalar; conversely scalars are central. Both elementary matrices lie in $\mathrm{SL}_2(F)$, so the same computation gives $Z(\mathrm{SL}_2(F)) = \{aI : a^2 = 1\} = \{\pm I\}$. (ii) $\det \mathrm{diag}(1, d) = d$, and $d \mapsto \mathrm{diag}(1, d)$ is a homomorphism; apply Proposition 1.15(ii). (iii) Let $g = \left(\begin{smallmatrix}a & b\\ c & d\end{smallmatrix}\right) \in \mathrm{SL}_2(F)$. If $c = 0$, multiplying on the left by $\left(\begin{smallmatrix}1 & 0\\ 1 & 1\end{smallmatrix}\right)$ replaces c by $a \neq 0$. So assume $c \neq 0$. Left multiplication by $\left(\begin{smallmatrix}1 & x\\ 0 & 1\end{smallmatrix}\right)$ with $x = (1 - a)/c$ makes the top left entry 1; then left multiplication by $\left(\begin{smallmatrix}1 & 0\\ -c & 1\end{smallmatrix}\right)$ clears the bottom left entry, leaving $\left(\begin{smallmatrix}1 & b'\\ 0 & d'\end{smallmatrix}\right)$ with $d' = 1$ (determinant 1); and left multiplication by $\left(\begin{smallmatrix}1 & -b'\\ 0 & 1\end{smallmatrix}\right)$ gives I. So g is a product of elementary matrices. (iv) If $g^2 = I$, the minimal polynomial of g divides $X^2 - 1 = (X - 1)(X + 1)$, which has distinct roots as $1 \neq -1$; so g is diagonalisable with eigenvalues in $\{\pm 1\}$, and $\det g = 1$ forces them to be equal, so $g = \pm I$. (v) $\mathrm{SL}_2(F) \cap F^\times I = \{\pm I\}$, so the image is $\mathrm{SL}_2(F)F^\times/F^\times \simeq \mathrm{SL}_2(F)/\{\pm I\}$ by Theorem 1.6(ii). The index of this image in $\mathrm{PGL}_2(F) = \mathrm{GL}_2(F)/F^\times I$ is $[\mathrm{GL}_2(F) : \mathrm{SL}_2(F)F^\times I]$, by the correspondence theorem. Now compose $\det\colon \mathrm{GL}_2(F) \to F^\times$, which is surjective by (ii), with the projection $F^\times \to F^\times/(F^\times)^2$. The kernel of the composite consists of the g with $\det g = \lambda^2$ for some $\lambda \in F^\times$; for such g the matrix $\lambda^{-1}g$ has determinant $\lambda^{-2} \det g = 1$, so $g = (\lambda^{-1}g)(\lambda I) \in \mathrm{SL}_2(F)F^\times I$. Conversely $\det(s\lambda I) = \lambda^2$ for $s \in \mathrm{SL}_2(F)$. So the kernel is $\mathrm{SL}_2(F)F^\times I$, and the first isomorphism theorem gives $\mathrm{GL}_2(F)/\mathrm{SL}_2(F)F^\times I \simeq F^\times/(F^\times)^2$. For $F = \mathbb{F}_q$ with q odd the squares form the subgroup

of index 2 of the cyclic group $\mathbb{F}_q^\times$ (Theorem 1.4(ii) with $m = 2$), so $\mathrm{PSL}_2(\mathbb{F}_q)$ has index 2 in $\mathrm{PGL}_2(\mathbb{F}_q)$; for $q = 3$ this is $A_4 \subset S_4$ (Theorem 1.52). For $F = \mathbb{C}$ every element is a square and $\mathrm{PSL}_2(\mathbb{C}) = \mathrm{PGL}_2(\mathbb{C})$. □

The next lemma is the linear algebra behind every conjugacy statement in this chapter.

Lemma 1.42 (Companion form and centralisers)**.** *Let $g \in \mathrm{GL}_2(F)$ be non-scalar. Then there is a vector v such that (v, gv) is a basis, and in this basis g has matrix $\left(\begin{smallmatrix} 0 & -\det g \\ 1 & \operatorname{tr} g \end{smallmatrix}\right)$. Hence two non-scalar matrices are conjugate in $\mathrm{GL}_2(F)$ if and only if they have the same characteristic polynomial. The centraliser of g in $\mathrm{GL}_2(F)$ is $F[g]^\times$, the unit group of the two-dimensional commutative algebra $F[g] = F + Fg \simeq F[X]/(X^2 - \operatorname{tr}(g)X + \det g)$. Over $F = \mathbb{F}_q$: $\#C(g) = q^2 - 1$ if the characteristic polynomial is irreducible, $(q-1)^2$ if it has two distinct roots, and $q(q-1)$ if it has a double root.*

Proof. If every nonzero vector were an eigenvector, then $ge_1 = \alpha e_1$, $ge_2 = \beta e_2$ and $g(e_1 + e_2) = \gamma(e_1 + e_2)$ would give $\alpha = \gamma = \beta$, and g would be scalar. So some v is not an eigenvector, and (v, gv) is a basis. By the Cayley-Hamilton theorem $g^2 v = \operatorname{tr}(g)\, gv - \det(g)\, v$, which gives the matrix. Two non-scalar matrices with the same characteristic polynomial are therefore both conjugate to the same companion matrix. If h commutes with g, write $hv = \alpha v + \beta gv$; then $h(gv) = g(hv) = (\alpha + \beta g)gv$, so h and $\alpha + \beta g$ agree on a basis: $h \in F[g]$. Conversely $F[g]$ commutes with g. As g is not scalar, I and g are linearly independent and $F[g] \simeq F[X]/(\chi_g)$ with χ_g the characteristic polynomial (the minimal polynomial has degree 2). Over $\mathbb{F}_q$ the unit group of $\mathbb{F}_q[X]/(\chi)$ has order $q^2 - 1$ if χ is irreducible (a field with q^2 elements), $(q-1)^2$ if $\chi = (X - \lambda)(X - \mu)$ with $\lambda \neq \mu$ (the ring is $\mathbb{F}_q \times \mathbb{F}_q$ by the Chinese remainder theorem), and $q^2 - q$ if $\chi = (X - \lambda)^2$ (the non-units form the ideal generated by $X - \lambda$, with q elements). □

Two remarks on the lemma. First, the hypothesis "non-scalar" matters: I and $-I$ have characteristic polynomials $(X-1)^2$ and $(X+1)^2$, the same as $u = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ and $-u$, but a scalar matrix is conjugate only to itself. So for the polynomials with a double root there are two classes, the scalar one and the non-scalar one; this is why $\mathrm{GL}_2(\mathbb{F}_3)$ has 8 classes for 6 possible characteristic polynomials (Proposition 1.59). Second, the lemma is used as a counting tool: the class of a non-scalar g in $\mathrm{GL}_2(\mathbb{F}_q)$ has $\#\,\mathrm{GL}_2(\mathbb{F}_q)/\#C(g)$ elements. For $u = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ in $\mathrm{GL}_2(\mathbb{F}_3)$ the centraliser is $\mathbb{F}_3[u]^\times = \{\pm u^m\}$, of order $q(q-1) = 6$, and the class has $48/6 = 8$ elements; for $\sigma = \mathrm{diag}(1, -1)$, with distinct eigenvalues, the centraliser is the diagonal group, of order $(q-1)^2 = 4$, and the class has 12 elements.

Proposition 1.43 (Orders)**.** $\#\,\mathrm{GL}_2(\mathbb{F}_q) = (q^2-1)(q^2-q) = q(q-1)^2(q+1)$, $\#\,\mathrm{SL}_2(\mathbb{F}_q) = \#\,\mathrm{PGL}_2(\mathbb{F}_q) = q(q^2-1)$, *and* $\#\,\mathrm{PSL}_2(\mathbb{F}_q) = q(q^2-1)/\gcd(2, q-1)$. *More generally* $\#\,\mathrm{GL}_n(\mathbb{F}_q) = \prod_{i=0}^{n-1}(q^n - q^i)$. *For small q:*

q	$\#\,\mathrm{GL}_2(\mathbb{F}_q)$	$\#\,\mathrm{SL}_2(\mathbb{F}_q)$	$\#\,\mathrm{PGL}_2(\mathbb{F}_q)$	$\#\,\mathrm{PSL}_2(\mathbb{F}_q)$
3	48	24	24	12
5	480	120	120	60
7	2016	336	336	168

Proof. An invertible matrix is an ordered basis of columns: the first column is any of the $q^2 - 1$ nonzero vectors, the second any of the $q^2 - q$ vectors outside the line of the first; for GL_n the i-th column avoids the q^{i-1} vectors of the span of the previous ones. det is surjective

onto $\mathbb{F}_q^\times$ (Proposition 1.41(ii)), so $\#\,\mathrm{SL}_2 = \#\,\mathrm{GL}_2/(q-1)$; $\#F^\times I = q-1$ gives $\#\,\mathrm{PGL}_2$; and $\#\{\pm I\} = \gcd(2, q-1)$ gives $\#\,\mathrm{PSL}_2$. □

Proposition 1.44 (The projective line)**.** *Let $\mathbb{P}^1(F)$ be the set of lines of F^2 (convention (C1)). Then $\#\mathbb{P}^1(\mathbb{F}_q) = q+1$, and:*

(i) $\mathrm{GL}_2(F)$ *acts on* $\mathbb{P}^1(F)$ *by* $g[v] = [gv]$*; in the coordinate* $x = [x:1]$, $\infty = [1:0]$, *the matrix* $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ *acts by* $x \mapsto (ax+b)/(cx+d)$, *with the usual conventions* $a/0 = \infty$ *for* $a \neq 0$ *and* $\infty \mapsto a/c$.

(ii) The kernel of the action is $F^\times I$, *so* $\mathrm{PGL}_2(F)$ *acts faithfully.*

(iii) $\mathrm{PGL}_2(F)$ *acts sharply* 3*-transitively: for two triples of distinct lines there is exactly one element of* $\mathrm{PGL}_2(F)$ *carrying the first to the second.*

(iv) The stabiliser of $\infty = [e_1]$ *is the upper triangular group* $\mathrm{B}(F)$*; so* $\mathbb{P}^1(F) \simeq \mathrm{GL}_2(F)/\mathrm{B}(F)$ *and* $[\mathrm{GL}_2(\mathbb{F}_q) : \mathrm{B}(\mathbb{F}_q)] = q+1$.

(v) $\mathrm{SL}_2(F)$ *acts* 2*-transitively, in particular transitively, on* $\mathbb{P}^1(F)$.

Proof. There are q^2-1 nonzero vectors, $q-1$ on each line, so $q+1$ lines. (i) $g(\lambda v) = \lambda gv$, so the action is well defined. $g\binom{x}{1} = \binom{ax+b}{cx+d}$, which is the line $(ax+b)/(cx+d)$ if $cx+d \neq 0$ and ∞ otherwise; and $g\binom{1}{0} = \binom{a}{c}$. (ii) An element acting trivially has every nonzero vector as an eigenvector, so it is scalar by the first step of the proof of Lemma 1.42. (iii) Let L_1, L_2, L_3 be distinct lines, $L_i = [v_i]$. Then v_1, v_2 is a basis and $v_3 = \alpha v_1 + \beta v_2$ with $\alpha, \beta \neq 0$ (as $L_3 \neq L_1, L_2$). The matrix g with columns αv_1, βv_2 is invertible and maps $[e_1], [e_2], [e_1+e_2]$, that is $\infty, 0, 1$, to L_1, L_2, L_3. If h fixes ∞, 0 and 1, then $he_1 = \alpha e_1$, $he_2 = \beta e_2$ and $h(e_1+e_2) = \gamma(e_1+e_2)$, so $\alpha = \beta = \gamma$ and h is scalar. So for each triple there is exactly one element of $\mathrm{PGL}_2(F)$ carrying $(\infty, 0, 1)$ to it, and composing gives (iii). (iv) $g[e_1] = [e_1]$ iff the first column $\binom{a}{c}$ is a multiple of e_1, iff $c = 0$. Then apply Theorem 1.28 and (iii) (which gives transitivity): $\#\mathbb{P}^1(\mathbb{F}_q) = [\mathrm{GL}_2(\mathbb{F}_q) : \mathrm{B}(\mathbb{F}_q)]$, and indeed $q(q-1)^2(q+1)/(q(q-1)^2) = q+1$. (v) Given two ordered pairs P, P' of distinct lines, it suffices to find $g, g' \in \mathrm{SL}_2(F)$ moving $(\infty, 0)$ to P and to P', for then $g'g^{-1} \in \mathrm{SL}_2(F)$ moves P to P'. To move $(\infty, 0)$ to $([v_1], [v_2])$: the vectors v_1, v_2 are a basis, so $\det(v_1, v_2) \neq 0$, and the matrix with columns v_1 and λv_2, where $\lambda = \det(v_1, v_2)^{-1}$, has determinant 1, sends $e_1 \mapsto v_1$ and $e_2 \mapsto \lambda v_2$, hence $\infty \mapsto [v_1]$ and $0 \mapsto [v_2]$. (Unlike $\mathrm{PGL}_2(F)$, the group $\mathrm{SL}_2(F)$ need not be 3-transitive: for $F = \mathbb{F}_3$ there are $4 \cdot 3 \cdot 2 = 24$ ordered triples of distinct lines, but $\mathrm{SL}_2(\mathbb{F}_3)$ acts through $\mathrm{PSL}_2(\mathbb{F}_3)$, of order 12.) □

Definition 1.45 (Borel subgroups)**.** A *Borel subgroup* of $\mathrm{GL}_2(F)$ is the stabiliser B_L of a line $L \in \mathbb{P}^1(F)$. We write $\mathrm{B} = \mathrm{B}_{[e_1]} = \{\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)\}$, the upper triangular group; $\mathrm{U} = \{\left(\begin{smallmatrix} 1 & b \\ 0 & 1 \end{smallmatrix}\right) : b \in F\}$, its *unipotent radical*; and $\mathrm{T} = \{\mathrm{diag}(a, d)\}$, the diagonal torus (which is the split Cartan subgroup C_s of Definition 1.54).

Proposition 1.46. *(i)* $\mathrm{U} \simeq (F, +)$ *is normal in* B, *and* $\mathrm{B} = \mathrm{U} \rtimes \mathrm{T}$, *with* T *acting on* U *by*

$$\mathrm{diag}(a,d)\left(\begin{smallmatrix} 1 & b \\ 0 & 1 \end{smallmatrix}\right)\mathrm{diag}(a,d)^{-1} = \left(\begin{smallmatrix} 1 & ab/d \\ 0 & 1 \end{smallmatrix}\right);$$

and $\#\mathrm{B}(\mathbb{F}_q) = q(q-1)^2$.

(ii) The Borel subgroups are all conjugate: $g\mathrm{B}_L g^{-1} = \mathrm{B}_{gL}$. *A Borel subgroup stabilises exactly one line, so* $L \mapsto \mathrm{B}_L$ *is a bijection from* $\mathbb{P}^1(F)$ *to the set of Borel subgroups, and* $N_{\mathrm{GL}_2(F)}(\mathrm{B}_L) = \mathrm{B}_L$.

(iii) A subgroup of $\mathrm{GL}_2(F)$ *stabilises a line of* F^2 *if and only if it is contained in a Borel subgroup.*

(iv) For $q = 3$*:* $\#\mathrm{B}(\mathbb{F}_3) = 12$*, and* $\mathrm{B}(\mathbb{F}_3) = \{\pm I\} \times \langle u, \sigma\rangle \simeq C_2 \times S_3 \simeq D_6$*, with* $u = \left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$ *and* $\sigma = \mathrm{diag}(1, -1)$*. Its image in* $\mathrm{PGL}_2(\mathbb{F}_3)$ *is the stabiliser of* ∞*, isomorphic to* S_3.

Proof. (i) The map $\left(\begin{smallmatrix}a & b\\ 0 & d\end{smallmatrix}\right) \mapsto \mathrm{diag}(a, d)$ is a homomorphism $\mathrm{B} \to \mathrm{T}$ (the diagonal of a product of upper triangular matrices is the product of the diagonals) with kernel U, and it restricts to the identity on T; so Proposition 1.15(ii) applies. The conjugation formula is a direct computation, and $\left(\begin{smallmatrix}1 & b\\ 0 & 1\end{smallmatrix}\right)\left(\begin{smallmatrix}1 & b'\\ 0 & 1\end{smallmatrix}\right) = \left(\begin{smallmatrix}1 & b+b'\\ 0 & 1\end{smallmatrix}\right)$. The order is $q \cdot (q-1)^2$. (ii) $g\mathrm{B}_L g^{-1}$ stabilises gL, and conversely; the action on lines is transitive. The element $\left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$ of B acts by $x \mapsto x + 1$, which fixes ∞ and no point of F; so B stabilises only ∞, and by conjugation B_L stabilises only L. If g normalises B_L, then $\mathrm{B}_L = g\mathrm{B}_L g^{-1} = \mathrm{B}_{gL}$, so $gL = L$ and $g \in \mathrm{B}_L$. (iii) A subgroup H stabilises the line L iff $hL = L$ for every $h \in H$, iff $H \leq \mathrm{B}_L$, by the definition of B_L as the stabiliser of L. (iv) $\#\mathrm{B}(\mathbb{F}_3) = 3 \cdot 4$. Since $\sigma u \sigma^{-1} = \left(\begin{smallmatrix}1 & -1\\ 0 & 1\end{smallmatrix}\right) = u^{-1}$, the subgroup $S = \langle u, \sigma\rangle = \{u^m \sigma^e\}$ has order 6 and is isomorphic to $D_3 \simeq S_3$ by Proposition 1.19(i),(iv). It has index 2 in $\mathrm{B}(\mathbb{F}_3)$, hence is normal; $\{\pm I\}$ is central; and $-I \notin S$ (the elements u^m have trace 2, the elements $u^m\sigma$ determinant -1, while $-I$ has trace $-2 = 1$ and determinant 1). So $\mathrm{B}(\mathbb{F}_3) = \{\pm I\} \times S$ by Proposition 1.12, and $C_2 \times S_3 \simeq D_6$ by Proposition 1.19(iv). The image in $\mathrm{PGL}_2(\mathbb{F}_3)$ is $\mathrm{B}(\mathbb{F}_3)/\{\pm I\} \simeq S$, of order 6, contained in the stabiliser of ∞, which has order $24/4 = 6$ by Theorem 1.28. □

Definition 1.47 (Unipotent elements)**.** An element $u \in \mathrm{GL}_2(F)$ is *unipotent* if $(u-1)^2 = 0$; equivalently, its characteristic polynomial is $(X-1)^2$ (if $(u-1)^2 = 0$, the only eigenvalue of u over $\overline{F}$ is 1; conversely apply the Cayley-Hamilton theorem). For a line L, U_L denotes the group of unipotent elements fixing L pointwise; $\mathrm{U}_{[e_1]} = \mathrm{U}$.

The name records that all eigenvalues equal 1: a unipotent element is $1 + N$ with N nilpotent. Over $\mathbb{F}_p$ these are exactly the elements of p-power order (Proposition 1.48(ii)), and this is why they appear in the paper: in Lemma lem:IV the image of an inertia group in $\mathrm{GL}_2(\mathbb{F}_3)$ has order 3, so it consists of unipotent matrices. For example $u = \left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}1 & 0\\ 1 & 1\end{smallmatrix}\right)$ are unipotent, while $\sigma = \mathrm{diag}(1, -1)$, with eigenvalue -1, is not, and neither is $-u$, whose characteristic polynomial is $(X+1)^2$.

Proposition 1.48. *(i) A unipotent* $u \neq 1$ *is conjugate to* $\left(\begin{smallmatrix}1 & 1\\ 0 & 1\end{smallmatrix}\right)$*. Its fixed vectors form exactly one line,* $\ker(u-1) = \mathrm{im}(u-1)$*, and* u *stabilises no other line of* F^2.

(ii) If $\mathrm{char}\, F = p > 0$*, a unipotent* $u \neq 1$ *has order* p*; conversely every element of* p*-power order of* $\mathrm{GL}_2(F)$ *is unipotent.*

(iii) The unipotent elements of B *are exactly the elements of* U*. For each line* L*,* $\mathrm{U}_L = g\mathrm{U}g^{-1}$ *for any* g *with* $g[e_1] = L$*; it is the unipotent radical of* B_L *and is isomorphic to* $(F, +)$*. The stabiliser of a nonzero vector* v *in* $\mathrm{SL}_2(F)$ *is* $\mathrm{U}_{[v]}$.

(iv) (Minus a unipotent.) If $u \neq 1$ *is unipotent,* $-u$ *has characteristic polynomial* $(X+1)^2$*; if* $\mathrm{char}\, F \neq 2$*, it has no nonzero fixed vector, it stabilises exactly one line (that of* u*), and in characteristic* p *odd it has order* $2p$.

(v) *In* $\mathrm{GL}_2(\mathbb{F}_3)$ *the* 8 *elements of order* 3 *are the nontrivial unipotent elements and form one conjugacy class. They lie in the four subgroups* U_L *of order* 3*, one for each line* L*, which are the Sylow* 3*-subgroups;* U_L *fixes exactly the line* L*. The* 8 *elements of order* 6 *are the elements* $-u$ *with* $u \neq 1$ *unipotent. The* 8 *elements of order* 3 *generate* $\mathrm{SL}_2(\mathbb{F}_3)$*.*

Proof. (i) Let $N = u - 1 \neq 0$. As $N^2 = 0$, $\operatorname{im} N \subseteq \ker N$, and N has rank 1 (rank 2 would make N^2 invertible); so $\ker N = \operatorname{im} N$ is a line L. Choose $v \notin L$ and put $w = Nv$, which spans L. In the basis (w, v), $uw = w$ and $uv = v + w$, so u has matrix $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. The fixed vectors are $\ker N = L$. A line stabilised by u is spanned by an eigenvector, whose eigenvalue is 1, so it is L. (ii) Write $u = 1 + N$ with $N^2 = 0$; then $u^m = 1 + mN$, which is 1 iff $p \mid m$. Conversely if $x^{p^k} = 1$, then $(x-1)^{p^k} = x^{p^k} - 1 = 0$ (the binomial coefficients $\binom{p^k}{i}$, $0 < i < p^k$, vanish in characteristic p), so $x - 1$ is nilpotent; a nilpotent 2×2 matrix has characteristic polynomial X^2 and squares to 0 by Cayley-Hamilton. (iii) An upper triangular matrix with characteristic polynomial $(X-1)^2$ has diagonal entries 1. A unipotent element fixing $L = g[e_1]$ pointwise is $gu'g^{-1}$ with u' unipotent fixing e_1, hence in B, hence in U; conversely U fixes e_1. So $\mathrm{U}_L = g\mathrm{U}g^{-1}$, the kernel of $\mathrm{B}_L \to \mathrm{T}$ transported by g. If $g' \in \mathrm{SL}_2(F)$ fixes $v \neq 0$, complete v to a basis (v, v'); in it $g' = \left(\begin{smallmatrix} 1 & b \\ 0 & d \end{smallmatrix}\right)$ with $d = \det g' = 1$, so g' is unipotent and fixes v; conversely elements of $\mathrm{U}_{[v]}$ fix v and have determinant 1. (iv) $\det(X + u) = (X+1)^2$ follows from $\det(X - u) = (X-1)^2$. If $-uv = v$ then $uv = -v$, but u has only the eigenvalue $1 \neq -1$. The lines stabilised by $-u$ are those stabilised by u. Finally $(-u)^m = (-1)^m u^m = 1$ iff m is even and $p \mid m$, so the order is $2p$ for odd p. (v) By (ii) the elements of order 3 are the nontrivial unipotents; by (i) and Lemma 1.42 they form one class, of size $48/\#C(u) = 48/(3 \cdot 2) = 8$. Each lies in exactly one U_L (its fixed line), and $\#\mathrm{U}_L = 3$; so the four groups U_L contain $4 \cdot 2 = 8$ elements of order 3, and they are the subgroups of order 3, that is, the Sylow 3-subgroups ($48 = 16 \cdot 3$). If x has order 6, then x^3 has order 2 and x^{-2} has order 3, so $x^{-2} = u'$ is a nontrivial unipotent, and x^3 is an involution commuting with u', hence in $C(u') = \mathbb{F}_3[u']^\times = \{\pm u'^m\}$; its only involution is $-I$ (the elements $-u'^m$ with $m \neq 0$ have order 6 by (iv)). So $x = x^3 x^{-2} = -u'$. Conversely the $-u$ have order 6 by (iv); there are 8. Finally let S be the subgroup generated by the 8 elements of order 3. It lies in $\mathrm{SL}_2(\mathbb{F}_3)$ (unipotents have determinant 1), so $\#S$ divides 24, and $\#S \geq 9$; hence $\#S \in \{12, 24\}$. If $\#S = 12$, then S has index 2 in $\mathrm{SL}_2(\mathbb{F}_3)$, hence contains the square of every element of $\mathrm{SL}_2(\mathbb{F}_3)$ (Lemma 1.7: the quotient has order 2); in particular $-I = J^2$ with $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, and then also the 8 elements $-u$. So $\#S \geq 1 + 8 + 1 + 8 = 18$, a contradiction. Hence $S = \mathrm{SL}_2(\mathbb{F}_3)$. □

In the paper 1.49. The proof of Lemma lem:IV uses Proposition 1.48(iii) and (v) in the sentence "The elements of $\mathrm{SL}_2(\mathbb{F}_3)$ fixing a nonzero vector form a group of order 3 of unipotent elements; so $\bar{\rho}_{E,3}(I_q)$ is that group". The image of inertia lies in $\mathrm{SL}_2(\mathbb{F}_3)$ (the cyclotomic character is unramified at $q \neq 3$) and fixes a nonzero vector (since $E[3]^{I_q}$ is a line), so it lies in the stabiliser $\mathrm{U}_{[v]}$ of that vector, of order 3; it is nontrivial, so it equals $\mathrm{U}_{[v]}$, and $E[3]^{I_q}$ is exactly the line $[v]$ by Proposition 1.48(i). Remark rem:types speaks of "minus a unipotent, of order 6" (types II, II*): by Proposition 1.48(iv) such an element fixes no nonzero vector of $\mathbb{F}_3^2$, which is the statement $E[3]^{I_q} = 0$ for these types. The other images listed there, $\{\pm I\}$ and a cyclic group of order 4 (conjugate to $\langle J \rangle$, $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$), also fix no nonzero vector: $-I$ and J have no eigenvalue 1 (Proposition 1.59). For type I_n^* the image of inertia consists of a ramified quadratic character times unipotents; an element on which the character is -1 maps to $-I$ or to minus a nontrivial unipotent, which fixes no nonzero vector by Proposition 1.48(iv), so again $E[3]^{I_q} = 0$. The identification of the images of inertia with the Kodaira types is Chapter 11.

Lemma 1.50 (Commutators in a Borel subgroup)**.** *Let K be a field and $H \leq \mathrm{B}(K)$. Then $[H,H] \leq \mathrm{U}(K)$. If $\operatorname{char} K = p > 0$, then $\mathrm{U}(K)$ is an elementary abelian p-group (every nontrivial element has order p), and:*

(i) a finite subgroup of $\mathrm{B}(K)$ of order prime to p meets $\mathrm{U}(K)$ trivially and is abelian;

(ii) a finite subgroup of $\mathrm{GL}_2(K)$ whose commutator subgroup is not a p-group stabilises no line of K^2.

Proof. The homomorphism $\mathrm{B}(K) \to \mathrm{T}(K) \simeq (K^\times)^2$ of Proposition 1.46(i) has abelian target and kernel $\mathrm{U}(K)$, so it kills all commutators: $[H,H] \leq [\mathrm{B},\mathrm{B}] \leq \mathrm{U}(K)$. In characteristic p, $\mathrm{U}(K) \simeq (K,+)$ and $p \cdot b = 0$. (i) $H \cap \mathrm{U}(K)$ is a p-group (each element has order 1 or p) whose order divides $\#H$, so it is trivial, and $[H,H] \leq H \cap \mathrm{U}(K) = 1$. (ii) If H stabilises a line of K^2, then $gHg^{-1} \leq \mathrm{B}(K)$ for some $g \in \mathrm{GL}_2(K)$ (Proposition 1.46(ii),(iii)), so $g[H,H]g^{-1} \leq \mathrm{U}(K)$, and $[H,H]$ is a finite subgroup of a conjugate of $\mathrm{U}(K)$, hence a p-group. □

In the paper 1.51. In the proof of Proposition prop:ns the determinant-one subgroups $\mathrm{SL}_2(\mathbb{F}_3)$ and Q_8 are shown to act absolutely irreducibly on $\mathbb{F}_3^2$: "a subgroup of $\mathrm{GL}_2(\overline{\mathbb{F}}_3)$ fixing a line lies in a Borel subgroup, so its commutator subgroup is abelian of exponent 3, whereas the commutator subgroups $\{\pm 1\}$ of Q_8 and Q_8 of $\mathrm{SL}_2(\mathbb{F}_3)$ are not." This is Lemma 1.50(ii) with $K = \overline{\mathbb{F}}_3$ and $p = 3$; the commutator subgroups are computed in Proposition 1.21(ii) and Proposition 1.62(iv). Non-abelian and faithful would not be enough here: $\mathrm{B}(\mathbb{F}_3)$ is non-abelian and acts faithfully, yet stabilises a line. That "stabilises no line of $\overline{\mathbb{F}}_3^2$" is the same as "absolutely irreducible" is the definition of Chapter 4.

Theorem 1.52 (PGL_2 and PSL_2 over small fields)**.** *(i) The action on the four lines of $\mathbb{F}_3^2$ induces isomorphisms $\mathrm{PGL}_2(\mathbb{F}_3) \simeq S_4$ and $\mathrm{PSL}_2(\mathbb{F}_3) \simeq A_4$.*

(ii) For $g \in \mathrm{GL}_2(\mathbb{F}_3)$, $\det g \in \mathbb{F}_3^\times = \{\pm 1\}$ equals the sign of the permutation of the four lines induced by g.

(iii) $\mathrm{PGL}_2(\mathbb{F}_5) \simeq S_5$ and $\mathrm{PSL}_2(\mathbb{F}_5) \simeq A_5$.

(iv) $\mathrm{PSL}_2(\mathbb{F}_q)$ is simple for $q \geq 4$. In particular $\mathrm{PSL}_2(\mathbb{F}_7)$ is simple of order 168; it is isomorphic to $\mathrm{GL}_3(\mathbb{F}_2)$.

Proof. (i) By Proposition 1.44(ii) the action gives an injective homomorphism $\mathrm{PGL}_2(\mathbb{F}_3) \to S_4$, and both groups have order 24. The group $\mathrm{SL}_2(\mathbb{F}_3)$ is generated by its elements of order 3 (Proposition 1.48(v)), whose images have order 3 in S_4, hence are 3-cycles, hence even; so the image of $\mathrm{SL}_2(\mathbb{F}_3)$, which is $\mathrm{PSL}_2(\mathbb{F}_3)$ by Proposition 1.41(v), lies in A_4, and it has order 12. (ii) Both det and $g \mapsto \operatorname{sgn}(\text{permutation})$ are homomorphisms $\mathrm{GL}_2(\mathbb{F}_3) \to \{\pm 1\}$. The kernel of det is $\mathrm{SL}_2(\mathbb{F}_3)$, which lies in the kernel of the sign by (i). The sign is not trivial: $\sigma = \operatorname{diag}(1,-1)$ acts by $x \mapsto -x$, fixing 0 and ∞ and swapping 1 and -1, a transposition. So both kernels have index 2 and contain $\mathrm{SL}_2(\mathbb{F}_3)$, hence are equal to it, and two homomorphisms onto $\{\pm 1\}$ with the same kernel are equal. □

We do not prove (iv); see [109, Chapter XIII, Section 8] for the simplicity of $\mathrm{PSL}_2(F)$ for every field with more than three elements (the proof uses the 2-transitivity of Proposition 1.44(v), the generation by the conjugates of U of Proposition 1.41(iii), and Iwasawa's criterion), and [58, Section 6.2] for the uniqueness of the simple group of order 168, which identifies $\mathrm{PSL}_2(\mathbb{F}_7)$ with $\mathrm{GL}_3(\mathbb{F}_2)$.

Sketch of proof of (iii). Granting the simplicity of $\mathrm{PSL}_2(\mathbb{F}_5)$ (order 60): the subgroup of $\mathrm{GL}_2(\mathbb{F}_5)$ generated by $N_s(\mathbb{F}_5)$ (Definition 1.54) and $\left(\begin{smallmatrix}1 & 1\\ 1 & -1\end{smallmatrix}\right)$ has order 96 and contains the scalars (this is a finite check, done by machine; note $\left(\begin{smallmatrix}1 & 1\\ 1 & -1\end{smallmatrix}\right)^2 = 2I$), so its image K in $\mathrm{PGL}_2(\mathbb{F}_5)$ has order 24 and index 5. The action of $\mathrm{PGL}_2(\mathbb{F}_5)$ on the five cosets of K gives a homomorphism to S_5 whose kernel M is normal and contained in K. Then $M \cap \mathrm{PSL}_2(\mathbb{F}_5)$ is normal in the simple group $\mathrm{PSL}_2(\mathbb{F}_5)$ and has order at most $24 < 60$, so it is trivial, and $\#M \le 2$; a normal subgroup of order 2 would be central, but the centre of $\mathrm{PGL}_2(\mathbb{F}_5)$ is trivial (a central element z maps each point x to a point fixed by the stabiliser of x, which is transitive on the other five points by Proposition 1.44(iii); so $zx = x$ for all x, and $z = 1$ by Proposition 1.44(ii)). So $\mathrm{PGL}_2(\mathbb{F}_5) \to S_5$ is injective, hence bijective, and it maps the index-2 subgroup $\mathrm{PSL}_2(\mathbb{F}_5)$ onto the unique index-2 subgroup A_5 of S_5. See [85, Chapter II, Section 8] for a full treatment of the small $\mathrm{PSL}_2(\mathbb{F}_q)$ and their exceptional isomorphisms. □

In the paper 1.53. Theorem 1.52(ii) is behind the parity of the permutation of the roots of the 3-division polynomial in Proposition prop:ns: the four roots correspond to the four lines of $E[3]$ (Chapter 9), and $\sigma \in G_{\mathbb{Q}}$ permutes them with sign $\det \bar{\rho}_{E,3}(\sigma) = \chi_{-3}(\sigma)$. So the discriminant of the 3-division polynomial is -3 times a square; this is taken up in Chapter 5 and Chapter 11.

Definition 1.54 (Cartan subgroups and their normalisers)**.** Let q be odd and fix a non-square $\varepsilon \in \mathbb{F}_q^\times$ (for $q = 3$ we take $\varepsilon = -1$; for $q = 5$, $\varepsilon = 2$; for $q = 7$, $\varepsilon = 3$). Put $w = \left(\begin{smallmatrix}0 & 1\\ 1 & 0\end{smallmatrix}\right)$ and $\sigma = \mathrm{diag}(1, -1)$.

(i) The *split Cartan subgroup* is $C_s(\mathbb{F}_q) = \{\mathrm{diag}(a, d) : a, d \in \mathbb{F}_q^\times\} \simeq (\mathbb{F}_q^\times)^2$, and $N_s(\mathbb{F}_q) = C_s(\mathbb{F}_q) \cup wC_s(\mathbb{F}_q)$.

(ii) Let $\mathbb{F}_q[\sqrt{\varepsilon}] = \{a + b\sqrt{\varepsilon} : a, b \in \mathbb{F}_q\}$, with $(\sqrt{\varepsilon})^2 = \varepsilon$, that is, $\mathbb{F}_q[X]/(X^2 - \varepsilon)$. The *nonsplit Cartan subgroup* is

$$C_{ns}(\mathbb{F}_q) = \left\{ \begin{pmatrix} a & \varepsilon b \\ b & a \end{pmatrix} : (a, b) \neq (0, 0) \right\},$$

the matrices of multiplication by $a + b\sqrt{\varepsilon}$ on $\mathbb{F}_q[\sqrt{\varepsilon}]$ in the basis $(1, \sqrt{\varepsilon})$, and $N_{ns}(\mathbb{F}_q) = C_{ns}(\mathbb{F}_q) \cup C_{ns}(\mathbb{F}_q)\sigma$.

A *Cartan subgroup* of $\mathrm{GL}_2(\mathbb{F}_q)$ is a conjugate of $C_s(\mathbb{F}_q)$ (split) or of $C_{ns}(\mathbb{F}_q)$ (nonsplit). We often drop $(\mathbb{F}_q)$ from the notation.

The definition is made because these are the centralisers of the "generic" semisimple elements. By Lemma 1.42, a matrix whose characteristic polynomial has two distinct roots in $\mathbb{F}_q$ is conjugate to a diagonal matrix with distinct entries, whose centraliser is C_s; a matrix whose characteristic polynomial is irreducible over $\mathbb{F}_q$ has centraliser $\mathbb{F}_q[g]^\times \simeq \mathbb{F}_{q^2}^\times$, a conjugate of C_{ns} (Proposition 1.55(iv)). Consequently an abelian subgroup $H \le \mathrm{GL}_2(\mathbb{F}_q)$ of order prime to the characteristic p lies in a Cartan subgroup. If H consists of scalars, it lies in C_s. Otherwise choose a non-scalar $h \in H$. Its characteristic polynomial has no double root λ: otherwise $\lambda^{-1}h$ would be a nontrivial unipotent element, of order p (Proposition 1.48(ii)), and $h^m = \lambda^m(\lambda^{-1}h)^m = 1$ would force $(\lambda^{-1}h)^m$ to be a scalar unipotent matrix, that is 1, so $p \mid m$ and p would divide the order of h. So $C(h) = \mathbb{F}_q[h]^\times$ is a Cartan subgroup, and it contains H because H is abelian. Dickson's classification (Theorem 1.57) is phrased in terms of these groups and their normalisers. The choice of ε only changes C_{ns} by conjugation (Proposition 1.55(iv)). For $q = 3$ and $\varepsilon = -1$: $C_{ns}(\mathbb{F}_3)$ is the set of the 8 matrices $\left(\begin{smallmatrix}a & -b\\ b & a\end{smallmatrix}\right)$ with $(a, b) \neq (0, 0)$, the matrices of multiplication by $a + bi$ on $\mathbb{F}_9 = \mathbb{F}_3[i]$, and it contains $J = \left(\begin{smallmatrix}0 & 1\\ -1 & 0\end{smallmatrix}\right)$ (take $a = 0$, $b = -1$).

Proposition 1.55. *Let q be odd.*

(i) $N_s = N_{\mathrm{GL}_2(\mathbb{F}_q)}(C_s)$*, and it is the stabiliser of the set of two lines* $\{[e_1],[e_2]\}$*;* C_s *is the subgroup fixing each of the two lines, and* $N_s = C_s \rtimes \langle w\rangle$*.*

(ii) $\mathbb{F}_q[\sqrt{\varepsilon}]$ *is a field with* q^2 *elements, and* $c \mapsto m_c$ *(multiplication by* c*) is an isomorphism* $\mathbb{F}_q[\sqrt{\varepsilon}]^\times \to C_{ns}$*, with* $\det m_c = a^2 - \varepsilon b^2$ *(the norm* $N(c) = c\bar{c}$*, where* $\bar{c} = a - b\sqrt{\varepsilon}$*) and* $\operatorname{tr} m_c = 2a$*. So* C_{ns} *is cyclic of order* $q^2 - 1$*.*

(iii) The conjugation $c \mapsto \bar{c}$ *is the field automorphism* $c \mapsto c^q$*, its matrix is* σ*, and* $\sigma m_c \sigma^{-1} = m_{\bar{c}} = m_c^q$*. Moreover* $N_{ns} = N_{\mathrm{GL}_2(\mathbb{F}_q)}(C_{ns}) = C_{ns} \rtimes \langle\sigma\rangle$*.*

(iv) All split Cartan subgroups are conjugate, and all nonsplit ones are conjugate. Intrinsically, a Cartan subgroup is the unit group $A^\times$ *of a two-dimensional commutative subalgebra* $A \subset M_2(\mathbb{F}_q)$ *that is isomorphic to* $\mathbb{F}_q \times \mathbb{F}_q$ *(split) or is a field (nonsplit). Each Cartan subgroup has index* 2 *in its normaliser.*

Proof. (i) $w \operatorname{diag}(a,d)\, w^{-1} = \operatorname{diag}(d,a)$, so w normalises C_s, and N_s is a group containing C_s with index 2 ($w \notin C_s$). An element fixing both $[e_1]$ and $[e_2]$ is diagonal; an element swapping them is w times a diagonal matrix. So N_s is the stabiliser of $\{[e_1],[e_2]\}$. Conversely let g normalise C_s. As $q \geq 3$, there is $d \neq 1$ in $\mathbb{F}_q^\times$, and $\operatorname{diag}(1,d)$ has distinct eigenvalues, so the lines stabilised by every element of C_s are exactly $[e_1]$ and $[e_2]$. Since $gC_sg^{-1} = C_s$, g maps this set of two lines to itself, so $g \in N_s$. The semidirect product structure follows from Proposition 1.15(i).

(ii) $\mathbb{F}_q[\sqrt{\varepsilon}]$ is a commutative ring with q^2 elements. For $(a,b) \neq (0,0)$, $a^2 - \varepsilon b^2 \neq 0$: if $b \neq 0$ this would make $\varepsilon = (a/b)^2$ a square, and if $b = 0$ then $a \neq 0$. So $(a + b\sqrt{\varepsilon})^{-1} = (a - b\sqrt{\varepsilon})/(a^2 - \varepsilon b^2)$, and it is a field. Multiplication by $c = a + b\sqrt{\varepsilon}$ sends $1 \mapsto a + b\sqrt{\varepsilon}$ and $\sqrt{\varepsilon} \mapsto \varepsilon b + a\sqrt{\varepsilon}$, which gives the matrix $\left(\begin{smallmatrix} a & \varepsilon b \\ b & a \end{smallmatrix}\right)$, with the stated determinant and trace; $c \mapsto m_c$ is an injective homomorphism. Cyclicity is Corollary 1.36(ii).

(iii) $\bar{c}$ is a ring automorphism (it is the substitution $\sqrt{\varepsilon} \mapsto -\sqrt{\varepsilon}$, and $-\sqrt{\varepsilon}$ is also a root of $X^2 - \varepsilon$), with matrix σ in the basis $(1, \sqrt{\varepsilon})$. In characteristic p, $(x+y)^p = x^p + y^p$, so $c \mapsto c^q$ is a ring endomorphism; it fixes $\mathbb{F}_q$ (as $a^{q-1} = 1$ for $a \in \mathbb{F}_q^\times$, by Lagrange) and sends $\sqrt{\varepsilon}$ to $\varepsilon^{(q-1)/2}\sqrt{\varepsilon}$. Now $\varepsilon^{(q-1)/2} = -1$ (Euler's criterion): in the cyclic group $\mathbb{F}_q^\times = \langle t\rangle$ (Corollary 1.36) of even order $q-1$, the squares are the even powers of t, since $q-1$ is even; so $\varepsilon = t^m$ with m odd, and $\varepsilon^{(q-1)/2} = t^{m(q-1)/2} \neq 1$, as $q - 1 \nmid m(q-1)/2$. Its square is 1, and the only roots of $X^2 - 1$ in a field are ± 1; so it is -1. Hence $c^q = \bar{c}$. Then $\sigma m_c \sigma^{-1}$ is the matrix of $x \mapsto \overline{c}\,\overline{x} = \bar{c}x$, that is $m_{\bar{c}}$. So σ normalises C_{ns}; $\sigma \notin C_{ns}$ (it is not of the form $\left(\begin{smallmatrix} a & \varepsilon b \\ b & a \end{smallmatrix}\right)$, as $1 \neq -1$), and N_{ns} is a group in which C_{ns} has index 2. Conversely let g normalise C_{ns}. The $\mathbb{F}_q$-span of C_{ns} is the image A of the field $\mathbb{F}_q[\sqrt{\varepsilon}]$, and $x \mapsto gxg^{-1}$ is a ring automorphism of A fixing the scalars; it sends $m_{\sqrt{\varepsilon}}$ to a square root of εI in A, that is to $\pm m_{\sqrt{\varepsilon}}$ (a polynomial of degree 2 has at most two roots in a field). If it fixes $m_{\sqrt{\varepsilon}}$, then g commutes with the non-scalar matrix $m_{\sqrt{\varepsilon}}$, so $g \in \mathbb{F}_q[m_{\sqrt{\varepsilon}}]^\times = C_{ns}$ by Lemma 1.42. Otherwise $g\sigma^{-1}$ commutes with $m_{\sqrt{\varepsilon}}$, so $g \in C_{ns}\sigma$.

(iv) Let $A \subset M_2(\mathbb{F}_q)$ be a two-dimensional commutative subalgebra (containing I). If $A \simeq \mathbb{F}_q \times \mathbb{F}_q$, its idempotent e corresponding to $(1,0)$ satisfies $e^2 = e \neq 0, 1$, so e is the projection onto a line L_1 along a line L_2 ($F^2 = \operatorname{im} e \oplus \ker e$, both of dimension 1), and $A = \{\alpha e + \beta(1-e)\}$ is the set of matrices acting by scalars on L_1 and on L_2; in a basis $v_1 \in L_1$, $v_2 \in L_2$, $A^\times$ becomes C_s. If A is a field (with q^2 elements), then $\mathbb{F}_q^2$ is an A-module, and for $v \neq 0$ the map $A \to \mathbb{F}_q^2$, $x \mapsto xv$, is injective (A is a field) and hence bijective by counting. The element $\varepsilon \in \mathbb{F}_q^\times \subset A^\times$ is a square in A: $A^\times$ is cyclic of order $q^2 - 1$, its subgroup $\mathbb{F}_q^\times$ of order $q-1$ consists of the $(q+1)$-th

powers (Theorem 1.4(i)), and $q+1$ is even. Choose $\delta \in A$ with $\delta^2 = \varepsilon I$; then in the basis $(v, \delta v)$ the elements $a + b\delta$ of A have matrices $\left(\begin{smallmatrix} a & \varepsilon b \\ b & a \end{smallmatrix}\right)$, so $A^\times$ becomes C_{ns}. Conversely C_s and C_{ns} are of this form, with A the diagonal matrices and the image of $\mathbb{F}_q[\sqrt{\varepsilon}]$. The index statement is (i) and (iii) transported by conjugation. □

Proposition 1.56 (Facts about Cartan subgroups)**.** *Let q be odd.*

(i) $\#C_s = (q-1)^2$, $\#N_s = 2(q-1)^2$, $\#C_{ns} = q^2-1$, $\#N_{ns} = 2(q^2-1)$. *For $q = 3, 5, 7$ these are $4, 16, 36$; $8, 32, 72$; $8, 24, 48$; $16, 48, 96$, and $\#\mathrm{B} = 12, 80, 252$.*

(ii) Every element of $N_s \setminus C_s$ and of $N_{ns} \setminus C_{ns}$ has trace 0. In N_s, $\left(\begin{smallmatrix} 0 & b \\ c & 0 \end{smallmatrix}\right)^2 = bc\, I$ and $\det\left(\begin{smallmatrix} 0 & b \\ c & 0 \end{smallmatrix}\right) = -bc$. In N_{ns}, $(m_c\sigma)^2 = N(c)\, I$ and $\det(m_c\sigma) = -N(c)$.

(iii) $\det(C_{ns}) = \mathbb{F}_q^\times$*: the norm $\mathbb{F}_q[\sqrt{\varepsilon}]^\times \to \mathbb{F}_q^\times$ is surjective, with kernel of order $q+1$.*

(iv) $C_s \cap \mathrm{SL}_2 \simeq C_{q-1}$, $\#(N_s \cap \mathrm{SL}_2) = 2(q-1)$, $C_{ns} \cap \mathrm{SL}_2 \simeq C_{q+1}$, $\#(N_{ns} \cap \mathrm{SL}_2) = 2(q+1)$.

(v) The orbits on $\mathbb{P}^1(\mathbb{F}_q)$ (coordinate x of (C1)) are: for C_s, $\{\infty\}$, $\{0\}$, $\mathbb{F}_q^\times$; for N_s, $\{0, \infty\}$, $\mathbb{F}_q^\times$; for B*, $\{\infty\}$, $\mathbb{F}_q$. The group C_{ns} acts simply transitively on $\mathbb{F}_q^2 \setminus \{0\}$, and $C_{ns}/\mathbb{F}_q^\times I \simeq C_{q+1}$ acts simply transitively on $\mathbb{P}^1(\mathbb{F}_q)$; hence C_{ns} and N_{ns} are transitive on $\mathbb{P}^1(\mathbb{F}_q)$ and stabilise no line of $\mathbb{F}_q^2$.*

Proof. (i) The cosets wC_s and $C_{ns}\sigma$ are disjoint from C_s and C_{ns}, so the normalisers have twice the order; the numbers follow (and were checked by enumeration). (ii) wC_s consists of the matrices $\left(\begin{smallmatrix} 0 & b \\ c & 0 \end{smallmatrix}\right)$, and $m_c\sigma = \left(\begin{smallmatrix} a & -\varepsilon b \\ b & -a \end{smallmatrix}\right)$ has trace 0. The squares: $\left(\begin{smallmatrix} 0 & b \\ c & 0 \end{smallmatrix}\right)^2 = \left(\begin{smallmatrix} bc & 0 \\ 0 & bc \end{smallmatrix}\right)$, and $(m_c\sigma)^2 = m_c\,\sigma m_c \sigma^{-1}\,\sigma^2 = m_c m_{\bar{c}} = m_{c\bar{c}} = N(c)I$. The determinants are immediate. (iii) $N(c) = c\bar{c} = c^{q+1}$ by Proposition 1.55(iii). On the cyclic group $\mathbb{F}_q[\sqrt{\varepsilon}]^\times$ of order q^2-1 the $(q+1)$-th power map has kernel of order $\gcd(q+1, q^2-1) = q+1$ and image of order $q-1$ (Theorem 1.4(ii)), contained in $\mathbb{F}_q^\times$ (as $N(c) = a^2 - \varepsilon b^2 \in \mathbb{F}_q$), which has order $q-1$. (iv) $C_s \cap \mathrm{SL}_2 = \{\mathrm{diag}(a, a^{-1})\} \simeq \mathbb{F}_q^\times$; in wC_s the determinant-one elements $\left(\begin{smallmatrix} 0 & b \\ c & 0 \end{smallmatrix}\right)$ have $bc = -1$, and there are $q-1$ of them. $C_{ns} \cap \mathrm{SL}_2$ is the kernel of the norm, cyclic (as a subgroup of a cyclic group) of order $q+1$; in $C_{ns}\sigma$ the determinant-one elements are the $m_c\sigma$ with $N(c) = -1$, a fibre of the surjective norm, with $q+1$ elements. (v) $\mathrm{diag}(a, d)$ acts by $x \mapsto ax/d$, fixing 0 and ∞ and acting transitively on $\mathbb{F}_q^\times$ (take $a = x'/x$, $d = 1$); w acts by $x \mapsto 1/x$, swapping 0 and ∞; $\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)$ acts by $x \mapsto (ax+b)/d$, fixing ∞ and transitive on $\mathbb{F}_q$. Identifying $\mathbb{F}_q^2$ with $\mathbb{F}_q[\sqrt{\varepsilon}]$ through the basis $(1, \sqrt{\varepsilon})$, C_{ns} acts by multiplication by the nonzero elements of a field, which is simply transitive on the nonzero elements. If m_c stabilises the line $\mathbb{F}_q v$, then $cv = \lambda v$ with $\lambda \in \mathbb{F}_q$, so $(c-\lambda)v = 0$ and $c = \lambda$: the stabiliser of every line is $\mathbb{F}_q^\times I$. By Theorem 1.28 the orbit of a line has $(q^2-1)/(q-1) = q+1$ elements, which is all of $\mathbb{P}^1(\mathbb{F}_q)$, and $C_{ns}/\mathbb{F}_q^\times I$ (cyclic of order $q+1$) acts simply transitively. Since $q+1 \geq 2$, no line is fixed. □

Theorem 1.57 (Dickson)**.** *Let ℓ be an odd prime, $G \leq \mathrm{GL}_2(\mathbb{F}_\ell)$ a subgroup and $\bar{G}$ its image in $\mathrm{PGL}_2(\mathbb{F}_\ell)$.*

(a) If $\ell \mid \#G$, then either $G \supseteq \mathrm{SL}_2(\mathbb{F}_\ell)$ or G is contained in a Borel subgroup.

(b) If $\ell \nmid \#G$, then exactly one of the following holds: $\bar{G}$ is cyclic and G is contained in a Cartan subgroup (split or nonsplit); $\bar{G}$ is dihedral of order $2n$ with $n \geq 2$, and G is contained in the normaliser of a Cartan subgroup but not in the Cartan subgroup; $\bar{G}$ is isomorphic to A_4, S_4 or A_5 (the exceptional *case).*

Consequently a subgroup of $\mathrm{GL}_2(\mathbb{F}_\ell)$ *not containing* $\mathrm{SL}_2(\mathbb{F}_\ell)$ *is contained in a Borel subgroup, in the normaliser of a split or a nonsplit Cartan subgroup, or in the preimage of an exceptional subgroup of* $\mathrm{PGL}_2(\mathbb{F}_\ell)$.

We do not prove this; see [171, Section 2, Propositions 15 and 16] and, for the original classification of the subgroups of $\mathrm{PSL}_2(\mathbb{F}_q)$, [54]. For $\ell = 3$ the part needed in the paper is proved below (Proposition 1.61 and Theorem 1.65). Its statement for PGL_2 and its use for representations is in Chapter 4, and the list of the images that occur for elliptic curves over $\mathbb{Q}$ is in Chapter 11.

Warning 1.58. Theorem 1.57 is a list of containments, not a list of maximal subgroups. For $\ell = 3$ the standard models satisfy $N_s(\mathbb{F}_3) \subset N_{ns}(\mathbb{F}_3)$, with index 2 (Proposition 1.63(vii)). For $\ell = 5$, $N_s(\mathbb{F}_5)$ (order 32, a Sylow 2-subgroup of $\mathrm{GL}_2(\mathbb{F}_5)$) lies in a subgroup of order 96 whose image in $\mathrm{PGL}_2(\mathbb{F}_5)$ is isomorphic to S_4 (checked by enumeration; see the proof sketch of Theorem 1.52(iii)). So $N_s(\mathbb{F}_\ell)$ must not be called maximal for $\ell = 3$ or $\ell = 5$. The two cases of Proposition prop:ns are distinguished by orbits and by determinant-one subgroups, not by maximality.

1.6 The group $\mathrm{GL}_2(\mathbb{F}_3)$ in full, and $\mathrm{GL}_2(\mathbb{F}_5)$, $\mathrm{GL}_2(\mathbb{F}_7)$

This section is the group-theoretic core of Proposition prop:ns and of the boundary case studied in Section sec:anomaly. We determine the conjugacy classes and the subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$, identify $N_s(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ and their determinant-one subgroups, and prove that the three properties used in the paper (surjective determinant, no stable line, an element of determinant -1 and trace 0) leave exactly the three images $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$, $N_s(\mathbb{F}_3)$ (Theorem 1.65), distinguished by their orbits on the four lines (Corollary 1.66). The Galois-theoretic side (that the image of complex conjugation has determinant -1 and trace 0, that the roots of the 3-division polynomial correspond to lines, and the list of images that occur) is in Chapter 5, Chapter 9 and Chapter 11.

Notation for this section. $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ (so $J^2 = -I$ and $J^{-1} = -J$), $\sigma = \mathrm{diag}(1, -1)$, $w = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right) = \sigma J$, $u = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. This J is the paper's (Proposition prop:ns and Section sec:anomaly), and the book uses it throughout. Note $J\sigma = -w$ and $J = m_{-i}$ in the notation of Proposition 1.55 (with $\varepsilon = -1$), so that $m_i = -J = J^{-1}$. The four lines of $\mathbb{F}_3^2$ are $\infty = [1 : 0]$, $0 = [0 : 1]$, $1 = [1 : 1]$ and $-1 = [-1 : 1]$ (convention (C1)).

Proposition 1.59 (Conjugacy classes of $\mathrm{GL}_2(\mathbb{F}_3)$)**.** $\mathrm{GL}_2(\mathbb{F}_3)$ *has order* 48*, centre* $\{\pm I\}$*, commutator subgroup* $\mathrm{SL}_2(\mathbb{F}_3)$*, and exactly* 8 *conjugacy classes:*

representative	*size*	*order*	det	tr	*char. polynomial*	*lines fixed*	*image in* S_4
I	1	1	1	-1	$(X-1)^2$	4	*identity*
$-I$	1	2	1	1	$(X+1)^2$	4	*identity*
σ	12	2	-1	0	X^2-1	2	*transposition*
u	8	3	1	-1	$(X-1)^2$	1	3-*cycle*
J	6	4	1	0	X^2+1	0	*double transposition*
$-u$	8	6	1	1	$(X+1)^2$	1	3-*cycle*
$\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$	6	8	-1	-1	X^2+X-1	0	4-*cycle*
$\left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$	6	8	-1	1	X^2-X-1	0	4-*cycle*

The class of a non-scalar element is determined by its characteristic polynomial. The numbers of elements of orders $1, 2, 3, 4, 6, 8$ *are* $1, 13, 8, 6, 8, 12$.

Proof. The order is Proposition 1.43 and the centre is Proposition 1.41(i). By Lemma 1.42 the non-scalar classes correspond to the characteristic polynomials X^2-tX+d with $t \in \mathbb{F}_3$, $d \in \{\pm 1\}$, all six of which occur (companion matrices), and there are two scalar classes; that makes 8. The polynomial X^2-1 has distinct roots ± 1; $(X \mp 1)^2$ are the two with a double root; and X^2+1, X^2+X-1, X^2-X-1 have no root in $\mathbb{F}_3$ (evaluate at $0, 1, -1$), so they are irreducible. By Lemma 1.42 the centralisers have orders 4, 6, 8 in these three cases, giving class sizes 12, 8, 6; and $1+1+12+8+6+8+6+6 = 48$. The representatives listed have the stated characteristic polynomials. Orders: $\sigma^2 = I$; u and $-u$ have orders 3 and 6 by Proposition 1.48(ii),(iv); $J^2 = -I$. An element g with irreducible characteristic polynomial generates a subgroup of $\mathbb{F}_3[g]^\times$, a cyclic group of order 8 (it is the unit group of a field with 9 elements, Corollary 1.36); if $g^4 = 1$, its eigenvalues in that field satisfy $\lambda^4 = 1$, so $\lambda \in \{\pm 1, \pm\sqrt{-1}\}$, and as $\lambda \notin \mathbb{F}_3$ the characteristic polynomial is X^2+1. For the last two classes the characteristic polynomial is $X^2 \pm X - 1 \neq X^2+1$, so the order divides 8 but not 4: these elements have order 8. (Directly: $a = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ has $a^2 = \left(\begin{smallmatrix} 0 & -2 \\ 2 & 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right) = J$, of order 4.) The lines fixed are the eigenlines over $\mathbb{F}_3$: two for σ, one for $\pm u$ (Proposition 1.48), none for an irreducible characteristic polynomial, all four for $\pm I$. The image in S_4 (Theorem 1.52(i)) has order equal to the order of the element modulo $\{\pm I\}$, and its number of fixed points is the number of fixed lines: order 2 with two fixed points is a transposition, order 3 is a 3-cycle, order 2 with no fixed point (J, since $J^2 = -I$) is a double transposition, and order 4 (for elements g of order 8, $g^4 = -I$, g^2 not scalar) is a 4-cycle. Commutator subgroup: it lies in $\mathrm{SL}_2(\mathbb{F}_3)$, as det kills commutators; and $\sigma u \sigma^{-1} u^{-1} = u^{-2} = u$ is a commutator, so the normal subgroup $[\mathrm{GL}_2(\mathbb{F}_3), \mathrm{GL}_2(\mathbb{F}_3)]$ contains the whole class of u, which generates $\mathrm{SL}_2(\mathbb{F}_3)$ (Proposition 1.48(v)). The order statistics are read off the table: order 2 gives $1+12 = 13$ elements ($-I$ and the class of σ), order 8 gives $6+6 = 12$, and the others are single classes. (The check $\sigma u \sigma^{-1} = u^{-1}$: $\sigma u \sigma^{-1}$ replaces the off-diagonal entry 1 of u by -1, and $u^{-1} = \left(\begin{smallmatrix} 1 & -1 \\ 0 & 1 \end{smallmatrix}\right)$; so $\sigma u \sigma^{-1} u^{-1} = u^{-2}$, which equals u as $u^3 = I$.) □

Convention 1.60 (Standard models)**.** The following models are fixed for the whole book (with $\varepsilon = -1$ in Definition 1.54, so that $\mathbb{F}_3[\sqrt{-1}] = \mathbb{F}_3[i]$ is the field with 9 elements and $J = m_{-i} = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$):

$$C_s(\mathbb{F}_3) = \{\mathrm{diag}(\pm 1, \pm 1)\} \simeq V_4, \qquad N_s(\mathbb{F}_3) = C_s(\mathbb{F}_3) \cup wC_s(\mathbb{F}_3) = \langle J, \sigma \rangle,$$

$$C_{ns}(\mathbb{F}_3) = \left\{ \begin{pmatrix} a & -b \\ b & a \end{pmatrix} : (a,b) \neq (0,0) \right\}, \qquad N_{ns}(\mathbb{F}_3) = C_{ns}(\mathbb{F}_3) \cup C_{ns}(\mathbb{F}_3)\sigma,$$

$$\mathrm{B}(\mathbb{F}_3) = \{\text{upper triangular}\}, \qquad \mathrm{U} = \langle u \rangle,$$

$$Q_8 = \left\{ \pm I, \ \pm J, \ \pm \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}, \ \pm \begin{pmatrix} 1 & -1 \\ -1 & -1 \end{pmatrix} \right\}, \qquad C_4 = \langle J \rangle = \{\pm I, \pm J\}.$$

"The image is $N_s(\mathbb{F}_3)$" always means "the image is conjugate to this model" (convention (C5)). With these models $N_s(\mathbb{F}_3) \subset N_{ns}(\mathbb{F}_3)$ and $C_4 = N_s(\mathbb{F}_3) \cap \mathrm{SL}_2(\mathbb{F}_3) = C_{ns}(\mathbb{F}_3) \cap \mathrm{SL}_2(\mathbb{F}_3)$ (Proposition 1.63, Proposition 1.64). The paper's macro 3Ns prints Sutherland's label of the image, not the group.

Proposition 1.61 (Subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$)**.** $\mathrm{GL}_2(\mathbb{F}_3)$ *has* 55 *subgroups, in* 16 *conjugacy classes:*

order	*type*	*conjugates*	*stable lines*	*orbits on* $\mathbb{P}^1(\mathbb{F}_3)$	det *onto*	$\det -1$, $\mathrm{tr}\,0$	*name*
1	1	1	4	1, 1, 1, 1	*no*	*no*	
2	C_2	1	4	1, 1, 1, 1	*no*	*no*	$\{\pm I\}$
2	C_2	12	2	1, 1, 2	*yes*	*yes*	$\langle\sigma\rangle$, *3Cs.1.1*
3	C_3	4	1	1, 3	*no*	*no*	U
4	V_4	6	2	1, 1, 2	*yes*	*yes*	C_s, *3Cs*
4	C_4	3	0	2, 2	*no*	*no*	$\langle J\rangle$
6	S_3	4	1	1, 3	*yes*	*yes*	*3B.1.1*
6	S_3	4	1	1, 3	*yes*	*yes*	*3B.1.2*
6	C_6	4	1	1, 3	*no*	*no*	$\{\pm I\} \times \mathrm{U}$
8	C_8	3	0	4	*yes*	*no*	C_{ns}, *3Cn*
8	D_4	3	0	2, 2	*yes*	*yes*	N_s, *3Ns*
8	Q_8	1	0	4	*no*	*no*	Q_8
12	D_6	4	1	1, 3	*yes*	*yes*	B, *3B*
16	SD_{16}	3	0	4	*yes*	*yes*	N_{ns}, *3Nn*
24	$\mathrm{SL}_2(\mathbb{F}_3)$	1	0	4	*no*	*no*	$\mathrm{SL}_2(\mathbb{F}_3)$
48	$\mathrm{GL}_2(\mathbb{F}_3)$	1	0	4	*yes*	*yes*	$\mathrm{GL}_2(\mathbb{F}_3)$

In particular the subgroups with surjective determinant form 9 *conjugacy classes, and all of them except* $C_{ns}(\mathbb{F}_3)$ *contain an element of determinant* -1 *and trace* 0. *Every subgroup of order divisible by* 3 *either contains* $\mathrm{SL}_2(\mathbb{F}_3)$ *or stabilises a line of* $\mathbb{F}_3^2$ *(the case* $\ell = 3$ *of Theorem 1.57(a)).*

Proof. The table was obtained, and checked, by a complete computer enumeration of the subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$ (every subgroup is generated by two elements, so it suffices to close up all pairs). The rows that the paper needs are proved in Proposition 1.46(iv), Proposition 1.48, Proposition 1.62, Proposition 1.63, Proposition 1.64, Theorem 1.65 and Proposition 1.68. We prove the last statement. Let $3 \mid \#H$. A Sylow 3-subgroup of H has order 3, so it is one of the groups U_L (Proposition 1.48(v)). If it is normal in H, then every $h \in H$ satisfies $h\mathrm{U}_L h^{-1} = \mathrm{U}_L$; since $h\mathrm{U}_L h^{-1} = \mathrm{U}_{hL}$ fixes exactly the line hL, we get $hL = L$, and H stabilises L. Otherwise $n_3(H) > 1$, $n_3(H) \equiv 1 \pmod 3$, and $n_3(H) \le 4$ (there are only four subgroups of order 3 in $\mathrm{GL}_2(\mathbb{F}_3)$); so $n_3(H) = 4$, H contains all four U_L, hence all 8 elements of order 3, hence $\mathrm{SL}_2(\mathbb{F}_3)$ by Proposition 1.48(v). □

Proposition 1.62 ($\mathrm{SL}_2(\mathbb{F}_3)$ and Q_8)**.** *(i)* $\mathrm{SL}_2(\mathbb{F}_3)$ *has order* 24, *and* 1, 1, 8, 6, 8 *elements of orders* 1, 2, 3, 4, 6; $-I$ *is its unique element of order* 2.

(ii) The 8 *elements of* $\mathrm{SL}_2(\mathbb{F}_3)$ *of order dividing* 4 *form the subgroup* Q_8 *of Convention 1.60. It is the unique Sylow* 2*-subgroup of* $\mathrm{SL}_2(\mathbb{F}_3)$, *it is normal in* $\mathrm{GL}_2(\mathbb{F}_3)$, *and it is isomorphic to the quaternion group, with* $i = J$, $j = \left(\begin{smallmatrix} 1 & -1 \\ -1 & -1 \end{smallmatrix}\right)$, $k = ij = \left(\begin{smallmatrix} -1 & -1 \\ -1 & 1 \end{smallmatrix}\right)$.

(iii) $\mathrm{SL}_2(\mathbb{F}_3) = Q_8 \rtimes \mathrm{U} \simeq Q_8 \rtimes C_3$, *where* u *permutes* i, j, k *cyclically:* $uiu^{-1} = k$, $uku^{-1} = j$, $uju^{-1} = i$.

(iv) $[\mathrm{SL}_2(\mathbb{F}_3), \mathrm{SL}_2(\mathbb{F}_3)] = Q_8$, *and* $\mathrm{SL}_2(\mathbb{F}_3)$ *has no subgroup of order* 12.

(v) $\mathrm{SL}_2(\mathbb{F}_3)/\{\pm I\} \simeq A_4$, $\mathrm{SL}_2(\mathbb{F}_3) \not\simeq S_4$, *and* $\mathrm{GL}_2(\mathbb{F}_3)/Q_8 \simeq S_3$.

(vi) Q_8 *acts transitively on the four lines of* $\mathbb{F}_3^2$; *its image in* S_4 *is the normal subgroup* V_4.

Proof. (i) The classes of $\mathrm{GL}_2(\mathbb{F}_3)$ of determinant 1 are those of $I, -I, u, J, -u$ (Proposition 1.59), of sizes 1, 1, 8, 6, 8; and Proposition 1.41(iv). (ii) The elements of order dividing 4 are $\pm I$ and

the six elements of the class of J, which are the six matrices of trace 0 and determinant 1; these are $\pm J$, $\pm\left(\begin{smallmatrix}1&1\\1&-1\end{smallmatrix}\right)$, $\pm\left(\begin{smallmatrix}1&-1\\-1&-1\end{smallmatrix}\right)$, the set Q_8 of Convention 1.60. A Sylow 2-subgroup P of $\mathrm{SL}_2(\mathbb{F}_3)$ has order 8, and its elements have order dividing 8, hence dividing 4 (there is no element of order 8 in $\mathrm{SL}_2(\mathbb{F}_3)$); so $P \subseteq Q_8$, and $P = Q_8$ by counting. Hence Q_8 is a subgroup, and the unique Sylow 2-subgroup. It is a union of conjugacy classes of $\mathrm{GL}_2(\mathbb{F}_3)$ (conjugation preserves order and determinant), hence normal in $\mathrm{GL}_2(\mathbb{F}_3)$. With $i = J$ and $j = \left(\begin{smallmatrix}1&-1\\-1&-1\end{smallmatrix}\right)$ one computes $k = ij = \left(\begin{smallmatrix}-1&-1\\-1&1\end{smallmatrix}\right)$, $ji = \left(\begin{smallmatrix}1&1\\1&-1\end{smallmatrix}\right) = -k$; so Q_8 is non-abelian with unique involution $-I$, and is the quaternion group by Proposition 1.21(v). (iii) Q_8 is normal, $\mathrm{U} \cap Q_8 = 1$ (orders 3 and 8), and $\#Q_8\mathrm{U} = 24$; apply Proposition 1.15(i). Direct computation with $u^{-1} = \left(\begin{smallmatrix}1&-1\\0&1\end{smallmatrix}\right)$ gives $uJu^{-1} = \left(\begin{smallmatrix}-1&2\\-1&1\end{smallmatrix}\right) = \left(\begin{smallmatrix}-1&-1\\-1&1\end{smallmatrix}\right) = k$ and $uku^{-1} = \left(\begin{smallmatrix}-2&2\\-1&2\end{smallmatrix}\right) = \left(\begin{smallmatrix}1&-1\\-1&-1\end{smallmatrix}\right) = j$, and then, as $j = ki$, $uju^{-1} = (uku^{-1})(uiu^{-1}) = jk = i$. (iv) $\mathrm{SL}_2(\mathbb{F}_3)/Q_8 \simeq C_3$ is abelian, so the commutator subgroup lies in Q_8. It contains $uiu^{-1}i^{-1} = ki^{-1} = -ki = -j$, hence $j = (-j)^{-1}$, and, being normal, the conjugates $uju^{-1} = i$ and $uiu^{-1} = k$; so it is Q_8. A subgroup of order 12 would have index 2, so it would contain every square of $\mathrm{SL}_2(\mathbb{F}_3)$: the 8 elements of order 3 (each is the square of its own square, $x = x^4 = (x^2)^2$), $-I = J^2$ and therefore the 8 elements $-u = (-I)u$; that is at least 18 elements, a contradiction. (v) The first isomorphism is Theorem 1.52(i). S_4 has nine elements of order 2 (six transpositions, three double transpositions) and $\mathrm{SL}_2(\mathbb{F}_3)$ has one. $\mathrm{GL}_2(\mathbb{F}_3)/Q_8$ has order 6; it is generated by the images of u (order 3) and σ (order 2, as $\sigma \notin Q_8$), with $\sigma u\sigma^{-1} = u^{-1}$; so it is $D_3 \simeq S_3$ by Proposition 1.19(i),(iv). (vi) J acts by $x \mapsto -1/x$, that is as $(\infty\ 0)(1\ -1)$; j acts by $x \mapsto (1-x)/(1+x)$, that is as $(\infty\ -1)(0\ 1)$; their product k acts as $(\infty\ 1)(0\ -1)$. So the image of Q_8 is $\{1, (\infty\,0)(1\,{-1}), (\infty\,1)(0\,{-1}), (\infty\,{-1})(0\,1)\}$, the normal Klein four-group of S_4, which is transitive. □

Proposition 1.63 (The normaliser of the split Cartan subgroup). *(i) The group $N_s(\mathbb{F}_3) = \{\pm I, \pm J, \pm\sigma, \pm w\}$, which equals $\langle J, \sigma\rangle$, has order 8 and is dihedral, $N_s(\mathbb{F}_3) \simeq D_4$, with $r = J$, $s = \sigma$. Its elements of determinant -1 are exactly $\pm\sigma$, $\pm w$; they have trace 0 and order 2.*

(ii) It is the normaliser of $C_s(\mathbb{F}_3)$ and the stabiliser of the pair of lines $\{\infty, 0\}$; it has 3 conjugates, one for each partition of the four lines into two pairs.

(iii) Its determinant-one subgroup is $N_s(\mathbb{F}_3) \cap \mathrm{SL}_2(\mathbb{F}_3) = \langle J\rangle \simeq C_4$, cyclic, generated by J and also by $J^{-1} = -J = \left(\begin{smallmatrix}0&-1\\1&0\end{smallmatrix}\right)$.

(iv) Its orbits on the four lines are $\{\infty, 0\}$ (the two lines of the Cartan subgroup) and $\{1, -1\}$ (the other two), each of size 2; $\langle J\rangle$ has the same two orbits.

(v) $N_s(\mathbb{F}_3)$ stabilises no line of $\mathbb{F}_3^2$ and no line of $\overline{\mathbb{F}}_3^2$. The group $\langle J\rangle$ stabilises no line of $\mathbb{F}_3^2$, but stabilises the two lines of $\mathbb{F}_9^2$ spanned by $(i, 1)$ and $(-i, 1)$, where $i \in \mathbb{F}_9$, $i^2 = -1$; these are its eigenlines, with eigenvalues $-i$ and i respectively, and σ interchanges them.

(vi) Its image in $\mathrm{PGL}_2(\mathbb{F}_3) \simeq S_4$ is the non-normal Klein four-group generated by the transpositions $(\infty\,0)$ and $(1\,{-1})$.

(vii) $N_s(\mathbb{F}_3)$ is contained, with index 2, in the Sylow 2-subgroup $N_{ns}(\mathbb{F}_3)$.

Proof. (i) $C_s(\mathbb{F}_3) = \{\pm I, \pm\sigma\}$, and $wC_s(\mathbb{F}_3) = \{\pm w, \pm w\sigma\} = \{\pm w, \pm J\}$ (as $w\sigma = \left(\begin{smallmatrix}0&-1\\1&0\end{smallmatrix}\right) = -J$). So $N_s(\mathbb{F}_3) = \{\pm I, \pm J, \pm\sigma, \pm w\}$. Now J has order 4, σ order 2, $\sigma J\sigma^{-1} = \left(\begin{smallmatrix}0&-1\\1&0\end{smallmatrix}\right) = J^{-1}$, and

$\langle J,\sigma\rangle \subseteq N_s(\mathbb{F}_3)$ has order at least 8 (it contains $\langle J\rangle$ and $\sigma \notin \langle J\rangle$); so $N_s(\mathbb{F}_3) = \langle J,\sigma\rangle \simeq D_4$ by Proposition 1.19(i). The determinants of $\pm I, \pm J$ are 1 and those of $\pm\sigma, \pm w$ are -1; the latter have trace 0 and square to I. (ii) is Proposition 1.55(i) (here $\infty = [e_1]$ and $0 = [e_2]$). The stabiliser of the 2-subset $\{\infty, 0\}$ also stabilises its complement $\{1, -1\}$, and by (iv) $N_s(\mathbb{F}_3)$ stabilises no other 2-subset. $\mathrm{GL}_2(\mathbb{F}_3)$ is transitive on the six 2-subsets (Proposition 1.44(v)), and $gN_s(\mathbb{F}_3)g^{-1}$ is the stabiliser of $g\{\infty, 0\}$; so the conjugates correspond to the three partitions into two pairs. (iii) The determinant-one elements are $\pm I, \pm J$. (iv) σ acts by $x \mapsto -x$, as $(1\,{-1})$; w by $x \mapsto 1/x$, as $(\infty\,0)$ (note $1/(-1) = -1$); J by $x \mapsto -1/x$, as $(\infty\,0)(1\,{-1})$. (v) A stable line of $\mathbb{F}_3^2$ would be a fixed point on the four lines, and there is none by (iv). Over $\overline{\mathbb{F}}_3$: $[N_s(\mathbb{F}_3), N_s(\mathbb{F}_3)] \ni J\sigma J^{-1}\sigma^{-1} = J \cdot J = -I$, so the commutator subgroup contains an element of order 2 and is not a 3-group; apply Lemma 1.50(ii). For $\langle J\rangle$: $X^2 + 1$ has no root in $\mathbb{F}_3$, so J has no eigenline over $\mathbb{F}_3$. Over $\mathbb{F}_9$, $J\binom{x}{y} = \binom{y}{-x}$, and $\binom{\lambda}{1}$ is an eigenvector, with eigenvalue $-\lambda$, iff $\lambda^2 = -1$; so the eigenlines are spanned by $(i, 1)$ and $(-i, 1)$, and they are stable under $\langle J\rangle$. Finally $\sigma\binom{i}{1} = \binom{i}{-1} = -\binom{-i}{1}$. (vi) follows from (iv). (vii) $J = m_{-i} \in C_{ns}(\mathbb{F}_3)$ and $\sigma \in N_{ns}(\mathbb{F}_3)$, so $\langle J,\sigma\rangle \subseteq N_{ns}(\mathbb{F}_3)$, which has order 16 and is a Sylow 2-subgroup by Proposition 1.64(iii). □

Proposition 1.64 (The normaliser of the nonsplit Cartan subgroup)**.** *(i) The group $C_{ns}(\mathbb{F}_3)$ is cyclic of order 8, generated by $a = \left(\begin{smallmatrix}1 & -1\\ 1 & 1\end{smallmatrix}\right) = m_{1+i}$; $a^2 = J$ and $a^4 = -I$.*

(ii) $N_{ns}(\mathbb{F}_3) = \langle a,\sigma\rangle$ has order 16, $\sigma a\sigma^{-1} = a^3$ (conjugation by σ is the Frobenius $c \mapsto c^3$ of $\mathbb{F}_9$), and $N_{ns}(\mathbb{F}_3) \simeq SD_{16}$; it has $1, 5, 6, 4$ elements of orders $1, 2, 4, 8$.

(iii) It is a Sylow 2-subgroup of $\mathrm{GL}_2(\mathbb{F}_3)$, with 3 conjugates.

(iv) Its determinant-one subgroup is Q_8: the four elements $\pm I, \pm J$ of $C_{ns}(\mathbb{F}_3) \cap \mathrm{SL}_2(\mathbb{F}_3)$ and the four elements $m_c\sigma$ with $N(c) = -1$. Its three subgroups of index 2 are $C_{ns}(\mathbb{F}_3) \simeq C_8$, $N_s(\mathbb{F}_3) = \langle a^2,\sigma\rangle \simeq D_4$ and $Q_8 = \langle a^2, a\sigma\rangle$.

(v) Its elements of determinant -1 and trace 0 are the four involutions $m_c\sigma$ with $N(c) = 1$, namely $\pm\sigma$, $\pm w$ (the same four as in $N_s(\mathbb{F}_3)$). $C_{ns}(\mathbb{F}_3)$ contains none: its elements of determinant -1 are its four elements of order 8, of trace ± 1.

(vi) $C_{ns}(\mathbb{F}_3)$, hence $N_{ns}(\mathbb{F}_3)$, acts transitively on the four lines, $C_{ns}(\mathbb{F}_3)/\{\pm I\} \simeq C_4$ simply transitively; the image of $N_{ns}(\mathbb{F}_3)$ in S_4 is a Sylow 2-subgroup, isomorphic to D_4. Q_8 is also transitive.

Proof. (i) $C_{ns}(\mathbb{F}_3) \simeq \mathbb{F}_9^\times$ is cyclic of order 8 (Proposition 1.55(ii)). In $\mathbb{F}_9$, $(1+i)^2 = 2i = -i$ and $(1+i)^4 = (-i)^2 = -1$, so $1+i$ has order 8; and $m_{1+i} = I + m_i = I - J = a$, $a^2 = m_{-i} = J$, $a^4 = -I$. (ii) By Proposition 1.55(iii), $\sigma a\sigma^{-1} = m_{1-i}$ and $(1+i)^3 = (1+i)(-i) = 1 - i$; so $\sigma a\sigma^{-1} = a^3$. The group $\langle a,\sigma\rangle$ contains $C_{ns}(\mathbb{F}_3)$ and σ, so it is $N_{ns}(\mathbb{F}_3)$, of order 16; by Proposition 1.23(iv) it is SD_{16}, and (ii) of that proposition gives the element orders. (iii) $48 = 16 \cdot 3$. The number of conjugates is $n_2 \in \{1, 3\}$, and $N_{ns}(\mathbb{F}_3)$ is not normal: its elements are the matrices $\left(\begin{smallmatrix}a & -b\\ b & a\end{smallmatrix}\right)$ and $m_c\sigma = \left(\begin{smallmatrix}a & b\\ b & -a\end{smallmatrix}\right)$, and $u\sigma u^{-1} = \left(\begin{smallmatrix}1 & 1\\ 0 & -1\end{smallmatrix}\right)$ is of neither form. So $n_2 = 3$. (iv) $C_{ns} \cap \mathrm{SL}_2$ is the kernel of the norm, of order 4, which is $\langle a^2\rangle = \langle J\rangle$; in the other coset $\det(m_c\sigma) = -N(c)$, and $N(c) = -1$ for four values of c (Proposition 1.56(iv)). So the determinant-one subgroup has order 8; it is a 2-subgroup of $\mathrm{SL}_2(\mathbb{F}_3)$ of order 8, hence the Sylow 2-subgroup Q_8 (Proposition 1.62(ii)). The index-2 subgroups are those of Proposition 1.23(iii): $\langle a\rangle = C_{ns}(\mathbb{F}_3)$; $\langle a^2,\sigma\rangle = \langle J,\sigma\rangle = N_s(\mathbb{F}_3)$; and $\langle a^2, a\sigma\rangle$, which lies in $\mathrm{SL}_2(\mathbb{F}_3)$ ($\det a = \det\sigma = -1$) and has order 8, so it is Q_8. (v) The

elements $m_c\sigma$ have trace 0, and determinant -1 iff $N(c) = 1$, that is $c \in \{\pm 1, \pm i\}$; these give $\pm\sigma$ and $\pm J\sigma = \pm w$. In $C_{ns}(\mathbb{F}_3)$, $\det a = -1$ and $\det a^2 = 1$, so the elements of determinant -1 are the odd powers of a, the elements of order 8; a and $a^3 = m_{1-i}$ have trace $2 = -1$, and $a^5 = -a$, $a^7 = -a^3$ have trace 1. (vi) is Proposition 1.56(v) for $q = 3$, and the image has order $16/2 = 8$, a Sylow 2-subgroup of S_4, which is dihedral (Example 1.34(b)). For Q_8 see Proposition 1.62(vi). □

Theorem 1.65 (The three images)**.** *Let $H \leq \mathrm{GL}_2(\mathbb{F}_3)$ satisfy:*

(a) $\det(H) = \mathbb{F}_3^\times$*;*

(b) H stabilises no line of $\mathbb{F}_3^2$;

(c) H contains an element of determinant -1 and trace 0.

Then H is conjugate to exactly one of $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ and $N_s(\mathbb{F}_3)$, of orders 48, 16, 8. Their determinant-one subgroups $H \cap \mathrm{SL}_2(\mathbb{F}_3)$, of index 2, are $\mathrm{SL}_2(\mathbb{F}_3)$, Q_8 and $C_4 = \langle J \rangle$ respectively. The first two stabilise no line of $\overline{\mathbb{F}}_3^2$; the third is abelian and stabilises two lines of $\mathbb{F}_9^2$. The subgroup $C_{ns}(\mathbb{F}_3)$ satisfies (a) and (b) but not (c).

Proof. The three conditions are invariant under conjugation, and the three groups satisfy them: (a) and (c) because each contains σ; (b) because $\mathrm{GL}_2(\mathbb{F}_3)$ and $N_{ns}(\mathbb{F}_3)$ are transitive on the four lines and $N_s(\mathbb{F}_3)$ has two orbits of size 2 (Proposition 1.64(vi), Proposition 1.63(iv)). They have different orders, so H is conjugate to at most one of them.

Suppose first that $3 \mid \#H$. By Proposition 1.61 (last statement) and (b), $H \supseteq \mathrm{SL}_2(\mathbb{F}_3)$; by (a), H contains an element of determinant -1, so H has index at most 2 in $\mathrm{GL}_2(\mathbb{F}_3)$ and properly contains $\mathrm{SL}_2(\mathbb{F}_3)$, whence $H = \mathrm{GL}_2(\mathbb{F}_3)$.

Suppose now that $3 \nmid \#H$. Then $\#H$ divides 16, H is a 2-group, and by Theorem 1.33(ii) it is contained in a Sylow 2-subgroup, which is conjugate to $N_{ns}(\mathbb{F}_3)$. Replacing H by a conjugate we may assume $H \leq N_{ns}(\mathbb{F}_3)$. By (a), $H \cap \mathrm{SL}_2(\mathbb{F}_3)$ has index 2 in H; in particular $\#H \geq 2$.

- If $\#H = 16$, then $H = N_{ns}(\mathbb{F}_3)$.
- If $\#H = 8$, H is one of the three subgroups of index 2 of Proposition 1.64(iv). Q_8 fails (a), $C_{ns}(\mathbb{F}_3)$ fails (c) by Proposition 1.64(v), and $N_s(\mathbb{F}_3)$ satisfies all three. So $H = N_s(\mathbb{F}_3)$.
- If $\#H \in \{2, 4\}$, then by (c) H contains an element g of determinant -1 and trace 0, an involution with two eigenlines (characteristic polynomial $X^2 - 1$). Then $H \cap \mathrm{SL}_2(\mathbb{F}_3)$ has order $\#H/2 \leq 2$, so it is 1 or $\{\pm I\}$ ($-I$ being the only involution of $\mathrm{SL}_2(\mathbb{F}_3)$), and $H = (H \cap \mathrm{SL}_2(\mathbb{F}_3)) \cup g(H \cap \mathrm{SL}_2(\mathbb{F}_3))$ is $\{I, g\}$ or $\{\pm I, \pm g\}$. Both stabilise the eigenlines of g, contradicting (b).

So H is conjugate to $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ or $N_s(\mathbb{F}_3)$. The determinant-one subgroups are computed in Proposition 1.64(iv) and Proposition 1.63(iii). The commutator subgroups of $\mathrm{SL}_2(\mathbb{F}_3)$ and of Q_8 are Q_8 and $\{\pm I\}$ (Proposition 1.62(iv), Proposition 1.21(ii)), which are not 3-groups, so by Lemma 1.50(ii) these groups stabilise no line of $\overline{\mathbb{F}}_3^2$. The group $\langle J \rangle$ is cyclic and stabilises the two eigenlines of J in $\mathbb{F}_9^2$ (Proposition 1.63(v)). Finally $C_{ns}(\mathbb{F}_3)$ has surjective determinant and is transitive on the lines (Proposition 1.56(iii),(v)), but contains no element of determinant -1 and trace 0 (Proposition 1.64(v)). □

Corollary 1.66 (Orbit dichotomy)**.** *For H as in Theorem 1.65 the following are equivalent:*

(i) H *is conjugate to* $N_s(\mathbb{F}_3)$*;*

(ii) H *has two orbits, each of size* 2*, on the four lines of* $\mathbb{F}_3^2$*;*

(iii) H *is not transitive on the four lines;*

(iv) $H \cap \mathrm{SL}_2(\mathbb{F}_3)$ *is abelian;*

(v) $H \cap \mathrm{SL}_2(\mathbb{F}_3)$ *stabilises a line of* $\overline{\mathbb{F}}_3^2$*.*

Otherwise H *is transitive on the four lines.*

Proof. All five properties are invariant under conjugation, so by Theorem 1.65 we may take H to be one of the three standard models. For $N_s(\mathbb{F}_3)$, (ii) holds by Proposition 1.63(iv), (iv) because $\langle J \rangle$ is cyclic, and (v) by Proposition 1.63(v); (ii) implies (iii). For $\mathrm{GL}_2(\mathbb{F}_3)$ and $N_{ns}(\mathbb{F}_3)$, (ii) and (iii) fail because they are transitive, (iv) fails because $\mathrm{SL}_2(\mathbb{F}_3)$ and Q_8 are non-abelian, and (v) fails by Theorem 1.65. □

In the paper 1.67. The proof of Proposition prop:ns states that when $E[3]$ is irreducible the image H of $\bar{\rho}_{E,3}$ is conjugate to $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ or $N_s(\mathbb{F}_3)$, notes that the list is in [210], and derives it directly: "these are the subgroups with surjective determinant acting irreducibly on $\mathbb{F}_3^2$ that contain an element of determinant -1 and trace 0 (complex conjugation), the nonsplit Cartan subgroup itself being excluded by the last condition, and the list follows from these three properties by inspection of the subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$". Theorem 1.65 is that inspection, carried out. The three hypotheses hold for $H = \bar{\rho}_{E,3}(G_{\mathbb{Q}})$: (a) because $\det \bar{\rho}_{E,3} = \bar{\chi}_3$ is surjective onto $\mathbb{F}_3^\times$; (b) because irreducibility of $E[3]$ means that no line is stable; (c) because the image of complex conjugation c satisfies $\bar{\rho}(c)^2 = I$ and $\det \bar{\rho}(c) = \bar{\chi}_3(c) = -1$, so its eigenvalues are 1 and -1 and its trace is 0 (Chapter 11). As the paper says, the list holds with or without complex multiplication: none of (a), (b), (c) refers to it. The determinant-one subgroups are the paper's "$\mathrm{SL}_2(\mathbb{F}_3)$, the quaternion group Q_8 and the cyclic group C_4 of order 4". The paper's final sentence on the 3-division polynomial is Corollary 1.66(i)⇔(ii)⇔(iii): its four roots correspond to the four lines, the factors over $\mathbb{Q}$ correspond to the orbits of H (Chapter 5), and so it factors as two irreducible quadratics exactly in the $N_s(\mathbb{F}_3)$ case and is irreducible otherwise. The equivalence (i)⇔(v) is the group-theoretic half of "$\bar{\rho}_{E,3}$ is absolutely irreducible on $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$ unless its image is conjugate to the normaliser $N_s(\mathbb{F}_3)$ of a split Cartan subgroup of $\mathrm{GL}_2(\mathbb{F}_3)$"; the image of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$ is $H \cap \mathrm{SL}_2(\mathbb{F}_3)$ by Lemma 1.7(ii). The consequences $\bar{\rho}_{E,3} \otimes \mathbb{F}_9 \simeq \mathrm{Ind}\,\psi$ and $\bar{\rho}_{E,3} \simeq \bar{\rho}_{E,3} \otimes \chi_{-3}$ are representation theory (Chapter 4), and $h_3(E) = 1$ is Lemma lem:h0, proved in Chapter 11.

Proposition 1.68 (Determinant -1 and trace 0)**.** *Let* q *be odd and* $g \in \mathrm{GL}_2(\mathbb{F}_q)$*. Then* $\det g = -1$ *and* $\operatorname{tr} g = 0$ *if and only if the characteristic polynomial of* g *is* $X^2 - 1$*, if and only if* g *is conjugate to* $\sigma = \mathrm{diag}(1, -1)$*. Such an element has order* 2 *and fixes exactly two lines (its eigenlines); for* $q = 3$ *it swaps the other two. These elements form one conjugacy class of* $q(q+1)$ *elements. For* $q = 3$ *their numbers in the standard subgroups are:* $\mathrm{GL}_2(\mathbb{F}_3)$*:* 12*;* B*:* 6*;* N_s*:* 4*;* N_{ns}*:* 4*;* C_s*:* 2*;* C_{ns}*:* 0*;* $\mathrm{SL}_2(\mathbb{F}_3)$*:* 0*.*

Proof. The characteristic polynomial is $X^2 - \operatorname{tr}(g)X + \det g$. A matrix with characteristic polynomial $X^2 - 1$ is not scalar (a scalar λI has $(X - \lambda)^2$, and $1 \neq -1$), so it is conjugate to σ by Lemma 1.42. Its eigenvalues 1, -1 are distinct, which gives the order and the two eigenlines. For $q = 3$, σ acts as the transposition $(1\,{-1})$ (Proposition 1.59). The centraliser of σ is C_s, of

order $(q-1)^2$, so the class has $q(q-1)^2(q+1)/(q-1)^2 = q(q+1)$ elements. In $\mathrm{B}(\mathbb{F}_3)$: $\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)$ with $a+d=0$ and $ad=-1$ means $(a,d) = \pm(1,-1)$ with b arbitrary, 6 elements. The counts in N_s, N_{ns} and C_{ns} are Proposition 1.63(i) and Proposition 1.64(v); in C_s they are $\pm\sigma$; and SL_2 has no element of determinant -1. □

Example 1.69 (Sutherland's labels at $\ell = 3$)**.** The paper names mod 3 images by the labels of [191]. Because a transposition (row vectors versus column vectors) interchanges some of the matrix descriptions, we define each label by an intrinsic property of the action on $E[3]$, which is convention-free; the groups are then the standard models up to conjugacy, and the orders are those of Proposition 1.61.

- **3Cs.1.1**: $\{I, \sigma\}$, of order 2: $E[3] \simeq \mathbb{Z}/3 \oplus \mu_3$, that is, a basis in which $G_{\mathbb{Q}}$ acts trivially on the first vector and by the determinant $\bar{\chi}_3$ on the second. (It is a subgroup of the split Cartan subgroup, not the split Cartan subgroup itself.)
- **3Cs**: $C_s(\mathbb{F}_3)$, of order 4: the full group of matrices stabilising each of two distinct lines.
- **3B.1.1**: $\{\left(\begin{smallmatrix} 1 & * \\ 0 & * \end{smallmatrix}\right)\}$, of order 6: a fixed nonzero vector, that is, a rational point of order 3.
- **3B.1.2**: $\{\left(\begin{smallmatrix} * & * \\ 0 & 1 \end{smallmatrix}\right)\}$, of order 6: a stable line, on which the group acts by the determinant, with trivial action on the quotient.
- **3B**: $\mathrm{B}(\mathbb{F}_3)$, of order 12: the full stabiliser of a line; a stable line means a rational 3-isogeny.
- **3Ns**: $N_s(\mathbb{F}_3)$, of order 8. **3Nn**: $N_{ns}(\mathbb{F}_3)$, of order 16.
- **3Cn**: $C_{ns}(\mathbb{F}_3)$, of order 8, in the same naming scheme. It contains no element of determinant -1 and trace 0 (Proposition 1.68), so it is never the mod 3 image of an elliptic curve over $\mathbb{Q}$ (Chapter 11).
- The surjective image $\mathrm{GL}_2(\mathbb{F}_3)$ carries no proper label.

These are the nine conjugacy classes of subgroups with surjective determinant in Proposition 1.61. The table there shows that 3B.1.1 and 3B.1.2 are not conjugate in $\mathrm{GL}_2(\mathbb{F}_3)$: they are distinguished by the existence of a nonzero fixed vector, which is the intrinsic property above. Which images occur for elliptic curves over $\mathbb{Q}$ is [210]; see Chapter 11.

In the paper 1.70. Section sec:anomaly and Remark rem:ns concern the curves with image 3Ns, that is, H conjugate to $N_s(\mathbb{F}_3)$. By Corollary 1.66 these are exactly the curves (with $E[3]$ irreducible) whose 3-division polynomial factors as two quadratics, which is the intrinsic description of the label 3Ns that Section sec:data of the paper uses (Chapter 22). Section sec:eis and Conjecture conj:eis use the Borel-type labels: a rational 3-isogeny means image in a Borel subgroup (Proposition 1.46(iii)); a rational point of order 3 means image in 3B.1.1; and $E[3] \simeq \mathbb{Z}/3 \oplus \mu_3$ means image 3Cs.1.1, the subgroup of order 2 of the split Cartan subgroup that fixes a nonzero vector.

Proposition 1.71 (Images in S_4)**.** *Under* $\mathrm{PGL}_2(\mathbb{F}_3) \simeq S_4$ *(Theorem 1.52(i)) the standard subgroups map as follows:*

subgroup	GL_2	SL_2	N_{ns}	Q_8	N_s	C_{ns}	C_s	$\langle J \rangle$	B	U
image	S_4	A_4	D_4	$V_4 \trianglelefteq S_4$	$V_4 \not\trianglelefteq S_4$	C_4	$\langle(1\,{-1})\rangle$	$\langle(\infty\,0)(1\,{-1})\rangle$	S_3	A_3
order	24	12	8	4	4	4	2	2	6	3

Here D_4 is a Sylow 2-subgroup of S_4, S_3 is the stabiliser of ∞, and A_3 is generated by the 3-cycle $(0\,1\,{-1})$.

Proof. The image of K is $K/(K\cap\{\pm I\})$, which gives the orders. GL_2 and SL_2: Theorem 1.52(i). N_{ns}: Proposition 1.64(vi). Q_8: Proposition 1.62(vi). N_s and $\langle J\rangle$: Proposition 1.63(iv),(vi). C_{ns} is cyclic of order 8 with $a^4=-I$, so its image is cyclic of order 4. $C_s=\{\pm I,\pm\sigma\}$ maps onto $\langle(1\,{-1})\rangle$. B: Proposition 1.46(iv). u acts by $x\mapsto x+1$, that is as $(0\,1\,{-1})$, fixing ∞. □

Example 1.72 ($\mathrm{GL}_2(\mathbb{F}_5)$ and $\mathrm{GL}_2(\mathbb{F}_7)$)**.** For $q=5$ and $q=7$ (with $\varepsilon=2$ and $\varepsilon=3$, non-squares modulo 5 and 7) the formulas of Proposition 1.43, Proposition 1.46 and Proposition 1.56 give:

q	GL_2	SL_2	PGL_2	PSL_2	B	C_s	N_s	C_{ns}	N_{ns}	$\#\mathbb{P}^1$
5	480	120	120	60	80	16	32	24	48	6
7	2016	336	336	168	252	36	72	48	96	8

(all checked by enumeration). By Theorem 1.52, $\mathrm{PGL}_2(\mathbb{F}_5)\simeq S_5$, $\mathrm{PSL}_2(\mathbb{F}_5)\simeq A_5$, and $\mathrm{PSL}_2(\mathbb{F}_7)\simeq\mathrm{GL}_3(\mathbb{F}_2)$ is simple. At $\ell=5$ the exceptional case $\bar G\simeq S_4$ of Theorem 1.57 occurs inside $\mathrm{PGL}_2(\mathbb{F}_5)\simeq S_5$ and contains the image of $N_s(\mathbb{F}_5)$ (Warning 1.58). The coincidence that makes $\ell=3$ special in the paper is not group-theoretic: for $\ell=3$ the reduction $\bar\chi_3$ of the cyclotomic character equals the quadratic character χ_{-3}, while for $\ell\geq 5$ the character $\bar\chi_\ell$ has order $\ell-1>2$ and differs from χ_{ℓ^*} (Theorem 1.4(iv)). This is why Lemma lem:h0 gives $h_\ell(E)=0$ for $\ell\geq 5$ (Chapter 4, Chapter 11).

1.7 Inverse limits and profinite groups

The Galois groups of the paper, $G_{\mathbb{Q}}=\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$, the local groups $G_{\mathbb{Q}_p}$ and the inertia groups I_p, are infinite, and the representations $\rho_{E,\ell}$ take values in $\mathrm{GL}_2(\mathbb{Z}_\ell)$. Both are profinite groups: inverse limits of finite groups, with a compact topology in which "continuous" means "factors through a finite quotient at each finite level". This section gives the definitions and the facts used in the paper: a continuous representation modulo ℓ^k factors through a finite quotient (Lemma lem:h0, Lemma lem:tamagawa-exp), a pro-p group has no nontrivial continuous image of order prime to p (the wild inertia in Lemma lem:tamfactor), and the kernel of $\mathrm{GL}_2(\mathbb{Z}_3)\to\mathrm{GL}_2(\mathbb{F}_3)$ is torsion-free (Lemma lem:IV). The infinite Galois theory itself is Chapter 5.

Definition 1.73 (Inverse limits; profinite groups)**.** An *inverse system* of groups (indexed by $\mathbb{N}$) is a sequence of groups G_n, $n\geq 1$, with homomorphisms $\pi_n\colon G_{n+1}\to G_n$. Its *inverse limit* is

$$\varprojlim G_n=\Big\{(g_n)_{n\geq 1}\in\prod_{n\geq 1}G_n:\ \pi_n(g_{n+1})=g_n\ \text{for all } n\Big\},$$

a subgroup of the product, with projections $p_n\colon\varprojlim G_n\to G_n$. When the G_n are finite, each is given the discrete topology, $\prod G_n$ the product topology and $\varprojlim G_n$ the subspace topology. A *profinite group* is a topological group isomorphic, as a topological group, to such an inverse limit of finite groups. A *pro-p group* is an inverse limit of finite p-groups.

An element of $\varprojlim G_n$ is a sequence of compatible approximations, one at each finite level. For $G_n=\mathbb{Z}/3^n$ with the reduction maps, the sequence $(2,8,26,80,\dots)$, with n-th term 3^n-1, is compatible ($3^{n+1}-1\equiv 3^n-1\pmod{3^n}$) and is the element -1 of $\mathbb{Z}_3$; the sequence $(1,4,13,40,\dots)$ with n-th term $1+3+\cdots+3^{n-1}=(3^n-1)/2$ is compatible as well, and twice it is -1, so it is

$-1/2 \in \mathbb{Z}_3$ (Example 1.76). The topology says that two elements are close when they agree at many levels: the sets gU_n of elements agreeing with g in the first n coordinates, $n \geq 1$, form a basis of open neighbourhoods of g (Proposition 1.77(i)). A homomorphism to a finite group is continuous exactly when it only depends on finitely many coordinates (Proposition 1.77(iii)), which is the meaning of continuity for Galois representations modulo ℓ^k.

Remark 1.74. For Galois groups one needs inverse systems indexed by a *directed* set $(I, \leq)$ (a partial order in which any two elements have an upper bound), with maps $\pi_{ij} \colon G_j \to G_i$ for $i \leq j$ satisfying $\pi_{ii} = \mathrm{id}$ and $\pi_{ij}\pi_{jk} = \pi_{ik}$; the limit is the set of $(g_i) \in \prod_i G_i$ with $\pi_{ij}(g_j) = g_i$. Everything below holds in this generality with the same proofs, replacing "n large" by "i large in I". For example $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) = \varprojlim \mathrm{Gal}(K/\mathbb{Q})$ over the finite Galois extensions $K/\mathbb{Q}$ inside $\overline{\mathbb{Q}}$, ordered by inclusion (Chapter 5).

Proposition 1.75. *Let (G_n, π_n) be an inverse system of finite groups and $G = \varprojlim G_n$.*

(i) (Universal property) For every group H with homomorphisms $f_n \colon H \to G_n$ such that $\pi_n \circ f_{n+1} = f_n$, there is a unique homomorphism $f \colon H \to G$ with $p_n \circ f = f_n$ for all n.

(ii) G is a closed subgroup of $\prod G_n$, and a Hausdorff topological group.

(iii) G is compact.

Proof. (i) Put $f(h) = (f_n(h))_n$, which lies in G by the compatibility; it is a homomorphism, and it is the only map with $p_n \circ f = f_n$. (ii) For each n the set $\{(g_m) : \pi_n(g_{n+1}) = g_n\}$ is the preimage of the closed subset $\{(x, y) : \pi_n(x) = y\}$ of the discrete space $G_{n+1} \times G_n$ under the continuous projection; so it is closed, and G is the intersection of these closed sets. Multiplication and inversion are continuous coordinatewise, hence continuous on the product and on G. A product of Hausdorff spaces is Hausdorff. (iii) By Tychonoff's theorem a product of compact spaces is compact (we do not prove this; see [139, Theorem 37.3]); finite discrete spaces are compact, and a closed subset of a compact space is compact. □

Example 1.76 (The p-adic integers)**.** Let p be a prime. The rings $\mathbb{Z}/p^n$ with the reduction maps form an inverse system, and $\mathbb{Z}_p = \varprojlim \mathbb{Z}/p^n$ is a ring (the operations being coordinatewise) and a compact topological group; its analysis, as the completion of $\mathbb{Z}$ for the p-adic absolute value, is Chapter 7.

(a) $x = (x_n) \in \mathbb{Z}_p$ is a unit if and only if $x_1 \neq 0$ in $\mathbb{Z}/p$; and $\mathbb{Z}_p^\times = \varprojlim (\mathbb{Z}/p^n)^\times$. Indeed, if $x_1 \neq 0$, every x_n is prime to p, hence a unit of $\mathbb{Z}/p^n$, and the inverses x_n^{-1} are compatible (inverses are unique), giving x^{-1}; conversely x_1 is a unit if x is.

(b) The kernel of $\mathbb{Z}_p \to \mathbb{Z}/p^n$ is $p^n\mathbb{Z}_p$. If $x_n = 0$, then for every k the element $x_{n+k} \in \mathbb{Z}/p^{n+k}$ is divisible by p^n, $x_{n+k} = p^n y_k$ with y_k well defined in $\mathbb{Z}/p^k$, and the y_k are compatible, so $x = p^n y$. The converse is clear.

(c) $\mathbb{Z}_p$ is torsion-free. If $mx = 0$ with $m \geq 1$ and $v = v_p(m)$, then $mx_{n+v} = 0$ in $\mathbb{Z}/p^{n+v}$. Write $m = p^v m'$; as m' is prime to p it is invertible modulo p^{n+v}, so $p^v x_{n+v} = 0$ in $\mathbb{Z}/p^{n+v}$, that is p^{n+v} divides p^v times a representative of x_{n+v}, so $p^n \mid x_{n+v}$. Hence $x_n = x_{n+v} \bmod p^n = 0$ for every n. (By contrast every element of each finite level $\mathbb{Z}/p^n$ is torsion; the point is that x_n is forced to vanish by looking at the deeper level $n + v$.)

(d) The open subgroups of $\mathbb{Z}_p$ are the $p^n\mathbb{Z}_p$, $n \geq 0$. By Proposition 1.77(i),(ii) (proved below) an open subgroup V contains some $p^n\mathbb{Z}_p$ and corresponds to a subgroup of $\mathbb{Z}_p/p^n\mathbb{Z}_p \simeq \mathbb{Z}/p^n$, which is $p^k\mathbb{Z}/p^n$ for some $k \leq n$ (Theorem 1.4(i)); so $V = p^k\mathbb{Z}_p$.

(e) Let $\widehat{\mathbb{Z}} = \varprojlim_n \mathbb{Z}/n!$; every $\mathbb{Z}/m$ is a quotient of $\widehat{\mathbb{Z}}$ (as $m \mid n!$ for $n \geq m$). By Proposition 1.13 (in its ring form, Chapter 2) $\mathbb{Z}/n! \simeq \prod_p \mathbb{Z}/p^{v_p(n!)}$, compatibly in n, and taking limits gives $\widehat{\mathbb{Z}} \simeq \prod_p \mathbb{Z}_p$.

(f) (Foretaste.) For a prime ℓ and a field K of characteristic $\neq \ell$ containing all ℓ-power roots of unity, $\mathbb{Z}_\ell(1) = \varprojlim \mu_{\ell^n}(K)$, with the maps $\zeta \mapsto \zeta^\ell$. Choosing a compatible system of generators ζ_{ℓ^n} ($\zeta_{\ell^{n+1}}^\ell = \zeta_{\ell^n}$) gives an isomorphism $\mathbb{Z}_\ell \simeq \mathbb{Z}_\ell(1)$ of groups, but the Galois group acts on $\mathbb{Z}_\ell(1)$ through the cyclotomic character χ_ℓ (Chapter 5, Chapter 7). The paper's coefficient modules $\mathbb{Z}_\ell$, $T_\ell E$, $\mathbb{Z}_\ell(1)$ and $\mathbb{Q}_\ell/\mathbb{Z}_\ell = \varinjlim \ell^{-n}\mathbb{Z}_\ell/\mathbb{Z}_\ell$ are all built from these.

Proposition 1.77 (Profinite groups)**.** *Let $G = \varprojlim G_n$ be profinite, and $U_n = \ker(p_n \colon G \to G_n)$.*

(i) The U_n are open normal subgroups of finite index, $U_{n+1} \subseteq U_n$, $\bigcap_n U_n = 1$, and they form a basis of open neighbourhoods of 1.

(ii) A subgroup of G is open if and only if it is closed of finite index.

(iii) A homomorphism f from G to a finite group F that is continuous (F discrete) has open kernel, and factors through G/U_n for some n; if the maps p_n are surjective, f factors through G_n.

(iv) Closed subgroups of G, and quotients of G by closed normal subgroups, are profinite. The image of a continuous homomorphism from G to a Hausdorff topological group (such as $\mathrm{GL}_2(\mathbb{Z}_\ell)$) is closed.

(v) A topological group is profinite (for an inverse system indexed by a directed set, Remark 1.74) if and only if it is compact, Hausdorff and totally disconnected.

(vi) Closed subgroups and quotients by closed normal subgroups of a pro-p group are pro-p; every continuous homomorphism from a pro-p group to a finite group of order prime to p is trivial.

Proof. (i) $U_n = p_n^{-1}(1)$ is open (p_n is continuous and G_n discrete), normal, and of index at most $\#G_n$. If $g \in U_{n+1}$, then $g_n = \pi_n(g_{n+1}) = 1$; so $U_{n+1} \subseteq U_n$, and likewise $g \in U_n$ implies $g_m = 1$ for all $m \leq n$. An element of all U_n is 1. A basic open neighbourhood of 1 in the product restricts finitely many coordinates, say $g_m \in S_m$ for $m \leq n$, with $1 \in S_m$; it contains U_n by the previous remark. (ii) If V is an open subgroup, its complement is the union of the open cosets $gV \neq V$, so V is closed; the cosets of V form a disjoint open cover of the compact space G, so there are finitely many. Conversely, if V is closed of finite index, its complement is a finite union of closed cosets, so V is open. (iii) $\ker f = f^{-1}(1)$ is open, so it contains some U_n by (i), and f factors through G/U_n, which is isomorphic to $p_n(G) \leq G_n$ by the first isomorphism theorem, and to G_n if p_n is surjective. (iv) Let $H \leq G$ be closed and $H_n = p_n(H)$; the H_n form an inverse system (as $\pi_n(p_{n+1}(h)) = p_n(h)$, π_n maps H_{n+1} into H_n), and $h \mapsto (p_n(h))$ is a continuous injective homomorphism $H \to \varprojlim H_n$ (injective as $\bigcap U_n = 1$). It is surjective: let (h_n) be compatible, and choose $x_n \in H$ with $h_n = p_n(x_n)$. The sets $C_n = H \cap x_n U_n$ are closed (a coset of the open

subgroup U_n is closed, its complement being a union of cosets) and nonempty ($x_n \in C_n$). They are decreasing: $p_n(x_{n+1}) = \pi_n(p_{n+1}(x_{n+1})) = \pi_n(h_{n+1}) = h_n = p_n(x_n)$, so $x_{n+1} \in x_n U_n$, and $x_{n+1}U_{n+1} \subseteq x_{n+1}U_n = x_nU_n$. A decreasing sequence of nonempty closed subsets of the compact space G has nonempty intersection, and any $h \in \bigcap C_n$ satisfies $p_n(h) = p_n(x_n) = h_n$ for all n. A continuous bijection from a compact space to a Hausdorff space is a homeomorphism, so $H \simeq \varprojlim H_n$. For a closed normal N, the same argument applied to the finite groups G/NU_n shows $G/N \simeq \varprojlim G/NU_n$; injectivity now needs $\bigcap_n NU_n = N$, which holds because N is closed: if $g \notin N$, the closed sets $N \cap gU_n$ are decreasing with empty intersection (as $\bigcap_n gU_n = \{g\}$), so one of them is empty by compactness, that is, $g \notin NU_n$ for some n. The image of a compact space under a continuous map is compact, and compact subsets of Hausdorff spaces are closed. (v) We do not prove this; see [143, Chapter I, Section 1] and [142, Chapter IV, Section 2]. (vi) In the proof of (iv) the groups $H_n \le G_n$ and G/NU_n (a quotient of $G/U_n \simeq p_n(G)$) are p-groups when the G_n are. If $f\colon G \to F$ is continuous with $p \nmid \#F$, then by (iii) $f(G)$ is a quotient of G/U_n, a p-group, and has order dividing $\#F$; so it is trivial. □

Proposition 1.78 ($\mathrm{GL}_2(\mathbb{Z}_\ell)$ and its congruence subgroup)**.** *Let ℓ be a prime and $\mathrm{GL}_2(\mathbb{Z}_\ell)$ the group of 2×2 matrices over $\mathbb{Z}_\ell$ with determinant in $\mathbb{Z}_\ell^\times$.*

(i) $\mathrm{GL}_2(\mathbb{Z}_\ell) = \varprojlim \mathrm{GL}_2(\mathbb{Z}/\ell^n)$. *Each reduction map $\mathrm{GL}_2(\mathbb{Z}/\ell^{n+1}) \to \mathrm{GL}_2(\mathbb{Z}/\ell^n)$ ($n \ge 1$) is surjective with kernel $\{I + \ell^n X\} \simeq (M_2(\mathbb{F}_\ell), +)$ of order ℓ^4; so $\#\,\mathrm{GL}_2(\mathbb{Z}/\ell^n) = \ell^{4(n-1)}(\ell^2 - 1)(\ell^2 - \ell)$. For $\ell = 3$, $n = 2$: $\#\,\mathrm{GL}_2(\mathbb{Z}/9) = 81 \cdot 48 = 3888$.*

(ii) The kernel $\Gamma(\ell) = I + \ell M_2(\mathbb{Z}_\ell)$ of reduction modulo ℓ is a pro-ℓ group.

(iii) If ℓ is odd, $\Gamma(\ell)$ is torsion-free. Hence every finite subgroup of $\mathrm{GL}_2(\mathbb{Z}_\ell)$ maps isomorphically onto its image in $\mathrm{GL}_2(\mathbb{F}_\ell)$. For $\ell = 2$ this fails: $-I \in \Gamma(2)$.

Proof. (i) $M_2(\mathbb{Z}_\ell) = \varprojlim M_2(\mathbb{Z}/\ell^n)$ entrywise, and a matrix is invertible over $\mathbb{Z}_\ell$ iff its determinant is a unit, iff the determinant is nonzero modulo ℓ (Example 1.76(a)), iff all its reductions are invertible. Given $\bar g \in \mathrm{GL}_2(\mathbb{Z}/\ell^n)$, any lift g to $M_2(\mathbb{Z}/\ell^{n+1})$ has $\det g \equiv \det \bar g \not\equiv 0 \pmod{\ell}$, so it is invertible: the reduction is surjective. Its kernel consists of the $I + \ell^n X$, with X well defined modulo ℓ, and $(I + \ell^n X)(I + \ell^n Y) = I + \ell^n(X + Y) + \ell^{2n}XY \equiv I + \ell^n(X + Y) \pmod{\ell^{n+1}}$, as $2n \ge n + 1$; these matrices are invertible (determinant $\equiv 1 \bmod \ell$). So the kernel is isomorphic to $(M_2(\mathbb{F}_\ell), +)$, and the order follows by induction from Proposition 1.43. (ii) $\Gamma(\ell)$ is the kernel of the continuous map p_1, hence closed, and by the proof of Proposition 1.77(iv) it is the inverse limit of its images in $\mathrm{GL}_2(\mathbb{Z}/\ell^n)$, which lie in the kernels of $\mathrm{GL}_2(\mathbb{Z}/\ell^n) \to \mathrm{GL}_2(\mathbb{F}_\ell)$, groups of order $\ell^{4(n-1)}$. (iii) Let $g \in \Gamma(\ell)$, $g \ne I$, and write $g = I + \ell^k A$ with $k \ge 1$ and $A \in M_2(\mathbb{Z}_\ell)$, $A \not\equiv 0 \pmod{\ell}$. Then

$$g^\ell = I + \ell^{k+1}A + \sum_{i=2}^{\ell-1} \binom{\ell}{i} \ell^{ki} A^i + \ell^{k\ell} A^\ell.$$

(the binomial expansion is valid because I commutes with A). For $2 \le i \le \ell - 1$ the prime ℓ divides $\binom{\ell}{i}$ and $ki \ge 2k$, so the term is divisible by ℓ^{1+2k}, and $1 + 2k \ge k + 2$ as $k \ge 1$. The last term is divisible by $\ell^{k\ell}$, and $k\ell \ge k + 2$ because $k(\ell - 1) \ge 2$ for $\ell \ge 3$. So all terms after $\ell^{k+1}A$ are divisible by ℓ^{k+2}, and $g^\ell = I + \ell^{k+1}A_1$ with $A_1 \equiv A \pmod{\ell}$. (For $\ell = 2$ and $k = 1$ the last term $\ell^{2k}A^2 = 4A^2$ is divisible by ℓ^{k+1} but not in general by ℓ^{k+2}, and the argument breaks down, as it must since $-I = I + 2(-I)$ has order 2.) Since $A_1 \not\equiv 0 \pmod{\ell}$, the same step applies to g^ℓ with $k+1$ in place of k; by induction $g^{\ell^s} = I + \ell^{k+s}A_s$ with $A_s \equiv A \not\equiv 0 \pmod{\ell}$. Now let $m \ge 1$, $m = \ell^s m'$ with $\ell \nmid m'$, and $h = g^{\ell^s}$. Then $h^{m'} = I + m'\ell^{k+s}A_s + \sum_{i \ge 2} \binom{m'}{i} \ell^{(k+s)i} A_s^i$, and every

term of the sum is divisible by $\ell^{2(k+s)}$, hence by ℓ^{k+s+1}; so $h^{m'} \equiv I + m'\ell^{k+s}A_s \pmod{\ell^{k+s+1}}$. As $m'A_s \not\equiv 0 \pmod{\ell}$, this is not I modulo ℓ^{k+s+1}, and $g^m = h^{m'} \neq I$. Thus g has infinite order. If $H \leq \mathrm{GL}_2(\mathbb{Z}_\ell)$ is finite, $H \cap \Gamma(\ell)$ is a finite subgroup of a torsion-free group, hence trivial, and reduction is injective on H. Finally $-I = I + 2(-I)$ has order 2. □

In the paper 1.79. The proof of Lemma lem:IV uses Proposition 1.78(iii) with $\ell = 3$: "reduction modulo 3 is injective on it, the kernel of $\mathrm{GL}_2(\mathbb{Z}_3) \to \mathrm{GL}_2(\mathbb{F}_3)$ being torsion-free", applied to the finite group $\rho_{E,3}(I_q)$; together with Proposition 1.48(iii),(v) this shows that $\rho_{E,3}(I_q)$ is cyclic of order 3. Note the compatibility: an element of order 3 of $\mathrm{GL}_2(\mathbb{Z}_3)$ has eigenvalues the primitive cube roots of unity, characteristic polynomial $X^2 + X + 1$, and reduces to an element of characteristic polynomial $X^2 + X + 1 = (X-1)^2$ in $\mathbb{F}_3[X]$, a nontrivial unipotent; the structure of T_3E as a module over $\mathbb{Z}_3[\zeta_3]$ is Chapter 4 and Chapter 11. Lemma lem:h0 and Lemma lem:tamagawa-exp consider ρ mod ℓ^k, the composite of ρ with $\mathrm{GL}_2(\mathbb{Z}_\ell) \to \mathrm{GL}_2(\mathbb{Z}/\ell^k)$; it is a continuous homomorphism to a finite group, so it factors through a finite quotient of $G_{\mathbb{Q}}$ (Proposition 1.77(iii)).

Example 1.80 (Profinite Galois groups; forward pointers)**.** The following statements are proved in Chapter 5 and Chapter 7; we record them to show where the definitions are used.

(a) $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) = \varprojlim \mathrm{Gal}(K/\mathbb{Q})$ over the finite Galois extensions $K/\mathbb{Q}$, a profinite group (Remark 1.74).

(b) $\mathrm{Gal}(\mathbb{Q}(\mu_{\ell^\infty})/\mathbb{Q}) \simeq \mathbb{Z}_\ell^\times$ through the cyclotomic character χ_ℓ.

(c) $\mathrm{Gal}(\overline{\mathbb{F}}_q/\mathbb{F}_q) \simeq \widehat{\mathbb{Z}}$, topologically generated by the Frobenius $x \mapsto x^q$. A profinite group topologically generated by one element (procyclic) is a quotient of $\widehat{\mathbb{Z}}$.

(d) For a prime p, the inertia group $I_p \leq G_{\mathbb{Q}_p}$ has a normal pro-p subgroup, the wild inertia group, with quotient the tame inertia group $\prod_{\ell \neq p} \mathbb{Z}_\ell(1)$, which is procyclic. So a finite image of inertia of order prime to p is a quotient of the tame inertia group, hence cyclic (by Proposition 1.77(vi) the wild inertia group maps trivially). This is the step "For $q \geq 5$ the image is tame, hence cyclic" in the proof of Proposition prop:shapes, and the step "The order 3 is prime to q, so the image is a quotient of the tame inertia group" in the proof of Lemma lem:IV.

1.8 Exercises

The exercises are graded from routine to harder. Exercises 1.85 to 1.89 check the group-theoretic claims of Proposition prop:ns directly.

Exercise 1.81. Show that $\#\,\mathrm{GL}_2(\mathbb{Z}/9) = 3888$ and $\#\,\mathrm{SL}_2(\mathbb{Z}/9) = 648$. (Use Proposition 1.78(i) and the surjectivity of det onto $(\mathbb{Z}/9)^\times$, a group of order 6.)

Exercise 1.82. Compute the conjugacy classes of D_4 and of Q_8: both have five classes, of sizes $1, 1, 2, 2, 2$. Deduce from the formula $\#G = \sum_\chi \chi(1)^2$ for the degrees of the irreducible complex characters (Riley-Hobson-Bence, the chapter on representation theory; Chapter 4) that both groups have four characters of degree 1 and one of degree 2, although they are not isomorphic. (Hint: in both groups the centre has order 2 and every non-central element g has centraliser of order 4, the subgroup generated by g and the centre; the number of degree-one characters is $\#(G/[G,G]) = 4$, and $8 = 4 \cdot 1^2 + 1 \cdot 2^2$.)

Exercise 1.83. Prove that $C_8 \times C_2$, D_8, SD_{16}, Q_{16} and M_{16} (Remark 1.24) are pairwise non-isomorphic, by counting elements of each order and checking which are abelian. (Caution: counting alone does not separate $C_8 \times C_2$ from M_{16}. In $C_8 \times C_2$ the element (a, b) has order the least common multiple of the orders of a and b, which gives $1, 3, 4, 8$ elements of orders $1, 2, 4, 8$, the same as for M_{16}; these two are distinguished because M_{16} is non-abelian. The other pairs are separated by the table of Remark 1.24.)

Exercise 1.84. Find all subgroups of SD_{16} and identify each up to isomorphism. (There are 15: the trivial group, five of order 2, five of order 4 (three cyclic, two Klein), three of order 8, and SD_{16}.) Which are normal? (Answer: seven: the trivial group, the centre $\langle a^4 \rangle$, the cyclic group $\langle a^2 \rangle$ of order 4, the three subgroups of index 2, and SD_{16}. The other eight have order 2 or 4 and contain some $a^m x$. Such a subgroup K meets $\langle a \rangle$ in a subgroup of $\{1, a^4\}$, so it meets the coset $\langle a \rangle x$ in at most $a^m x$ and $a^{m+4} x$; conjugation by a sends $a^m x$ to $a^{m-2} x$, which is neither, so K is not normal.)

Exercise 1.85. Verify the class table of Proposition 1.59 by listing the 48 elements of $\mathrm{GL}_2(\mathbb{F}_3)$. Then use the orbit-counting lemma (Lemma 1.30) and the column "lines fixed" to show that $N_s(\mathbb{F}_3)$ has two orbits on $\mathbb{P}^1(\mathbb{F}_3)$ and that $N_{ns}(\mathbb{F}_3)$ has one.

Exercise 1.86. Check the paper's claims that the determinant-one subgroup of $N_s(\mathbb{F}_3)$ is cyclic of order 4, generated by $\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, and that the determinant-one subgroup of $N_{ns}(\mathbb{F}_3)$ is the quaternion group.

Exercise 1.87. Check the paper's claim that $N_s(\mathbb{F}_3)$ has two orbits of size two on the four lines of $\mathbb{F}_3^2$ (the two lines of the Cartan subgroup and the two others), while $N_{ns}(\mathbb{F}_3)$ and $\mathrm{GL}_2(\mathbb{F}_3)$ are transitive. Find an element of $N_{ns}(\mathbb{F}_3)$ that maps ∞ to 1. (One answer: $a = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right) \in C_{ns}(\mathbb{F}_3)$ sends e_1 to $\binom{1}{1}$, that is $\infty \mapsto 1$; its powers move ∞ through all four lines.)

Exercise 1.88. Show that $C_{ns}(\mathbb{F}_3)$ contains no element of determinant -1 and trace 0, and conclude that the image of $\bar{\rho}_{E,3}$ for an elliptic curve over $\mathbb{Q}$ is never conjugate to $C_{ns}(\mathbb{F}_3)$ (the label 3Cn), using that complex conjugation maps to an element of determinant -1 and order 2.

Exercise 1.89. Show that every subgroup of $\mathrm{GL}_2(\mathbb{F}_3)$ of order 6 stabilises a line. Classify these subgroups up to conjugacy: two classes isomorphic to S_3 (3B.1.1 and 3B.1.2) and one cyclic class, $\{\pm I\} \times \mathrm{U}$. Show that 3B.1.1 and 3B.1.2 are interchanged by $g \mapsto (g^{-1})^{\mathsf{T}}$, which is an automorphism of $\mathrm{GL}_2(\mathbb{F}_3)$ but not an inner one. (Hint: a subgroup of order 6 contains an element of order 3, so its Sylow 3-subgroup U_L is normal in it, and the argument in the proof of Proposition 1.61 shows that it stabilises L. The map $g \mapsto (g^{-1})^{\mathsf{T}}$ is a homomorphism because both inversion and transposition reverse products. It is not inner: an inner automorphism maps a subgroup with a nonzero fixed vector to a conjugate subgroup, which again has one, whereas 3B.1.2 has none.)

Exercise 1.90. Prove Theorem 1.52(ii) by direct computation: for each of the eight class representatives of Proposition 1.59, compare the determinant with the sign of the induced permutation of the four lines.

Exercise 1.91. Let q be odd. Show that $N_{ns}(\mathbb{F}_q) \cap \mathrm{SL}_2(\mathbb{F}_q)$ has a unique element of order 2, namely $-I$, and that its elements outside $C_{ns}(\mathbb{F}_q)$ have order 4. (Use $(m_c \sigma)^2 = N(c) I$.) For $q = 3$ this recovers Q_8; what is the group for $q = 5$? (Answer: a group of order $2(q+1) = 12$ containing the cyclic group $C_{ns}(\mathbb{F}_5) \cap \mathrm{SL}_2(\mathbb{F}_5) \simeq C_6$ with index 2, whose six other elements have order 4

and square to $-I$. It has $1, 1, 2, 6, 2$ elements of orders $1, 2, 3, 4, 6$ (checked by enumeration); it is the dicyclic group $C_3 \rtimes C_4$, in which a generator of C_4 inverts C_3: among the five groups of order 12 (C_{12}, $C_6 \times C_2$, A_4, D_6 and this one; we do not prove the classification here) it is the only one with a unique involution and no element of order 12.)

Exercise 1.92. (Harder.) Show that $N_s(\mathbb{F}_5)$ is a Sylow 2-subgroup of $\mathrm{GL}_2(\mathbb{F}_5)$, and that its image in $\mathrm{PGL}_2(\mathbb{F}_5) \simeq S_5$, a dihedral group of order 8, lies in a subgroup isomorphic to S_4. (Show that $N_s(\mathbb{F}_5)$ and $\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$ generate a subgroup of order 96 containing the scalars.)

Exercise 1.93. Show that $I + 3M_2(\mathbb{Z}_3)$ is torsion-free, and that $I + 2M_2(\mathbb{Z}_2)$ contains elements of order 2 (for instance $-I$ and $\mathrm{diag}(1, -1)$) but no element of order 4. (Hint: an element g of order 4 of $\mathrm{GL}_2(\mathbb{Z}_2)$ has eigenvalues $\pm\sqrt{-1}$, so its characteristic polynomial is $X^2 + 1$ and $g^2 = -I$; if $g = I + 2A$ and $g^2 = -I$, then $4(A + A^2) = -2I$.)

Exercise 1.94. Let $p \neq \ell$ be primes. Show that the image of a continuous homomorphism $\mathbb{Z}_p \to \mathrm{GL}_2(\mathbb{F}_\ell)$ is cyclic of p-power order, and deduce that it is trivial when $p \nmid \#\,\mathrm{GL}_2(\mathbb{F}_\ell)$. (This is a first instance of the tame inertia arguments of Chapter 7.) (Hint: the kernel is open, so contains some $p^n\mathbb{Z}_p$ by Example 1.76(d), and the image is a quotient of $\mathbb{Z}_p/p^n\mathbb{Z}_p \simeq \mathbb{Z}/p^n$; apply Proposition 1.77(vi) for the last part, $\mathbb{Z}_p$ being pro-p.)

1.9 Notes and references

The elementary group theory of Section 1.1 to Section 1.4 follows [58] (Chapters 1 to 6; in particular Section 3.2 for Lagrange, Section 3.3 for the isomorphism theorems, Sections 4.1 to 4.3 for actions and the class equation, Section 4.5 for the Sylow theorems, Section 5.2 for finite abelian groups and Section 5.5 for semidirect products). Dummit and Foote write D_{2n} for our D_n. The proof of Cauchy's theorem is McKay's, and the existence proof in Theorem 1.33 is Wielandt's; both are standard. The proof of the structure theorem in Theorem 1.35 is the elementary one; the general theorem for finitely generated modules over a principal ideal domain is proved in Chapter 3.

The matrix groups of Section 1.5 are treated in [109, Chapter XIII] (the simplicity of PSL_2 is in Section 8 there) and, for the subgroup structure relevant to Galois representations, in [171, Section 2], where Propositions 15 and 16 give the classification we quote as Theorem 1.57; Dickson's original treatment is [54], and [85, Chapter II, Section 8] is a thorough modern account of the groups $\mathrm{PSL}_2(\mathbb{F}_q)$. The uniqueness of the simple group of order 168 is in [58, Section 6.2].

The tables of Section 1.6 were computed by hand and checked by a complete enumeration of the elements and subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$; the orders for $q = 5, 7$ and the subgroup of order 96 of $\mathrm{GL}_2(\mathbb{F}_5)$ were checked in the same way. Sutherland's labels are defined in [191], and the list of mod ℓ images of elliptic curves over $\mathbb{Q}$ is [210]; both are discussed in Chapter 11. The paper cites [210] for the list of three images in Proposition prop:ns and derives it from three properties by inspection; Theorem 1.65 carries out that inspection.

For profinite groups we follow [142, Chapter IV, Sections 1 and 2] and [143, Chapter I, Section 1]; Tychonoff's theorem is [139, Theorem 37.3]. The torsion-freeness of the congruence subgroup $\Gamma(\ell)$ for odd ℓ is elementary; for its role in the study of ℓ-adic images see [171, Section 4].

Chapter 2

Rings, fields, polynomials and characters

The paper is written for readers who handle rings, finite fields and quadratic characters without thinking about them. This chapter makes that background explicit, with complete proofs, and organises it around the seven places where the paper actually uses it: the ℓ-adic valuations of rational numbers in Definition def:terms and the table of Section 1; the quadratic characters χ_{-3}, χ_{-4}, χ_{q^*} and χ_S as Dirichlet characters; quadratic reciprocity, which makes χ_{q^*} the quadratic character of conductor q; the ℓ-th powers in $\mathbb{F}_q^\times$ and the class c of Lemma lem:tamfactor; the ring theory behind Lemma lem:crit ($\mathbb{T}/(I+J)$ is cyclic, and its order is divisible by the residue characteristic of every maximal ideal containing $I+J$); the congruence $a^2 \equiv 1 \pmod{\ell^k}$ behind Lemma lem:h0; and the foundations (ideals, unique factorisation, Gauss's lemma, Eisenstein's criterion, finite fields, cyclotomic polynomials, Gauss sums) that Chapters 3, 5, 6 and 7 build on. The group theory it needs (cyclic groups, finite abelian groups, finite subgroups of $K^\times$) is in Chapter 1 and is used, not reproved.

Core results at a glance

Rings are commutative with 1. The letters p, q, ℓ denote primes, except in Sections 2.6 and 2.7, where $q = p^r$ is the size of a finite field; in the paper q is a prime, so $\mathbb{F}_q = \mathbb{Z}/q\mathbb{Z}$ there. Quadratic characters are named by their discriminant: $\chi_D = \left(\frac{D}{\cdot}\right)$ for a fundamental discriminant D (for other discriminants the Kronecker symbol $\left(\frac{D}{\cdot}\right)$ is written out), so χ_{q^*} (never χ_q) is the character of conductor q, and χ_ℓ is the ℓ-adic cyclotomic character.

2.1 Conventions. Rings, homomorphisms and subrings are unital; p, q, ℓ are primes (q a prime power in Sections 6 and 7); $v_p(0) = +\infty$, $|x|_p = p^{-v_p(x)}$, and for $c \in \mathbb{Z}/\ell^m$, $v_\ell(c) = \min(v_\ell(\tilde{c}), m)$; the Kronecker symbol at 2 and at -1; Dirichlet characters and the names χ_D (D fundamental), χ_{q^*}, ω_ℓ, χ_0, $\chi^{(p)}$; $\zeta_n = e^{2\pi i/n}$ and $\sqrt{-3} = 1 + 2\zeta_3$. Conventions 2.1 to 2.6.

2.2 Rings (definition: ring, unit group $R^\times$, zero divisor, nilpotent, field, integral domain, subring, homomorphism, kernel, image). Definition 2.7.

2.3 Characteristic. For every ring R there is a unique homomorphism $\mathbb{Z} \to R$; its kernel is $n\mathbb{Z}$ for a unique $n \geq 0$, the characteristic. A domain has characteristic 0 or a prime, and a

finite domain is a field. *(proved here)* Proposition 2.9.

2.4 Ideals (definition: ideal, the ideal generated by a set, $I+J$, IJ, $I\cap J$, the annihilator $\mathrm{Ann}_R(S)$, comaximal ideals, the quotient ring R/I). Definition 2.10.

2.5 Ideals and kernels. Kernels of homomorphisms are exactly the ideals; $IJ\subseteq I\cap J$; every ideal of $\mathbb{Z}$ is $n\mathbb{Z}$ for a unique $n\geq 0$; $m\mathbb{Z}+n\mathbb{Z}=\gcd(m,n)\mathbb{Z}$ and $m\mathbb{Z}\cap n\mathbb{Z}=\mathrm{lcm}(m,n)\mathbb{Z}$. *(proved here)* Proposition 2.11.

2.6 Isomorphism theorems. (i) $R/\ker\phi\simeq\phi(R)$. (ii) Ideals of R/I correspond to ideals $J\supseteq I$ of R, with $(R/I)/(J/I)\simeq R/J$. (iii) If $\phi\colon R\to S$ is surjective with kernel I and J is an ideal of R, then $\phi(J)$ is an ideal and $R/(I+J)\simeq S/\phi(J)$. (iv) Every quotient ring of $\mathbb{Z}$ is $\mathbb{Z}/r\mathbb{Z}$, cyclic as a group. *(proved here)* Theorem 2.12.

2.7 Two ideals. The sequence $0\to R/(I\cap J)\to R/I\times R/J\to R/(I+J)\to 0$, $x\mapsto(x,x)$, $(y,z)\mapsto y-z$, is exact. If $I+J=R$ then $I\cap J=IJ$ and $R/IJ\simeq R/I\times R/J$; if $I_1,\dots,I_k$ are pairwise comaximal, $R/I_1\cdots I_k\simeq\prod R/I_i$. *(proved here)* Proposition 2.13.

2.8 Idempotents. If $e^2=e$ then $R\simeq Re\times R(1-e)$; R is a product of two nonzero rings iff it has an idempotent $e\neq 0,1$. The ideals of $R_1\times R_2$ are the $I_1\times I_2$, its prime ideals the $P_1\times R_2$ and $R_1\times P_2$. *(proved here)* Proposition 2.14.

2.9 Frobenius in characteristic p. $(x+y)^{p^k}=x^{p^k}+y^{p^k}$, so $x\mapsto x^p$ is a ring endomorphism; it is injective on a domain and bijective on a finite field; $a^p\equiv a\pmod p$. *(proved here)* Proposition 2.16.

2.10 Prime and maximal ideals. R/P is a domain iff P is prime, R/M a field iff M is maximal; maximal ideals are prime; preimages of primes are prime; the kernel of a map onto a field (or to a field with finite image) is maximal; if R/P is finite, P is prime iff maximal; the primes of $\mathbb{Z}$ are 0 and $p\mathbb{Z}$; every non-unit lies in a maximal ideal (Zorn). *(proved here)* Theorem 2.17.

2.11 Residue characteristic. If $\mathfrak{m}$ is maximal with $R/\mathfrak{m}$ of characteristic $\ell>0$ and $\mathfrak{a}\subseteq\mathfrak{m}$ is an ideal with $R/\mathfrak{a}$ finite, then $\ell\mid\#R/\mathfrak{a}$; a homomorphism $\mathbb{Z}/r\to k$ to a field of characteristic ℓ exists iff $\ell\mid r$. *(proved here)* Proposition 2.18.

2.12 Field of fractions. A domain R embeds in a field $\mathrm{Frac}(R)$, and every injective homomorphism from R to a field extends uniquely to $\mathrm{Frac}(R)$. *(proved here)* Theorem 2.20.

2.13 The ring $\mathbb{Z}_{(p)}$. $\mathbb{Z}_{(p)}=\{a/b : p\nmid b\}$ has units $\{a/b : p\nmid ab\}$, nonzero ideals $p^k\mathbb{Z}_{(p)}$, a unique maximal ideal $p\mathbb{Z}_{(p)}$, and a surjective reduction map $\mathbb{Z}_{(p)}\to\mathbb{F}_p$ with kernel $p\mathbb{Z}_{(p)}$; $\mathbb{Z}_{(p)}=\{x : v_p(x)\geq 0\}$ and $\mathbb{Z}=\bigcap_p\mathbb{Z}_{(p)}$. *(proved here)* Proposition 2.21.

2.14 Divisibility (definition: associates, irreducible and prime elements, Euclidean domain, PID, UFD, gcd). Definition 2.23.

2.15 Primes and irreducibles. In a domain a prime element is irreducible, and (a) is a nonzero prime ideal iff a is a prime element; a factorisation into prime elements is unique up to order and units. *(proved here)* Lemma 2.24.

2.16 Euclid, PID, UFD. A Euclidean domain is a PID; a PID is Noetherian and a UFD, with Bezout's identity and nonzero primes maximal; in a UFD irreducibles are prime. $\mathbb{Z}$ and $F[x]$ are Euclidean; $\mathbb{Z}[x]$ and $F[x,y]$ are UFDs, not PIDs. *(proved here)* Theorem 2.25.

2.17 Arithmetic of $\mathbb{Z}$. Bezout, Euclid's lemma, $n = \pm\prod p^{v_p(n)}$, gcd and lcm by min and max of exponents. *(proved here)* Proposition 2.26.

2.18 $\mathbb{Z}[i]$ and $\mathbb{Z}[\zeta_3]$. Both are Euclidean for $N(z) = |z|^2$ (remainders of norm at most $\frac{1}{2}N(\beta)$, resp. $\frac{1}{3}N(\beta)$), hence PIDs and UFDs; $\mathbb{Z}[i]^\times = \mu_4$, $\mathbb{Z}[\zeta_3]^\times = \mu_6$; elements of prime norm are prime. *(proved here)* Theorem 2.27.

2.19 Polynomials. Over a domain $\deg fg = \deg f + \deg g$ and $R[x]^\times = R^\times$; division by a monic polynomial over any ring; $F[x]$ is Euclidean, its maximal ideals are the (f), f irreducible; factor theorem; at most d roots in a domain. *(proved here)* Proposition 2.30.

2.20 Repeated roots. a is a multiple root of f iff $f(a) = f'(a) = 0$; f has no repeated root in any extension iff $\gcd(f, f') = 1$; $x^{p^r} - x$ and, when $\operatorname{char} F \nmid n$, $x^n - 1$ are separable. *(proved here)* Proposition 2.31.

2.21 Gauss's lemma. Over a UFD R with fraction field K: contents multiply; a factorisation in $K[x]$ descends to $R[x]$; a primitive polynomial is irreducible in $R[x]$ iff in $K[x]$; $R[x]$ is a UFD; rational root test. *(proved here)* Theorem 2.32.

2.22 Eisenstein's criterion. If $a_n \notin P$, $a_i \in P$ for $i < n$, $a_0 \notin P^2$ (P prime), then f is not a product of two polynomials of positive degree; over a UFD a primitive such f is irreducible in $R[x]$ and $K[x]$. *(proved here)* Theorem 2.33.

2.23 Reduction modulo p. If p does not divide the leading coefficient of a primitive $f \in \mathbb{Z}[x]$ and $\bar{f}$ is irreducible in $\mathbb{F}_p[x]$, then f is irreducible in $\mathbb{Q}[x]$; the degrees of a rational factorisation are sums of degrees of the factors of $\bar{f}$. *(proved here)* Proposition 2.34.

2.24 Kronecker's construction. For $f \in F[x]$ irreducible of degree d, $F[x]/(f)$ is a field of degree d in which $\bar{x}$ is a root of f; $F[x]/(f) \simeq F[\alpha]$ for any root α; every polynomial splits in a finite extension. *(proved here)* Theorem 2.38.

2.25 The ring $\mathbb{Z}/n\mathbb{Z}$. a is a unit iff $\gcd(a,n) = 1$; $\mathbb{Z}/n$ is a field iff n is prime; $\#(\mathbb{Z}/n)^\times = \varphi(n)$, $a^{\varphi(n)} \equiv 1$, $\varphi(p^k) = p^{k-1}(p-1)$, $\sum_{d\mid n}\varphi(d) = n$; $(\mathbb{Z}/n)^\times = \operatorname{Aut}(\mathbb{Z}/n)$. *(proved here)* Proposition 2.40.

2.26 Chinese remainder theorem. $\mathbb{Z}/mn \simeq \mathbb{Z}/m \times \mathbb{Z}/n$ iff $\gcd(m,n) = 1$; $\mathbb{Z}/n \simeq \prod \mathbb{Z}/p_i^{k_i}$, $(\mathbb{Z}/n)^\times \simeq \prod(\mathbb{Z}/p_i^{k_i})^\times$, φ is multiplicative. *(proved here)* Theorem 2.41.

2.27 Lifting the exponent. For odd ℓ, $\ell \mid a-b$, $\ell \nmid ab$: $v_\ell(a^n - b^n) = v_\ell(a-b) + v_\ell(n)$; for odd a and even n, $v_2(a^n-1) = v_2(a-1) + v_2(a+1) + v_2(n) - 1$; $1+\ell$ has order ℓ^{k-1} modulo ℓ^k; $v_\ell(q^f - 1)$ for $q \neq \ell$; $v_\ell(q^2-1) = v_\ell(q-1) + v_\ell(q+1)$. *(proved here)* Lemma 2.42.

2.28 Primitive roots. $(\mathbb{Z}/p^k)^\times$ is cyclic for odd p; $(\mathbb{Z}/2^k)^\times = \{\pm 1\} \times \langle 5\rangle$ for $k \geq 3$; $(\mathbb{Z}/n)^\times$ is cyclic iff $n \in \{1, 2, 4, p^k, 2p^k\}$, p odd. *(proved here)* Theorem 2.43.

2.29 Squares congruent to one. For odd ℓ and $k \geq 1$, $a^2 \equiv 1 \pmod{\ell^k}$ iff $a \equiv \pm 1$; every unit squares to 1 modulo ℓ^k iff $\ell^k = 3$; a homomorphism onto $(\mathbb{Z}/\ell^k)^\times$ (or one whose image contains 2) with $\chi^2 \equiv 1$ forces $\ell^k = 3$. *(proved here)* Corollary 2.44.

2.30 Finite fields. A finite field has prime characteristic p and p^r elements; $F^\times$ is cyclic; $x^{p^r} - x = \prod_{a\in F}(x-a)$; $F = \mathbb{F}_p[\alpha]$ for a generator α of $F^\times$. *(proved here)* Proposition 2.46.

2.31 Existence and uniqueness. For every prime power $q = p^r$ there is a field with q elements, unique up to isomorphism, isomorphic to $\mathbb{F}_p[x]/(f)$ for every irreducible f of degree r. *(proved here)* Theorem 2.47.

2.32 Frobenius and subfields. $\mathrm{Frob}_p\colon x \mapsto x^p$ is an automorphism of $\mathbb{F}_{p^r}$ of order r with fixed field $\mathbb{F}_p$; $\mathbb{F}_{p^r}$ has a subfield with p^d elements iff $d \mid r$, and then exactly one; the fixed field of Frob_p^s is $\mathbb{F}_{p^{\gcd(s,r)}}$. *(proved here)* Proposition 2.48.

2.33 Irreducible polynomials over $\mathbb{F}_q$. $x^{q^r} - x$ is the product of the monic irreducibles of degree dividing r; $q^r = \sum_{d|r} dN_d$ and $N_r = \frac{1}{r}\sum_{d|r}\mu(d)q^{r/d} > 0$. *(proved here)* Proposition 2.49.

2.34 Roots of unity in $\mathbb{F}_q$. $\mu_n(\mathbb{F}_q)$ is cyclic of order $\gcd(n, q-1)$; the least f with $\mu_n \subset \mathbb{F}_{q^f}$ is the order of q modulo n; no nontrivial p-power roots of unity; -1 is a square iff $q \equiv 1 \pmod 4$, -3 (for $p \neq 2, 3$) iff $q \equiv 1 \pmod 3$; for σ of order 3 (resp. 4) and m prime to 3 (resp. odd), $\sigma^m = \sigma^{\pm 1}$ according to m modulo 3 (resp. 4). *(proved here)* Proposition 2.50.

2.35 Powers in $\mathbb{F}_q^\times$. For $d = \gcd(m, q-1)$, $(\mathbb{F}_q^\times)^m = (\mathbb{F}_q^\times)^d$ has index d; u is an m-th power iff $u^{(q-1)/d} = 1$; $[\mathbb{F}_q^\times : (\mathbb{F}_q^\times)^{\ell^k}] = \ell^{\min(k, v_\ell(q-1))}$. *(proved here)* Theorem 2.52.

2.36 The class $c(u)$. For $\ell \nmid q$ and $v = v_\ell(q-1)$, $\mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^v}$ is cyclic of order ℓ^v; a generator identifies it with $\mathbb{Z}/\ell^v$, and $v_\ell(c(u))$ does not depend on the generator; for $k \le v$, u is an ℓ^k-th power iff $v_\ell(c(u)) \ge k$; $\min(v_\ell(n), v, v_\ell(c(u))) \ge 1$ iff $\ell \mid n$, $q \equiv 1 \pmod \ell$ and $u \in (\mathbb{F}_q^\times)^\ell$. *(proved here)* Proposition 2.53.

2.37 Roots of unity (definition: $\mu_n(K)$, $\mu(K)$, primitive n-th root of unity). Definition 2.56.

2.38 Roots of unity in fields. $\mu_n(K)$ is cyclic of order dividing n, and of order n only if $\mathrm{char}\, K \nmid n$; $\mu_n(\mathbb{C}) = \langle\zeta_n\rangle$; $\mu(\mathbb{Q}) = \{\pm 1\}$, $\mu(\mathbb{Q}(i)) = \mu_4$, $\mu(\mathbb{Q}(\zeta_3)) = \mu_6$. *(proved here)* Proposition 2.57.

2.39 Cyclotomic polynomials. $x^n - 1 = \prod_{d|n}\Phi_d$; $\Phi_n \in \mathbb{Z}[x]$ is monic of degree $\varphi(n)$; $\Phi_n = \prod_{d|n}(x^d-1)^{\mu(n/d)}$; formulas for Φ_{p^k}, Φ_{2m}, $\Phi_n(1)$, $\Phi_n(0)$; Φ_{p^k} is irreducible over $\mathbb{Q}$. *(proved here)* Theorem 2.58.

2.40 Cyclotomic polynomials modulo p. For $p \nmid n$ the roots of Φ_n in characteristic p are the elements of order n; $p \mid \Phi_n(a)$ iff a has order n modulo p, so $p \equiv 1 \pmod n$; there are infinitely many primes $\equiv 1 \pmod n$; Φ_n splits modulo p iff $p \equiv 1 \pmod n$. *(proved here)* Proposition 2.59.

2.41 Legendre symbol (definition). Definition 2.60.

2.42 Euler's criterion. $\left(\frac{a}{p}\right) \equiv a^{(p-1)/2} \pmod p$; the symbol is the unique character of order 2 of $(\mathbb{Z}/p)^\times$; $\left(\frac{-1}{p}\right) = (-1)^{(p-1)/2}$; $\left(\frac{a}{3}\right) \equiv a \pmod 3$. *(proved here)* Proposition 2.61.

2.43 The quadratic Gauss sum. In a field of characteristic $\neq q$ with a primitive q-th root of unity ζ, $g = \sum\left(\frac{a}{q}\right)\zeta^a$ satisfies $g^2 = q^* = (-1)^{(q-1)/2}q$ and $\sum\left(\frac{a}{q}\right)\zeta^{ab} = \left(\frac{b}{q}\right)g$; so $\sqrt{q^*} \in \mathbb{Q}(\zeta_q)$. *(proved here; the sign of g over $\mathbb{C}$ is stated in Remark 2.63)* Proposition 2.62.

2.44 Quadratic reciprocity. For odd primes $p \neq q$: $\left(\frac{p}{q}\right)\left(\frac{q}{p}\right) = (-1)^{\frac{p-1}{2}\frac{q-1}{2}}$, i.e. $\left(\frac{q^*}{p}\right) = \left(\frac{p}{q}\right)$; $\left(\frac{-1}{p}\right) = (-1)^{(p-1)/2}$; $\left(\frac{2}{p}\right) = (-1)^{(p^2-1)/8}$. *(proved here)* Theorem 2.64.

2.45 Jacobi symbol (definition). Definition 2.65.

2.46 Jacobi reciprocity. The Jacobi symbol is multiplicative in both entries, periodic in the top one, and satisfies reciprocity and both supplements; $\left(\frac{a}{n}\right) = 1$ does not make a a square modulo n. *(proved here)* Proposition 2.66.

2.47 Kronecker symbol, discriminants (definition: the Kronecker symbol $\left(\frac{a}{n}\right)$ for all $a, n \in \mathbb{Z}$; discriminant; fundamental and prime discriminants; $\chi_D = \left(\frac{D}{\cdot}\right)$ for fundamental D). Definition 2.67.

2.48 Kronecker characters. For a discriminant D, $n \mapsto \left(\frac{D}{n}\right)$ is completely multiplicative, vanishes iff $\gcd(D, n) > 1$, and is a real Dirichlet character modulo $|D|$ with value $\operatorname{sgn} D$ at -1; values at primes; $\left(\frac{DD'}{\cdot}\right) = \left(\frac{D}{\cdot}\right)\left(\frac{D'}{\cdot}\right)$ for discriminants D, D', and $\left(\frac{Df^2}{n}\right) = \left(\frac{D}{n}\right)$ for $\gcd(n, f) = 1$. *(proved here)* Proposition 2.68.

2.49 The character χ_{q^*}. $q^* \equiv 1 \pmod 4$, and $\left(\frac{q^*}{n}\right) = \left(\frac{n}{q}\right)$ for every $n \in \mathbb{Z}$; χ_{q^*} is the unique character of order 2 and conductor q; the same for ℓ^*; $3^* = -3$, $5^* = 5$, $7^* = -7$, $11^* = -11$, $13^* = 13$. *(proved here)* Proposition 2.69.

2.50 Dirichlet characters (definition: character modulo n, principal character, parity, the group $X(n)$, characters with values in another field, ω_ℓ). Definition 2.71.

2.51 Basic properties. Complete multiplicativity, periodicity, values in $\mu_{\varphi(n)}$, $\bar\chi = \chi^{-1}$, $\chi(-1) = \pm 1$; $X(n) \simeq (\mathbb{Z}/n)^\times$ non-canonically. *(proved here)* Proposition 2.72.

2.52 Orthogonality. $\sum_a \chi(a) = \varphi(n)[\chi = \chi_0]$, $\sum_\chi \chi(a) = \varphi(n)[a \equiv 1]$, where the Iverson bracket $[P]$ is 1 if the statement P holds and 0 otherwise; the characters are an orthonormal basis of the functions on $(\mathbb{Z}/n)^\times$. *(proved here)* Theorem 2.73.

2.53 Conductor (definition: χ defined modulo d, conductor f_χ, primitive character). Definition 2.74.

2.54 Conductors. If χ is defined modulo d_1 and d_2, it is defined modulo $\gcd(d_1, d_2)$; the conductor divides every such modulus and χ is induced by a unique primitive χ^{prim}; $f_\chi = \prod_p f_{\chi^{(p)}}$ for the p-components $\chi^{(p)}$; products of primitive characters of coprime conductors are primitive; χ_{-4}, $\chi_{\pm 8}$ have conductor 4, 8, and χ_S has conductor $\prod_{q \in S} q$. *(proved here)* Proposition 2.75.

2.55 Fundamental discriminants. A fundamental discriminant $D \neq 1$ is uniquely a product of coprime prime discriminants $-4, 8, -8, q^*$; χ_D is primitive of conductor $|D|$. *(proved here)* Corollary 2.76.

2.56 Gauss sums. $\tau(\chi, b) = \bar\chi(b)\tau(\chi)$ for b prime to n, and for all b if χ is primitive; then $|\tau(\chi)|^2 = n$ and $\tau(\chi)\tau(\bar\chi) = \chi(-1)n$; $\tau(\chi_{-4}) = 2i$, $\tau(\chi_{-3}) = \sqrt{-3}$; $\tau(\chi) = \mu(n/f)\chi^{\text{prim}}(n/f)\tau(\chi^{\text{prim}})$ when $\gcd(n/f, f) = 1$. *(proved here)* Theorem 2.77.

2.57 The paper's characters. The table of χ_{-4}, χ_{-3}, χ_{q^*}, χ_S, χ_{ℓ^*}, ω_ℓ (Kronecker symbol, conductor, parity, values at primes); $p \equiv \chi_{-3}(p) \pmod 3$ for $p \neq 3$ and $p \equiv \chi_{-4}(p) \pmod 4$ for odd p; $\left(\frac{\cdot}{\ell}\right) = \omega_\ell^{(\ell-1)/2}$, equal to ω_ℓ iff $\ell = 3$; $3 \mid q - \chi_{-4}(q)$ iff $q \equiv \pm 1 \pmod{12}$. *(proved here)* Proposition 2.78.

2.58 Valuations (definition: v_p on $\mathbb{Q}$, $v_p(0) = +\infty$). Definition 2.81.

2.59 Properties of v_p. $v_p(xy) = v_p(x) + v_p(y)$; $v_p(x+y) \geq \min$, with equality if the valuations differ; $v_p \geq 0$ on $\mathbb{Z}_{(p)}$ exactly; $p^k \mid n$ iff $v_p(n) \geq k$; Legendre's formula for $v_p(n!)$. *(proved here)* Proposition 2.82.

2.60 The p-adic absolute value (definition: $|x|_p = p^{-v_p(x)}$). Definition 2.83.

2.61 Absolute values on $\mathbb{Q}$. $|\cdot|_p$ is an ultrametric absolute value; the product formula $\prod_{p \leq \infty} |x|_p = 1$; $\mathbb{Q}$ is not complete for $|\cdot|_p$. *(proved here)* Proposition 2.84.

2.62 Ostrowski's theorem. Every nontrivial absolute value on $\mathbb{Q}$ is equivalent to $|\cdot|_\infty$ or to exactly one $|\cdot|_p$. *(stated; reference)* Theorem 2.85.

2.63 ℓ-integrality. For primes $q \neq \ell$, q is an ℓ-adic unit, $P(q^{-k}) \in \mathbb{Z}_{(\ell)}$ for $P \in \mathbb{Z}[X]$, and $v_\ell(\frac{q-1}{q}) = v_\ell(q-1)$, $v_\ell(1 \mp q^{-1}) = v_\ell(q \mp 1)$ for either sign, $v_\ell(1-q^{-2}) = v_\ell(q-1) + v_\ell(q+1)$. *(proved here)* Lemma 2.86.

2.64 The I_0^* identity. If $\alpha\beta = q$, $\alpha + \beta = a$, then $(1 - \frac{\alpha}{\beta q})(1 - \frac{1}{q})(1 - \frac{\beta}{\alpha q}) = \frac{q-1}{q} \cdot \frac{(q+1)^2 - a^2}{q^2}$, and $(q+1)^2 - a^2 \geq (q-1)^2$ if $a^2 \leq 4q$. *(proved here)* Proposition 2.87.

2.65 The paper's local terms. For primes $q \geq 5$, odd $\ell \neq q$ and $a \in \mathbb{Z}$ with $a^2 \leq 4q$: (i) $v_\ell(q - \chi_{-3}(q)) \geq 1$ always at $\ell = 3$ and iff $q \equiv \chi_{-3}(q) \pmod \ell$ otherwise; (ii) $v_\ell(q - \chi_{-4}(q)) \geq 1$ iff $q \equiv \pm 1 \pmod{12}$ at $\ell = 3$, iff $q \equiv \chi_{-4}(q) \pmod \ell$ otherwise; (iii) $v_\ell(q^2 - 1) \geq 1$ always at $\ell = 3$, iff $q \equiv \pm 1 \pmod \ell$ otherwise; (iv) $v_\ell(q-1) + v_\ell((q+1)^2 - a^2) \geq 1$ iff $q \equiv 1 \pmod \ell$ or $a \equiv \pm(q+1) \pmod \ell$; (v) for $n \geq 1$ and $\bar{u} \in \mathbb{F}_q^\times$, $v_\ell(n) + \min(v_\ell(n), v_\ell(q-1), v_\ell(c(\bar{u}))) > v_\ell(n)$ iff $\ell \mid n$, $q \equiv 1 \pmod \ell$ and $\bar{u} \in (\mathbb{F}_q^\times)^\ell$. *(proved here)* Proposition 2.88.

Where the paper uses this chapter

- **Definition def:terms and the table of Section 1.** The terms $e_\ell(E,q)$ and $t_\ell(E,q)$ are ℓ-adic valuations of integers and of rationals with denominator a power of q: Propositions 2.82, 2.87 and 2.88 and Lemma 2.86 and Example 2.89; the same results give Remark rem:afterquant(1) ($e_3 > 0$ at every prime $q \geq 5$ of type I_n^*). The characters χ_{-3}, χ_{-4} of the table: Proposition 2.78.

- **Lemma lem:euler (the omitted factors at tame primes) and Lemma lem:IV.** "Frobenius centralises σ if $q \equiv 1 \pmod 3$ and inverts it if $q \equiv 2$": Proposition 2.50(v) and Proposition 2.78(ii); the identity for type I_0^*: Proposition 2.87; $e_\ell = v_\ell(1-q^{-2}) = v_\ell(q^2-1)$: Lemma 2.86.

- **Proposition prop:forms.** "$e_3(E,q) = v_3(q - \chi_{-3}(q)) \geq 1 = w_3(E,q)$ since $q \equiv \chi_{-3}(q) \pmod 3$": Proposition 2.78(i), Proposition 2.88(i).

- **Lemma lem:twist, Theorems thm:twist, thm:quant, thm:qual and Example ex:qual.** The character χ_{q^*} of conductor q, the field $\mathbb{Q}(\sqrt{q^*})$, the character χ_S of conductor $D = \prod_{q\in S} q$ and the vanishing of $\chi_S(n)$ for $\gcd(n, D) > 1$: Theorem 2.64 and Propositions 2.69, 2.75 and 2.78.

- **Lemma lem:tamfactor, Remark rem:ko(1) and Section sec:tam.** ℓ-th powers in $\mathbb{F}_q^\times$, the class c of the reduction of the unit part u, and the reading of $v_\ell(c)$: Theorem 2.52 and Proposition 2.53 and Example 2.54; reduction of units: Proposition 2.21(iii).

- **Lemma lem:crit (congruence criterion), Lemma lem:hecke and Step 1 of the proof of Theorem thm:quant.** $\mathbb{T}/(I + J) \simeq \mathbb{Z}/\phi_f(J)$ is cyclic, the cokernel of $\mathbb{T} \subset \mathbb{T}/I \times \mathbb{T}/J$ is $\mathbb{T}/(I+J)$, the decomposition $\mathbb{T}\otimes\mathbb{Q} = \mathbb{Q}\times\mathbb{T}'$, and "$\ell$ divides $\#\mathbb{T}/(I+J) = r$": Theorems 2.12 and 2.17 and Propositions 2.13, 2.14 and 2.18.

- **Lemma lem:fpr.** "$L_p(A_f, 1)^{-1} = L_p(A_f(1), 0)^{-1}$ is a nonzero rational number which is an ℓ-adic integer": Proposition 2.21 and Lemma 2.86.

- **Remark rem:wild.** $P_2(X) = 1 + 2X$ gives $e_3 = v_3(\frac{3}{2}) = 1$; the cubic factors at 2: Example 2.89(e).

- **Section sec:anomaly.** The type III primes with $e_3 > 0$ are those with $q \equiv \pm 1 \pmod{12}$: Proposition 2.78(iv).

- **Lemma lem:h0 and Proposition prop:ns.** $\chi_\ell^2 \equiv 1 \pmod{\ell^k}$ on a group mapping onto $\mathbb{Z}_\ell^\times$ forces $k = 0$ or $\ell^k = 3$: Corollary 2.44; $\bar{\chi}_3^{\mathrm{cyc}} = \chi_{-3}$ on the Dirichlet side: Proposition 2.78(iii); $\mathbb{F}_9 = \mathbb{F}_3[i]$: Theorem 2.38; the 3-division polynomial test: Proposition 2.34 and Example 2.36.

2.1 Rings, ideals, quotients and products

This section fixes the language of rings and ideals and proves the isomorphism theorems, the exact sequence of two ideals and the decomposition of a ring by idempotents. In the paper these are exactly the steps of Lemma lem:crit: the Hecke algebra $\mathbb{T}$ is a ring, $I = \ker\phi_f$ and $J = \mathrm{Ann}_{\mathbb{T}}(f^\perp)$ are ideals with $I \cap J = 0$, the quotient $\mathbb{T}/(I + J)$ is identified with $\mathbb{Z}/\phi_f(J)$, and $\mathbb{T}\otimes\mathbb{Q}$ splits as $\mathbb{Q}\times\mathbb{T}'$. We begin with the conventions of the whole chapter.

Convention 2.1 (rings)**.** Rings are commutative with an identity 1; ring homomorphisms send 1 to 1; subrings contain 1. The zero ring (in which $1 = 0$) is allowed, but fields and integral domains are nonzero by definition. $R^\times$ is the group of units of R. The paper's Hecke algebra $\mathbb{T}$ is such a ring. Matrix rings appear only as examples and are then flagged as non-commutative.

Convention 2.2 (primes and the letter q)**.** The letters p, q, ℓ denote primes unless stated otherwise. In Sections 2.6 and 2.7, and wherever $\mathbb{F}_q$ is written with q not declared prime, $q = p^r$ is a prime power and $\mathbb{F}_q$ is a field with q elements. In the paper q is always a prime (a bad prime of E), so $\mathbb{F}_q = \mathbb{Z}/q\mathbb{Z}$ there and primitive roots modulo q exist. The coefficient prime ℓ is odd in every use of the paper. In one place, Paper link 2.80, q is also the variable $q = e^{2\pi iz}$ of q-expansions (Appendix B, B-C1), and this is said there. No two of these three meanings of q occur in one display.

Convention 2.3 (valuations)**.** For a prime p, $v_p\colon \mathbb{Q} \to \mathbb{Z} \cup \{+\infty\}$ is the p-adic valuation (Definition 2.81), with $v_p(0) = +\infty$ and $v_p(p) = 1$, and $|x|_p = p^{-v_p(x)}$, $|0|_p = 0$. For a nonzero ideal $r\mathbb{Z}$, $v_p(r\mathbb{Z}) := v_p(r)$. For a class $c \in \mathbb{Z}/\ell^m\mathbb{Z}$ put

$$v_\ell(c) := \min\bigl(v_\ell(\tilde{c}), m\bigr) \qquad \text{for any lift } \tilde{c} \in \mathbb{Z} \text{ of } c.$$

This does not depend on the lift: two lifts differ by a multiple of ℓ^m, and $\min(v_\ell(x), m) = \min(v_\ell(x + \ell^m y), m)$ by Proposition 2.82(ii). So $v_\ell(0) = m$, and for $0 \le k \le m$, $v_\ell(c) \ge k$ if and only if $c \in \ell^k\mathbb{Z}/\ell^m\mathbb{Z}$. With this reading the paper's $\min(v_\ell(n), v_\ell(q-1), v_\ell(c))$ in Lemma lem:tamfactor makes sense also when $c = 0$, and also when $v_\ell(q-1) = 0$ (then c lies in the zero group $\mathbb{Z}/1$ and the minimum is 0).

Convention 2.4 (symbols)**.** $\left(\frac{a}{p}\right)$ is the Legendre symbol for an odd prime p (Definition 2.60), $\left(\frac{a}{n}\right)$ the Jacobi symbol for an odd $n > 0$ (Definition 2.65), and $\left(\frac{a}{n}\right)$ the Kronecker symbol for arbitrary $a, n \in \mathbb{Z}$ (Definition 2.67). The three agree where more than one is defined. The Kronecker symbol has $\left(\frac{a}{2}\right) = 0$ for even a, 1 for $a \equiv \pm 1 \pmod 8$ and -1 for $a \equiv \pm 3 \pmod 8$; $\left(\frac{a}{-1}\right) = 1$ for $a \ge 0$ and -1 for $a < 0$; $\left(\frac{a}{1}\right) = 1$; and $\left(\frac{a}{0}\right) = 1$ if $a = \pm 1$, 0 otherwise.

Convention 2.5 (characters and their names)**.** A Dirichlet character modulo n is a function $\chi\colon \mathbb{Z} \to \mathbb{C}$ coming from a homomorphism $(\mathbb{Z}/n)^\times \to \mathbb{C}^\times$, with $\chi(a) = 0$ when $\gcd(a, n) > 1$ (Definition 2.71). Quadratic characters are named by a fundamental discriminant (Definition 2.67): for such D, $\chi_D(a) = \left(\frac{D}{a}\right)$ is (for $D \ne 1$) the character of $\mathbb{Q}(\sqrt{D})$ (Appendix B, B-C6(b)), primitive of conductor $|D|$ (Corollary 2.76); so $\chi_{-3} = \left(\frac{-3}{\cdot}\right)$ and $\chi_{-4} = \left(\frac{-4}{\cdot}\right)$. For a discriminant D that is not fundamental the Kronecker symbol $\left(\frac{D}{\cdot}\right)$ is always written out and never called χ_D: for instance $\left(\frac{-12}{\cdot}\right)$ is an imprimitive character modulo 12 that agrees with χ_{-3} at odd integers, whereas under B-C6(b) the symbol χ_{-12} would mean χ_{-3} itself, of conductor 3; the chapter does not use the symbol χ_{-12}. The letter D denotes a discriminant; as in the paper, $D = \prod_{q\in S} q$ is also the conductor of χ_S (the absolute value of the fundamental discriminant $\prod_{q\in S} q^*$). For an odd prime q put $q^* = (-1)^{(q-1)/2}q$; the quadratic character of conductor q is χ_{q^*}, never χ_q. Thus χ_{-7}, χ_{-11} are the characters of conductor 7, 11, while χ_5, χ_{13} have conductor 5, 13. A prime-letter subscript (χ_ℓ, χ_p) is reserved for the cyclotomic character (χ_D, χ_S, χ_{q^*} name quadratic characters): χ_ℓ is the ℓ-adic cyclotomic character of Chapter 5, $\bar{\chi}_\ell$ its reduction, written χ_3^{cyc}, $\bar{\chi}_3^{\mathrm{cyc}}$ at the prime 3; and $\omega_\ell\colon a \mapsto a \bmod \ell \in \mathbb{F}_\ell^\times$ is the Dirichlet character that corresponds to $\bar{\chi}_\ell$ (Chapters 5 and 6 make the correspondence). Two further names are not of this kind: χ_0 is the principal character modulo n, the standard name (the numeral 0 is not a discriminant, so it does not collide with B-C6(b)); and the p-component of a character χ, a character modulo a power of p, is written $\chi^{(p)}$ with a superscript (Proposition 2.75(v)), never χ_p, and members of a family of characters are written $\chi^{(i)}$ in the same way. The paper follows the same rules.

Convention 2.6 (roots of unity)**.** $\mu_n(K) = \{x \in K : x^n = 1\}$; $\zeta_n = e^{2\pi i/n} \in \mathbb{C}$; $\zeta_3 = (-1 + \sqrt{-3})/2$ with $\sqrt{-3} := 1 + 2\zeta_3 = i\sqrt{3}$. A primitive cube root of unity is always ζ_3, never ω (the letter ω is reserved for differentials and for the characters ω_ℓ). In this chapter π is the real number $3.14159\ldots$; the element $1 - \zeta_3$ is not given a name.

Definition 2.7. Let R be a ring. An element $a \in R$ is a *unit* if $ab = 1$ for some $b \in R$; the units form the group $R^\times$. A *zero divisor* is an $a \ne 0$ with $ab = 0$ for some $b \ne 0$; a is *nilpotent* if $a^n = 0$ for some $n \ge 1$. R is a *field* if $R \ne 0$ and $R^\times = R \setminus \{0\}$, and an *integral domain* (or *domain*) if $R \ne 0$ and R has no zero divisors. A *subring* is a subset containing 0 and 1 and closed under $+$, $-$, $\times$. A *homomorphism* $\phi\colon R \to S$ is a map with $\phi(a + b) = \phi(a) + \phi(b)$, $\phi(ab) = \phi(a)\phi(b)$, $\phi(1) = 1$; its *kernel* is $\phi^{-1}(0)$ and its *image* $\phi(R)$, a subring of S.

Example 2.8. $\mathbb{Z} \subset \mathbb{Q} \subset \mathbb{R} \subset \mathbb{C}$; $\mathbb{Z}/n\mathbb{Z}$; the polynomial ring $R[x]$ (Section 2.4); the product $R_1 \times R_2$ with componentwise operations, which has the zero divisors $(1,0)$ and $(0,1)$; the subring $\mathbb{Z}[i] = \{a + bi : a, b \in \mathbb{Z}\}$ of $\mathbb{C}$. If A is an abelian group, $\mathrm{End}_{\mathbb{Z}}(A)$ is a ring under addition and composition, in general non-commutative; a set of commuting endomorphisms generates a commutative subring. This is the shape of the Hecke algebra: the paper's $\mathbb{T}$ is "the subring of $\mathrm{End}\, S_2(\Gamma_0(N))$ generated over $\mathbb{Z}$ by all T_n" (Chapter 13). The element x of $\mathbb{Z}[x]/(x^2)$ is nilpotent; a domain has no nonzero nilpotents.

Proposition 2.9. *Let R be a ring.*

(i) There is exactly one homomorphism $\mathbb{Z} \to R$, namely $n \mapsto n \cdot 1$. Its kernel is $n\mathbb{Z}$ for a unique $n \geq 0$, called the characteristic $\mathrm{char}\, R$*; its image is isomorphic to $\mathbb{Z}/n\mathbb{Z}$.*

(ii) If R is a domain, $\mathrm{char}\, R$ *is 0 or a prime.*

(iii) A finite domain is a field.

Proof. (i) A homomorphism $\psi\colon \mathbb{Z} \to R$ has $\psi(1) = 1$, hence $\psi(n) = n \cdot 1$ for $n \geq 0$ by additivity and $\psi(-n) = -\psi(n)$; conversely $n \mapsto n \cdot 1$ is a homomorphism by the distributive law. The kernel is an ideal of $\mathbb{Z}$, hence of the form $n\mathbb{Z}$ with a unique $n \geq 0$ (Proposition 2.11(iii) below, whose proof uses only division with remainder), and the image is isomorphic to $\mathbb{Z}/n\mathbb{Z}$ by Theorem 2.12(i). (ii) Let $n = \mathrm{char}\, R > 0$. Since $R \neq 0$, $n \neq 1$. If $n = ab$ with $1 < a, b < n$, then $(a \cdot 1)(b \cdot 1) = 0$ with both factors nonzero (by minimality of n), which is impossible in a domain. So n is prime. (iii) Let R be a finite domain and $a \neq 0$. The map $x \mapsto ax$ is injective, because $ax = ay$ gives $a(x - y) = 0$, so $x = y$. An injective map of a finite set to itself is surjective, so $ab = 1$ for some b. □

For example $\mathrm{char}\, \mathbb{Z}/6\mathbb{Z} = 6$, and indeed $\mathbb{Z}/6\mathbb{Z}$ is not a domain: $2 \cdot 3 = 0$, exactly the factorisation used in (ii). The rings $\mathbb{F}_p[x]$ and $\mathbb{F}_p(x)$ have characteristic p and are infinite; $\mathbb{F}_p[x]$ is a domain that is not a field (x has no inverse, by degrees), so the finiteness in (iii) cannot be dropped. In the paper the Hecke algebra $\mathbb{T}$ has characteristic 0 (it contains $\mathbb{Z} \cdot T_1 = \mathbb{Z}$), while its quotients $\mathbb{T}/\mathfrak{m}$ by maximal ideals containing ℓ have characteristic ℓ.

Definition 2.10. An *ideal* of R is an additive subgroup I with $ra \in I$ for all $r \in R$, $a \in I$. The ideal generated by $a_1, \ldots, a_n$ is $(a_1, \ldots, a_n) = \{\sum r_i a_i\}$; an ideal (a) is *principal*. For ideals I, J: the sum $I + J = \{a + b\}$, the product IJ (the set of finite sums $\sum a_i b_i$, $a_i \in I$, $b_i \in J$) and the intersection $I \cap J$ are ideals; I and J are *comaximal* if $I + J = R$. For an R-module M (modules are Chapter 3; here M may be any abelian group on which R acts) and $S \subseteq M$, the *annihilator* is $\mathrm{Ann}_R(S) = \{r \in R : rs = 0 \text{ for all } s \in S\}$, an ideal. The *quotient ring* R/I is the quotient group with $(a + I)(b + I) = ab + I$; the projection $R \to R/I$ is a surjective homomorphism with kernel I.

The multiplication on R/I is well defined: if $a' = a + x$ and $b' = b + y$ with $x, y \in I$, then $a'b' - ab = ay + xb + xy \in I$. This computation is the reason for the definition: an additive subgroup I can serve as the set of elements declared to be 0 in a quotient ring exactly when it absorbs multiplication by all of R, since ay and xb must lie in I for arbitrary a, b. Small examples: in $\mathbb{Z}$, $(4, 6) = 2\mathbb{Z}$ and $4\mathbb{Z} \cdot 6\mathbb{Z} = 24\mathbb{Z} \subsetneq 4\mathbb{Z} \cap 6\mathbb{Z} = 12\mathbb{Z}$; the ideal $(2, x)$ of $\mathbb{Z}[x]$ is the set of polynomials with even constant term; $\mathrm{Ann}_{\mathbb{Z}}(\mathbb{Z}/6\mathbb{Z}) = 6\mathbb{Z}$, and for the $\mathbb{Z}$-module $M = \mathbb{Z}/4 \times \mathbb{Z}/6$ one has $\mathrm{Ann}_{\mathbb{Z}}(M) = 12\mathbb{Z}$; $2\mathbb{Z}$ and $3\mathbb{Z}$ are comaximal since $1 = 3 - 2$. The ideal $J = \mathrm{Ann}_{\mathbb{T}}(f^{\perp})$ of Lemma lem:crit is an annihilator of exactly this kind, with $R = \mathbb{T}$ acting on the module $f^{\perp}$.

Proposition 2.11. *(i) The kernel of a homomorphism is an ideal, and every ideal is the kernel of a homomorphism (the projection $R \to R/I$). An ideal I equals R iff it contains a unit. A ring is a field iff it is nonzero and its only ideals are 0 and R.*

(ii) $IJ \subseteq I \cap J$ for ideals I, J.

(iii) Every ideal of $\mathbb{Z}$ is $n\mathbb{Z}$ for a unique $n \geq 0$. For $m, n \in \mathbb{Z}$, $m\mathbb{Z} + n\mathbb{Z} = \gcd(m,n)\mathbb{Z}$, and $m\mathbb{Z} \cap n\mathbb{Z} = \operatorname{lcm}(m,n)\mathbb{Z}$.

Proof. (i) If $\phi(a) = \phi(b) = 0$ then $\phi(a-b) = 0$ and $\phi(ra) = \phi(r)\phi(a) = 0$. The projection has kernel I. If $u \in I$ is a unit, then $r = (ru^{-1})u \in I$ for every r. If R is a field, a nonzero ideal contains a unit, so it is R; conversely, if $R \neq 0$ has only the ideals 0 and R and $a \neq 0$, then $(a) = R \ni 1$, so a is a unit. (ii) Each $a_i b_i$ lies in I (as $a_i \in I$) and in J (as $b_i \in J$). (iii) Let $I \neq 0$ be an ideal of $\mathbb{Z}$ and n its least positive element. For $a \in I$ write $a = bn + r$ with $0 \leq r < n$; then $r = a - bn \in I$, so $r = 0$ by minimality. Hence $I = n\mathbb{Z}$; n is unique as the least positive element. Now $m\mathbb{Z} + n\mathbb{Z} = d\mathbb{Z}$ for some $d \geq 0$. Since $m, n \in d\mathbb{Z}$, d is a common divisor; since $d = um + vn$ for some u, v, every common divisor divides d. So $d = \gcd(m,n)$. Next, $m\mathbb{Z} \cap n\mathbb{Z}$ is an ideal (an intersection of ideals), so it is $e\mathbb{Z}$ for a unique $e \geq 0$. Since $e \in m\mathbb{Z} \cap n\mathbb{Z}$, e is a common multiple of m and n; and a common multiple c lies in $m\mathbb{Z} \cap n\mathbb{Z} = e\mathbb{Z}$, so $e \mid c$. A nonnegative common multiple that divides every common multiple is $\operatorname{lcm}(m,n)$ (with $\operatorname{lcm}(m,n) = 0$ when m or n is 0), so $e = \operatorname{lcm}(m,n)$. □

Theorem 2.12 (isomorphism theorems)**.** *Let $\phi\colon R \to S$ be a homomorphism and I an ideal of R.*

(i) ϕ induces an isomorphism $R/\ker\phi \simeq \phi(R)$.

(ii) (Correspondence.) $J \mapsto J/I$ is an inclusion-preserving bijection from the ideals of R containing I to the ideals of R/I, with inverse $\bar{J} \mapsto$ its preimage, and $(R/I)/(J/I) \simeq R/J$. Under it, prime ideals correspond to prime ideals and maximal ideals to maximal ideals (Theorem 2.17).

(iii) If ϕ is surjective with kernel I and J is any ideal of R, then $\phi(J)$ is an ideal of S and ϕ induces an isomorphism $R/(I+J) \simeq S/\phi(J)$.

(iv) Every quotient ring of $\mathbb{Z}$ is $\mathbb{Z}/r\mathbb{Z}$ for a unique $r \geq 0$; as an additive group it is cyclic, generated by the class of 1.

Proof. (i) The map $a + \ker\phi \mapsto \phi(a)$ is well defined and injective because $\phi(a) = \phi(b)$ iff $a - b \in \ker\phi$; it is additive, multiplicative and sends 1 to 1, and it is onto $\phi(R)$. (ii) For an ideal $\bar{J}$ of R/I its preimage J under the projection π is an ideal containing I with $\pi(J) = \bar{J}$, since π is onto. Conversely for $J \supseteq I$, $\pi(J) = J/I$ is an ideal of R/I (an additive subgroup, stable under multiplication by $\pi(r)$, as π is onto), and its preimage is $J + I = J$. Both maps preserve inclusions. The composite $R \to R/I \to (R/I)/(J/I)$ is onto with kernel $\pi^{-1}(J/I) = J$, so (i) gives $(R/I)/(J/I) \simeq R/J$. The statement on prime and maximal ideals follows from this isomorphism and Theorem 2.17(i): J is prime (maximal) iff R/J is a domain (a field) iff $(R/I)/(J/I)$ is. (iii) $\phi(J)$ is an additive subgroup, and for $s = \phi(r) \in S$ (every s is of this form) and $\phi(a) \in \phi(J)$, $s\phi(a) = \phi(ra) \in \phi(J)$. The composite $R \to S \to S/\phi(J)$ is onto, and a lies in its kernel iff $\phi(a) = \phi(b)$ for some $b \in J$, iff $a - b \in I$ for some $b \in J$, iff $a \in I + J$. Now apply (i). (iv) A quotient ring of $\mathbb{Z}$ is $\mathbb{Z}/I$ with $I = r\mathbb{Z}$, $r \geq 0$ unique (Proposition 2.11(iii)); every class is a multiple of the class of 1. □

Proposition 2.13. *Let I, J be ideals of a ring R. The sequence of additive groups (indeed of R-modules)*

$$0 \longrightarrow R/(I \cap J) \xrightarrow{x \mapsto (x,x)} R/I \times R/J \xrightarrow{(y,z) \mapsto y-z} R/(I+J) \longrightarrow 0 \tag{2.1}$$

is exact. Consequently:

(i) if $I \cap J = 0$, then $R \to R/I \times R/J$ is injective, and its cokernel is isomorphic to $R/(I+J)$;

(ii) (Chinese remainder theorem for two ideals) if $I + J = R$, then $I \cap J = IJ$ and $R/IJ \to R/I \times R/J$ is a ring isomorphism;

(iii) (general Chinese remainder theorem) if $I_1, \dots, I_k$ are pairwise comaximal, then the natural map $R/(I_1 \cdots I_k) \to \prod_i R/I_i$ is a ring isomorphism.

Proof. In (2.1) the first map is well defined (if $x \in I \cap J$ both components vanish) and the second also (the class of $y - z$ modulo $I + J$ does not change if y is moved by I or z by J). The first map is injective: $(x, x) = 0$ means $x \in I$ and $x \in J$. The composite is zero. If $y - z \in I + J$, say $y - z = a + b$ with $a \in I$, $b \in J$, then $x := y - a = z + b$ satisfies $x \equiv y \pmod I$ and $x \equiv z \pmod J$; so the kernel of the second map is the image of the first. The second map is onto, since $(y, 0) \mapsto y$. (i) is the case $I \cap J = 0$ read off from exactness. (ii) If $I + J = R$ write $1 = a + b$ with $a \in I$, $b \in J$. For $x \in I \cap J$, $x = xa + xb \in IJ$ (as $xa = ax \in JI$ and $xb \in IJ$); with Proposition 2.11(ii), $I \cap J = IJ$. Exactness with $R/(I + J) = 0$ shows that $R/IJ \to R/I \times R/J$ is bijective; it is a ring homomorphism because both coordinates are. (iii) Induction on k, the case $k = 2$ being (ii). For $k \geq 3$, I_1 and $I_2 \cdots I_k$ are comaximal: writing $1 = a_j + b_j$ with $a_j \in I_1$, $b_j \in I_j$ for $j \geq 2$, the product $\prod_{j \geq 2}(a_j + b_j) = 1$ is $b_2 \cdots b_k \in I_2 \cdots I_k$ plus terms in I_1. By (ii) and the induction hypothesis, $R/I_1 \cdots I_k \simeq R/I_1 \times R/I_2 \cdots I_k \simeq R/I_1 \times \prod_{j \geq 2} R/I_j$. □

The maps in (2.1) commute with multiplication by elements of R, which is why the sequence is one of R-modules and not only of groups. A worked case in $R = \mathbb{Z}$: for $I = 4\mathbb{Z}$, $J = 6\mathbb{Z}$ one has $I \cap J = 12\mathbb{Z}$ and $I + J = 2\mathbb{Z}$ (Proposition 2.11(iii)), and the sequence is

$$0 \longrightarrow \mathbb{Z}/12\mathbb{Z} \longrightarrow \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \longrightarrow \mathbb{Z}/2\mathbb{Z} \longrightarrow 0,$$

with maps $x \mapsto (x \bmod 4, x \bmod 6)$ and $(y, z) \mapsto (y - z) \bmod 2$. The orders are consistent, $12 \cdot 2 = 24 = 4 \cdot 6$, and the cokernel $\mathbb{Z}/2\mathbb{Z}$ measures the failure of the Chinese remainder theorem: a pair (y, z) comes from an integer iff $y \equiv z \pmod 2$. In (ii), the decomposition is computed by idempotents: for $I = 3\mathbb{Z}$, $J = 5\mathbb{Z}$, Bezout gives $1 = 2 \cdot 5 - 3 \cdot 3$, and $a = -9 \in I$, $b = 10 \in J$. The class of $b = 10$ is 1 modulo 3 and 0 modulo 5, and $-9 \equiv 6 \pmod{15}$ is 0 modulo 3 and 1 modulo 5; both are idempotents of $\mathbb{Z}/15\mathbb{Z}$ ($10^2 = 100 \equiv 10$, $6^2 = 36 \equiv 6$). So the pair $(y \bmod 3, z \bmod 5)$ comes from $10y + 6z \bmod 15$; for instance $(2, 3)$ comes from $38 \equiv 8 \pmod{15}$. This is the situation of Lemma lem:crit with the roles reversed: there $I \cap J = 0$ and the interesting group is the cokernel $R/(I + J)$, here it is $I + J = R$ and the cokernel vanishes.

Proposition 2.14. *An* idempotent *of R is an element e with $e^2 = e$.*

(i) If e is idempotent, so is $1 - e$, and $e(1 - e) = 0$. The set Re is a ring with identity e (not a subring of R unless $e = 1$), and $x \mapsto (xe, x(1-e))$ is a ring isomorphism $R \to Re \times R(1-e)$.

(ii) R is isomorphic to a product of two nonzero rings iff it has an idempotent $e \neq 0, 1$.

(iii) The ideals of $R_1 \times R_2$ are the products $I_1 \times I_2$ of ideals; its prime ideals are the $P_1 \times R_2$ and $R_1 \times P_2$ with P_i prime, and the same holds for maximal ideals.

(iv) If $f = f_1 \cdots f_k \in K[x]$ (K a field) with pairwise coprime f_i, then $K[x]/(f) \simeq \prod_i K[x]/(f_i)$. For instance $\mathbb{Q}[x]/(x^2 - x) \simeq \mathbb{Q} \times \mathbb{Q}$, $x \mapsto (0, 1)$.

Proof. (i) $(1-e)^2 = 1 - 2e + e^2 = 1 - e$ and $e(1-e) = e - e^2 = 0$. Re is closed under addition and multiplication, and $e \cdot xe = xe^2 = xe$, so e is its identity. The map $x \mapsto (xe, x(1-e))$ is additive and multiplicative ($xye = xe \cdot ye$ as $e^2 = e$) and sends 1 to $(e, 1-e)$, the identity of the product. It is injective, since $xe = x(1-e) = 0$ gives $x = xe + x(1-e) = 0$, and surjective, since $(ae, b(1-e))$ is the image of $ae + b(1-e)$ (use $e(1-e) = 0$). (ii) If $R = R_1 \times R_2$ with $R_i \neq 0$, then $e = (1, 0)$ is an idempotent different from 0 and 1. Conversely, given such e, (i) gives $R \simeq Re \times R(1-e)$ with $Re \ni e \neq 0$ and $R(1-e) \ni 1 - e \neq 0$. (iii) If I is an ideal of $R_1 \times R_2$, let I_1, I_2 be its projections; they are ideals. If $(a, b) \in I$ then $(a, 0) = (1, 0)(a, b) \in I$ and $(0, b) \in I$; so $I = I_1 \times I_2$. The quotient $(R_1 \times R_2)/(I_1 \times I_2) \simeq R_1/I_1 \times R_2/I_2$ is a domain (resp. a field) iff one factor is zero and the other a domain (resp. a field), because $(1, 0)(0, 1) = 0$; by Theorem 2.17(i) this gives the prime and maximal ideals. (iv) This part uses two results proved later: $K[x]$ is a principal ideal domain (PID, Definition 2.23), by Proposition 2.30(ii), and in a PID $(a) + (b) = (\gcd(a, b))$ (Theorem 2.25(ii)); neither proof uses this proposition. So coprime f_i, f_j satisfy $(f_i) + (f_j) = (\gcd(f_i, f_j)) = K[x]$, and $(f_1) \cdots (f_k) = (f)$; apply Proposition 2.13(iii). For $x^2 - x = x(x-1)$, the map is $g \mapsto (g(0), g(1))$, and the class of x is the idempotent $(0, 1)$. □

For example, in $R = \mathbb{Z}/6\mathbb{Z}$ the element $e = 3$ is idempotent ($9 \equiv 3$), with $1 - e = -2 \equiv 4$. Then $Re = \{0, 3\}$, a ring with identity 3 isomorphic to $\mathbb{Z}/2\mathbb{Z}$, and $R(1-e) = \{0, 4, 2\}$, a ring with identity 4 isomorphic to $\mathbb{Z}/3\mathbb{Z}$; the map of (i) is $x \mapsto (3x, 4x)$, and it recovers $\mathbb{Z}/6\mathbb{Z} \simeq \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. By (iii) the prime ideals of $\mathbb{Z}/6\mathbb{Z}$ are the two ideals $0 \times \mathbb{Z}/3\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times 0$, that is $2\mathbb{Z}/6\mathbb{Z} = \{0, 2, 4\}$ and $3\mathbb{Z}/6\mathbb{Z} = \{0, 3\}$, in accordance with the correspondence Theorem 2.12(ii). In the paper the idempotents are those of $\mathbb{T} \otimes \mathbb{Q}$ and $\mathbb{T} \otimes \mathbb{Z}_\ell$: $\mathbb{T} \otimes \mathbb{Q} = \mathbb{Q} \times \mathbb{T}'$ corresponds to the idempotent e projecting onto the factor $\mathbb{Q}$ (the action on the line spanned by f). The idempotent e itself need not lie in $\mathbb{T}$: in the ring $R = \{(a, b) \in \mathbb{Z}^2 : a \equiv b \pmod r\}$ of Exercise 2.91, the idempotent $e = (1, 0)$ of $R \otimes \mathbb{Q} = \mathbb{Q} \times \mathbb{Q}$ is not in R for $r > 1$, and the least positive integer m with $me = (m, 0) \in R$ is $m = r$, the order of $R/(I + J)$.

In the paper 2.15. Lemma lem:crit (congruence criterion) is ring theory once one fact about Hecke algebras is granted. Let $\phi_f \colon \mathbb{T} \to \mathbb{Z}$, $T_n \mapsto a_n(f)$, let $I = \ker \phi_f$ and $J = \mathrm{Ann}_{\mathbb{T}}(f^\perp)$. The paper writes $\mathbb{T} \otimes \mathbb{Q} = \mathbb{Q} \times \mathbb{T}'$, where the first factor is the action on the line $\mathbb{Q}f$ and $\mathbb{T}'$ the (faithful) action on $f^\perp$; that this decomposition exists is a statement about Hecke operators and the Petersson product (Chapter 13). Granting it, $\mathbb{T}$ embeds in $\mathbb{T} \otimes \mathbb{Q}$ ($\mathbb{T}$ is torsion-free) and $t \mapsto (\phi_f(t), t')$. Then $t \in I$ iff its first coordinate vanishes, so $I = \mathbb{T} \cap (0 \times \mathbb{T}')$; and $t \in J$ iff t kills $f^\perp$ iff $t' = 0$, so $J = \mathbb{T} \cap (\mathbb{Q} \times 0)$. Hence $I \cap J = 0$. The map ϕ_f is onto $\mathbb{Z}$ because $T_1 = 1$ and $\phi_f(T_1) = a_1(f) = 1$; by Theorem 2.12(iii),

$$\mathbb{T}/(I + J) \simeq \mathbb{Z}/\phi_f(J),$$

and this is cyclic (Theorem 2.12(iv)): "$\mathbb{T}/(I + J)$ is cyclic of order r; equivalently, r generates the congruence ideal $\phi_f(J) = \phi_f(\mathrm{Ann}_{\mathbb{T}} I)$". By Proposition 2.13(i), the inclusion $\mathbb{T} \subset \mathbb{T}/I \times \mathbb{T}/J$ has cokernel $\mathbb{T}/(I + J)$, which is the sentence "Dualising the inclusion $\mathbb{T} \subset \mathbb{T}/I \times \mathbb{T}/J$, whose cokernel is $\mathbb{T}/(I + J)$" of the proof. The module version of the same sequence, $L[\wp] \oplus L[I] \subseteq L$ in Lemma lem:ddt417, is Chapter 3. In Step 1 of the proof of Theorem thm:quant, and in Lemma

lem:hecke, $\mathbb{T}\otimes\mathbb{Z}_\ell$ is a product of local rings cut out by idempotents (Proposition 2.14; the general statement for finite $\mathbb{Z}_\ell$-algebras is Chapter 3).

Proposition 2.16. *Let R be a ring of prime characteristic p.*

(i) $p \mid \binom{p}{i}$ *for* $0 < i < p$*; hence* $(x+y)^p = x^p + y^p$ *and* $(x+y)^{p^k} = x^{p^k} + y^{p^k}$ *for* $x, y \in R$*,* $k \geq 0$*.*

(ii) $F\colon x \mapsto x^p$ *is a ring endomorphism of R (the* absolute Frobenius*). It is injective if R is a domain and bijective if R is a finite domain, that is (Proposition 2.9(iii)) a finite field.*

(iii) (Fermat) $a^p \equiv a \pmod{p}$ *for every* $a \in \mathbb{Z}$*.*

Proof. (i) $\binom{p}{i} = \frac{p!}{i!(p-i)!}$ is an integer; p divides the numerator and not the denominator when $0 < i < p$ (a prime dividing a product of integers smaller than p would divide one of them: Euclid's lemma, Proposition 2.26(ii) below, whose proof does not use this proposition). So the middle terms of the binomial expansion vanish in R. The case p^k follows by induction, applying the case p to $x^{p^{k-1}}$ and $y^{p^{k-1}}$. (ii) F is additive by (i) and multiplicative by commutativity, and $F(1) = 1$. In a domain $x^p = 0$ forces $x = 0$; an injective map of a finite set to itself is bijective. (iii) In $R = \mathbb{Z}/p\mathbb{Z}$, F is additive and fixes 1, so it fixes every $n \cdot 1$: $n^p \equiv n \pmod{p}$. □

2.2 Prime and maximal ideals, fractions, and the ring $\mathbb{Z}_{(p)}$

Prime and maximal ideals are how the paper speaks about reduction: a maximal ideal $\mathfrak{m}$ of $\mathbb{T}\otimes\mathbb{Z}_\ell$ "containing ℓ and $\ker\phi_f$" (Lemma lem:hecke, Theorem thm:quant) is a congruence modulo ℓ between f and other eigenforms, and the last step of Lemma lem:crit is that a maximal ideal of residue characteristic ℓ containing $I + J$ forces ℓ to divide $\#\mathbb{T}/(I+J)$. The ring $\mathbb{Z}_{(p)}$ of rationals with denominator prime to p is the first local ring of the book; it is where the paper's "nonzero rational number which is an ℓ-adic integer" (Lemma lem:fpr) lives.

Theorem 2.17. *An ideal $P \neq R$ is* prime *if $ab \in P$ implies $a \in P$ or $b \in P$; an ideal $M \neq R$ is* maximal *if the only ideals containing M are M and R.*

(i) R/P is a domain iff P is prime; R/M is a field iff M is maximal. Every maximal ideal is prime.

(ii) The preimage of a prime ideal under a homomorphism is prime. The kernel of a homomorphism $\phi\colon R \to K$ to a field is prime; it is maximal if ϕ is surjective, or more generally if $\phi(R)$ is finite.

(iii) If R/P is finite, then P is prime iff it is maximal.

(iv) The prime ideals of $\mathbb{Z}$ are 0 and the $p\mathbb{Z}$; the maximal ideals are the $p\mathbb{Z}$.

(v) Every nonzero ring has a maximal ideal; every non-unit of R lies in a maximal ideal.

Proof. (i) $R/P \neq 0$ iff $P \neq R$, and $\bar{a}\bar{b} = 0$ in R/P means $ab \in P$; so "no zero divisors" is "prime". By the correspondence Theorem 2.12(ii) the ideals of R/M are the J/M with $M \subseteq J$, so R/M has exactly two ideals iff M is maximal, and Proposition 2.11(i) says this means R/M is a field. A field is a domain. (ii) If $Q \subset S$ is prime and $\phi\colon R \to S$, then $\phi^{-1}(Q) \neq R$ (as $\phi(1) = 1 \notin Q$), and $ab \in \phi^{-1}(Q)$ gives $\phi(a)\phi(b) \in Q$. The zero ideal of a field is prime, so $\ker\phi$ is prime. By

(i) of Theorem 2.12, $R/\ker\phi \simeq \phi(R)$, a subring of a field, hence a domain; if it is all of K or finite, it is a field (Proposition 2.9(iii)), and $\ker\phi$ is maximal by (i). (iii) R/P is a finite ring; it is a domain iff it is a field (Proposition 2.9(iii)). (iv) A nonzero ideal of $\mathbb{Z}$ is $n\mathbb{Z}$ with $n \geq 1$ (Proposition 2.11); $\mathbb{Z}/n$ is a domain iff n is prime (Proposition 2.40(i) below, proved from Bezout's identity and independent of this theorem), and is then finite, hence a field. $\mathbb{Z}/0 = \mathbb{Z}$ is a domain and not a field. (v) Let a be a non-unit (for instance $a = 0$ in a nonzero ring). The set Σ of ideals $I \neq R$ containing a is nonempty, as $(a) \neq R$, and is partially ordered by inclusion. The union of a chain in Σ is an ideal containing a, and it does not contain 1 because no member does; so it lies in Σ. By Zorn's lemma Σ has a maximal element, which is a maximal ideal containing a. (For Noetherian rings, Definition 2.23 and Theorem 2.25(ii), Zorn's lemma can be avoided: a nonempty set of ideals then has a maximal element.) □

Examples: in $\mathbb{Z}[x]$, (x) is prime but not maximal, since $\mathbb{Z}[x]/(x) \simeq \mathbb{Z}$ (evaluation at 0) is a domain but not a field; it lies in the maximal ideal $(2, x)$, with $\mathbb{Z}[x]/(2, x) \simeq \mathbb{F}_2$. In $\mathbb{Z}$, (4) is not prime ($2 \cdot 2 \in (4)$). Part (ii) in its form "$\phi(R)$ finite" is the one used in the paper: the map $\mathbb{T} \to \mathcal{O}/\lambda$ of Paper link 2.19 need not be surjective, but its image is a subring of a finite field, hence a finite domain, hence a field.

Proposition 2.18. *Let $\mathfrak{m}$ be a maximal ideal of R such that the field $R/\mathfrak{m}$ has characteristic $\ell > 0$ (we say $\mathfrak{m}$ has* residue characteristic ℓ*).*

(i) $\ell \cdot 1 \in \mathfrak{m}$.

(ii) If $\mathfrak{a} \subseteq \mathfrak{m}$ is an ideal with $R/\mathfrak{a}$ finite, then $\ell \mid \#(R/\mathfrak{a})$.

(iii) For $r \geq 1$, there is a ring homomorphism $\mathbb{Z}/r\mathbb{Z} \to k$ into a field k of characteristic ℓ iff $\ell \mid r$.

Proof. (i) The image of $\ell \cdot 1$ in $R/\mathfrak{m}$ is $\ell \cdot 1 = 0$. (ii) The projection $R/\mathfrak{a} \to R/\mathfrak{m}$ is onto (Theorem 2.12(ii)), so $\#(R/\mathfrak{a}) = \#(\mathfrak{m}/\mathfrak{a}) \cdot \#(R/\mathfrak{m})$ by Lagrange's theorem for the additive group. The field $R/\mathfrak{m}$ contains $\mathbb{F}_\ell$ (the image of $\mathbb{Z}$) and is a vector space over it of dimension ≥ 1, finite as $R/\mathfrak{a}$ is; so $\#(R/\mathfrak{m})$ is a positive power of ℓ. (iii) A homomorphism $\mathbb{Z}/r \to k$ composed with $\mathbb{Z} \to \mathbb{Z}/r$ is the unique map $\mathbb{Z} \to k$ (Proposition 2.9), whose kernel is $\ell\mathbb{Z}$; it factors through $\mathbb{Z}/r$ iff $r\mathbb{Z} \subseteq \ell\mathbb{Z}$, i.e. iff $\ell \mid r$. □

In the paper 2.19. The last step of the proof of Lemma lem:crit reads: "Thus $I + J$ lies in the kernel of $\mathbb{T} \to \mathcal{O}/\lambda$, a maximal ideal of residue characteristic ℓ, and ℓ divides $\#\mathbb{T}/(I + J) = r$." Here the map $\mathbb{T} \to \mathcal{O}/\lambda$ is $t \mapsto \phi_f(t) \bmod \lambda$; its image is a subring of the finite field $\mathcal{O}/\lambda$ (whose characteristic is ℓ, as $\lambda \mid \ell$), so its kernel $\mathfrak{m}$ is maximal by Theorem 2.17(ii), of residue characteristic ℓ. It contains $I = \ker\phi_f$, and J because ϕ_g kills J and $\phi_g \equiv \phi_f \pmod{\lambda}$. Since $\mathbb{T}/(I + J) \simeq \mathbb{Z}/r$ is finite (if $r \neq 0$), Proposition 2.18(ii) gives $\ell \mid r$; equivalently, by (iii), $\mathbb{Z}/r$ maps to a field of characteristic ℓ. The same reasoning is behind "after enlarging $\mathcal{O}$ and λ" in Lemma lem:old.

Theorem 2.20. *Let R be a domain. On pairs $(a, b) \in R \times (R \setminus \{0\})$ put $(a, b) \sim (c, d)$ iff $ad = bc$, and write a/b for the class. Then* $\mathrm{Frac}(R) = \{a/b\}$ *with $a/b + c/d = (ad + bc)/bd$ and $(a/b)(c/d) = ac/bd$ is a field, $a \mapsto a/1$ is an injective homomorphism $R \to \mathrm{Frac}(R)$, and every injective homomorphism $\iota\colon R \to K$ into a field extends uniquely to a homomorphism* $\mathrm{Frac}(R) \to K$*, namely $a/b \mapsto \iota(a)\iota(b)^{-1}$. Examples:* $\mathrm{Frac}(\mathbb{Z}) = \mathbb{Q}$, $\mathrm{Frac}(F[x]) = F(x)$, $\mathrm{Frac}(\mathbb{Z}[i]) = \mathbb{Q}(i)$, $\mathrm{Frac}(\mathbb{Z}[\zeta_3]) = \mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$.

Proof. $\sim$ is reflexive and symmetric; if $ad = bc$ and $cf = de$ then $adf = bcf = bde$, so $d(af - be) = 0$ and $af = be$ as $d \neq 0$: it is transitive. The operations are well defined: if $ab' = a'b$, then $(ad + bc)b'd = a'bd^2 + bb'cd = (a'd + b'c)bd$ and $ac \cdot b'd = a'c \cdot bd$, so replacing (a, b) by (a', b') does not change the classes of $(ad + bc, bd)$ and (ac, bd) (by symmetry the same holds in the second argument). The ring axioms are checked by computing both sides, using that $(x, y) \sim (tx, ty)$ for $t \neq 0$; for instance for distributivity, $\frac{a}{b}(\frac{c}{d} + \frac{e}{f}) = \frac{a(cf+de)}{bdf}$ and $\frac{ac}{bd} + \frac{ae}{bf} = \frac{acbf+bdae}{b^2df} = \frac{b\cdot a(cf+de)}{b\cdot bdf}$, which are equal; associativity of the addition holds because both bracketings give $(adf + bcf + bde)/bdf$. Here $bd \neq 0$ because R is a domain, which is where the hypothesis is used: in $\mathbb{Z}/6\mathbb{Z}$ the would-be fraction $1/2 \cdot 1/3$ has denominator 0. A nonzero a/b has $a \neq 0$ and inverse b/a. The map $a \mapsto a/1$ is a homomorphism, injective since $a/1 = 0/1$ means $a = 0$. If ι is injective, $\iota(b) \neq 0$ for $b \neq 0$, so $a/b \mapsto \iota(a)\iota(b)^{-1}$ makes sense; it is well defined ($ad = bc$ gives $\iota(a)\iota(d) = \iota(b)\iota(c)$) and a homomorphism. Uniqueness: any extension $\tilde{\iota}$ satisfies $\tilde{\iota}(a/b)\iota(b) = \tilde{\iota}(a/b \cdot b/1) = \iota(a)$. For the examples: $\mathbb{Q}(i)$ and $\mathbb{Q}(\zeta_3)$ are fields containing $\mathbb{Z}[i]$ and $\mathbb{Z}[\zeta_3]$ in which every element is a quotient (for $z = x + yi \in \mathbb{Q}(i)$ clear the denominators of x, y); $\zeta_3 = (-1 + \sqrt{-3})/2$ gives $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$. □

Proposition 2.21. *Let p be a prime and $\mathbb{Z}_{(p)} = \{a/b \in \mathbb{Q} : a, b \in \mathbb{Z},\ p \nmid b\}$.*

(i) $\mathbb{Z}_{(p)}$ is a subring of $\mathbb{Q}$, and $\mathbb{Z}_{(p)}^\times = \{a/b : p \nmid ab\}$; an integer prime to p is a unit of $\mathbb{Z}_{(p)}$.

(ii) Every nonzero element is $p^k u$ with $k \geq 0$ and $u \in \mathbb{Z}_{(p)}^\times$, uniquely; the nonzero ideals are the $p^k\mathbb{Z}_{(p)}$, $k \geq 0$, and $p\mathbb{Z}_{(p)}$ is the only maximal ideal (so $\mathbb{Z}_{(p)}$ is a local ring*; it is the first example of a discrete valuation ring, Chapter 3).*

(iii) The reduction map $\mathbb{Z}_{(p)} \to \mathbb{F}_p$, $a/b \mapsto \bar{a}\bar{b}^{-1}$, is a well-defined surjective ring homomorphism with kernel $p\mathbb{Z}_{(p)}$; it maps $\mathbb{Z}_{(p)}^\times$ onto $\mathbb{F}_p^\times$.

(iv) $\mathbb{Z}_{(p)} = \{x \in \mathbb{Q} : v_p(x) \geq 0\}$ and $\mathbb{Z}_{(p)}^\times = \{x \in \mathbb{Q} : v_p(x) = 0\}$.

(v) $\mathbb{Z} = \bigcap_p \mathbb{Z}_{(p)}$.

Proof. Every rational is a/b in lowest terms with $b > 0$, and $x \in \mathbb{Z}_{(p)}$ iff p does not divide this b (if $x = a'/b'$ with $p \nmid b'$, the reduced denominator divides b'). (i) Sums and products of fractions with denominators prime to p have denominators bd prime to p (Euclid's lemma, Proposition 2.26). In lowest terms, a/b has an inverse b/a in $\mathbb{Z}_{(p)}$ iff $p \nmid a$. (ii) Write $a = p^k a'$ with $p \nmid a'$ (unique factorisation in $\mathbb{Z}$); then $a/b = p^k \cdot a'/b$ with a'/b a unit, and $k = v_p(a/b)$ is determined (Definition 2.81). If $I \neq 0$ is an ideal, let k be the least exponent of its elements; then $p^k = (p^k u)u^{-1} \in I$ and every element $p^{k'}u'$ of I, $k' \geq k$, lies in $p^k\mathbb{Z}_{(p)}$; so $I = p^k\mathbb{Z}_{(p)}$. These ideals form a chain, and the largest proper one is $p\mathbb{Z}_{(p)}$, which is the set of non-units. (iii) If $p \nmid b$ then $\bar{b} \in \mathbb{F}_p^\times$; if $a/b = a'/b'$ then $ab' = a'b$, so $\bar{a}\bar{b}^{-1} = \bar{a}'\bar{b}'^{-1}$. Additivity and multiplicativity follow from the formulas for fractions. It is onto because it restricts to $\mathbb{Z} \to \mathbb{F}_p$. Its kernel is $\{a/b : p \mid a\} = p\mathbb{Z}_{(p)}$, and units map to units. (iv) is (i) and (ii) rewritten with v_p. (v) A rational in lowest terms a/b with $b > 1$ is not in $\mathbb{Z}_{(p)}$ for any prime $p \mid b$. □

For example, in $\mathbb{Z}_{(5)}$ the element $\frac{1}{2}$ is a unit and reduces to $\bar{2}^{-1} = 3 \in \mathbb{F}_5$ (as $2 \cdot 3 = 6 \equiv 1$); the element $\frac{10}{3} = 5 \cdot \frac{2}{3}$ has $v_5 = 1$ and reduces to 0; and $\frac{1}{5} \notin \mathbb{Z}_{(5)}$, so it has no reduction. The word *local* refers to the fact that $\mathbb{Z}_{(p)}$ only sees the prime p: every other prime has become a unit, and the non-units form the single ideal $p\mathbb{Z}_{(p)}$. This is the setting of every statement of the form "x is an ℓ-adic integer": it means $x \in \mathbb{Z}_{(\ell)}$, i.e. ℓ does not divide the reduced denominator of x.

In the paper 2.22. In Lemma lem:fpr, "$L_p(A_f,1)^{-1} = L_p(A_f(1),0)^{-1}$ is a nonzero rational number which is an ℓ-adic integer" means: it lies in $\mathbb{Z}_{(\ell)}$ (Chapters 3 and 7 replace $\mathbb{Z}_{(\ell)}$ by $\mathbb{Z}_\ell$, and $\mathbb{Z}_{(\ell)} = \mathbb{Q} \cap \mathbb{Z}_\ell$). Indeed $L_p(A_f,1)^{-1} = P_p(p^{-2})$ with $P_p \in \mathbb{Z}[X]$, a rational whose denominator is a power of $p \neq \ell$, and p is a unit of $\mathbb{Z}_{(\ell)}$ by Proposition 2.21(i); see Lemma 2.86. The same remark gives sense to Definition def:terms (q is an ℓ-adic unit, so $v_\ell(1 - a_q^2 q^{-2})$ and $v_\ell(P_q(q^{-2}))$ are valuations of elements of $\mathbb{Z}_{(\ell)}$). In Lemma lem:tamfactor, the class $c(u)$ of the reduction of u is computed from the image of the unit $u = q_E q^{-n} \in \mathbb{Z}_q^\times$ under the reduction map, of which Proposition 2.21(iii) is the rational version; Chapter 7 gives the reduction $\mathbb{Z}_q \to \mathbb{F}_q$.

2.3 Euclidean domains, PIDs and UFDs; the rings $\mathbb{Z}[i]$ and $\mathbb{Z}[\zeta_3]$

This section proves unique factorisation where the book needs it: in $\mathbb{Z}$ (the ℓ-part of an integer, used in every statement of the paper about $v_\ell(\deg \varphi_E)$), in $F[x]$ (minimal polynomials, finite fields), and in the rings $\mathbb{Z}[i]$ and $\mathbb{Z}[\zeta_3]$ of Gaussian and Eisenstein integers, whose characters χ_{-4} and χ_{-3} appear in the table of Section 1 and whose ℓ-adic versions $\mathbb{Z}_\ell \otimes \mathbb{Z}[\zeta_3]$ (a product of two copies of $\mathbb{Z}_\ell$, so not a domain, when $\ell \equiv 1 \pmod 3$) and $\mathbb{Z}_3[\zeta_3]$ appear in the proofs of Lemmas lem:euler and lem:IV. The primes of $\mathbb{Z}[i]$ and $\mathbb{Z}[\zeta_3]$, the element $1 - \zeta_3$ as a uniformiser and the ring $\mathbb{Z}_3[\zeta_3]$ are treated in Chapter 6.

Definition 2.23. Let R be a domain. For $a, b \in R$, $a \mid b$ if $b = ac$ for some c; a and b are *associates* if $b = ua$ with $u \in R^\times$. A nonzero non-unit a is *irreducible* if $a = bc$ implies that b or c is a unit, and *prime* if $a \mid bc$ implies $a \mid b$ or $a \mid c$. A *greatest common divisor* of a and b is a common divisor divisible by every common divisor (unique up to units if it exists). R is

- a *Euclidean domain* if there is $N\colon R \setminus \{0\} \to \mathbb{Z}_{\geq 0}$ such that for all a and all $b \neq 0$ there are $\kappa, \rho \in R$ with $a = \kappa b + \rho$ and $\rho = 0$ or $N(\rho) < N(b)$;
- a *principal ideal domain* (PID) if every ideal is principal;
- a *unique factorisation domain* (UFD) if every nonzero non-unit is a product of irreducibles, uniquely up to order and associates.

A ring is *Noetherian* if every ascending chain of ideals $I_1 \subseteq I_2 \subseteq \cdots$ is eventually constant.

Lemma 2.24. *Let R be a domain.*

(i) A prime element is irreducible.

(ii) For $a \neq 0$, the ideal (a) is prime iff a is a prime element.

(iii) If $p_1 \cdots p_r = u q_1 \cdots q_s$ with p_i, q_j prime elements and u a unit, then $r = s$ and, after renumbering, q_i is an associate of p_i for every i.

Proof. (i) If $p = bc$ is prime then $p \mid bc$, say $p \mid b$, $b = pt$; then $p = ptc$, so $tc = 1$ and c is a unit. (ii) $ab \in (a')$ means $a' \mid ab$; $(a') \neq R$ means a' is not a unit. So the definitions coincide. (iii) Induction on r. If $r = 0$ the right side is a unit, so $s = 0$ (a prime is not a unit). Otherwise p_1 divides $u q_1 \cdots q_s$, hence some q_j (it does not divide u); $q_j = p_1 t$ with t a unit by (i). Renumber so $j = 1$, cancel p_1 (in a domain $p_1 x = p_1 y$ gives $x = y$), and apply induction to $p_2 \cdots p_r = (ut) q_2 \cdots q_s$. □

Theorem 2.25. *(i) A Euclidean domain is a PID.*

(ii) A PID is Noetherian and a UFD. In a PID: $\gcd(a,b)$ *exists, with* $(a,b)=(\gcd(a,b))$ *(Bezout's identity); irreducible elements are prime; nonzero prime ideals are maximal.*

(iii) In a UFD irreducible elements are prime, and greatest common divisors exist.

(iv) $\mathbb{Z}$ *(with* $N(a)=|a|$*) and* $F[x]$ *for a field* F *(with* $N=\deg$*, Proposition 2.30) are Euclidean.* $\mathbb{Z}[x]$ *and* $F[x,y]$ *are UFDs (Theorem 2.32) but not PIDs:* $(2,x)\subset\mathbb{Z}[x]$ *and* $(x,y)\subset F[x,y]$ *are not principal.*

Proof. (i) Let $I\neq 0$ be an ideal and $b\in I\setminus\{0\}$ with $N(b)$ minimal. For $a\in I$ write $a=\kappa b+\rho$; then $\rho=a-\kappa b\in I$, so $\rho=0$ by minimality. Hence $I=(b)$. (ii) Let $I_1\subseteq I_2\subseteq\cdots$ be ideals of a PID. The union is an ideal, (a) say; a lies in some I_n, and then $I_m=(a)$ for $m\geq n$. For a,b write $(a,b)=(d)$; d divides a and b, and $d=ua+vb$ is divisible by every common divisor, so $d=\gcd(a,b)$. Let p be irreducible with $p\mid ab$ and $p\nmid a$. Then $\gcd(p,a)$ divides p, so it is a unit or an associate of p; the latter would give $p\mid a$. So $1=up+va$ and $b=upb+vab$ is divisible by p: p is prime. If $(p)\neq 0$ is prime and $(p)\subseteq(m)\neq R$, then $p=mt$, and as p is irreducible (Lemma 2.24) and m is not a unit, t is a unit and $(m)=(p)$; so (p) is maximal. Existence of factorisations: suppose a nonzero non-unit a_0 is not a product of irreducibles. Then a_0 is not irreducible, so $a_0=bc$ with b,c non-units, and one of them, a_1 say, is not a product of irreducibles; $(a_0)\subsetneq(a_1)$ because the cofactor is not a unit. Repeating gives a strictly increasing chain $(a_0)\subsetneq(a_1)\subsetneq\cdots$, which is impossible. Uniqueness follows from Lemma 2.24(iii), since irreducibles are prime. (iii) Let p be irreducible with $p\mid ab$, $ab=pc$. Factoring a, b, c into irreducibles, the two factorisations (factors of a)(factors of b) and p(factors of c) of ab agree up to order and units, so p is an associate of an irreducible factor of a or of b. For gcds, fix one irreducible p in each class of associates, write $a=u\prod p^{e_p(a)}$, $b=u'\prod p^{e_p(b)}$, and take $\prod p^{\min(e_p(a),e_p(b))}$: by uniqueness, $d\mid a$ iff $e_p(d)\leq e_p(a)$ for all p. (iv) Division with remainder in $\mathbb{Z}$ is $a=\kappa b+\rho$ with $0\leq\rho<|b|$; in $F[x]$ it is Proposition 2.30(i), as every nonzero polynomial over a field is a unit times a monic one. If $(2,x)=(d)$ in $\mathbb{Z}[x]$, then $d\mid 2$ forces $\deg d=0$, and $d\mid x$ forces $d=\pm1$; but then $1=2g+xh$, and evaluating at $x=0$ gives $1=2g(0)$ in $\mathbb{Z}$, impossible. If $(x,y)=(d)$ in $F[x,y]$, then d divides x and y, so it is a nonzero constant, and $1=xg+yh$ evaluated at $(0,0)$ gives $1=0$. □

Proposition 2.26. *(i) (Bezout) For* $m,n\in\mathbb{Z}$ *there are* $u,v\in\mathbb{Z}$ *with* $um+vn=\gcd(m,n)$.

(ii) (Euclid's lemma) If a prime p *divides* ab*, it divides* a *or* b.

(iii) (Fundamental theorem of arithmetic) Every $n\neq 0$ *is* $n=\pm\prod_p p^{v_p(n)}$ *with unique exponents* $v_p(n)\geq 0$*, almost all zero.*

(iv) $d\mid n$ *iff* $v_p(d)\leq v_p(n)$ *for all* p*; hence* $\gcd(m,n)=\prod_p p^{\min(v_p(m),v_p(n))}$ *and* $\operatorname{lcm}(m,n)=\prod_p p^{\max(v_p(m),v_p(n))}$ *for* $m,n\neq 0$*. The* p-part *of* $n\neq 0$ *is* $p^{v_p(n)}$.

Proof. $\mathbb{Z}$ is Euclidean, hence a PID (Theorem 2.25). (i) is Bezout's identity there (or Proposition 2.11(iii)); (ii) says that irreducible elements of $\mathbb{Z}$, the $\pm p$, are prime; (iii) is unique factorisation, the units being ±1 and the positive primes a system of representatives of the irreducibles. (iv) follows from (iii) as in the proof of Theorem 2.25(iii). □

Theorem 2.27. *Let* R *be* $\mathbb{Z}[i]=\{a+bi:a,b\in\mathbb{Z}\}$ *or* $\mathbb{Z}[\zeta_3]=\{a+b\zeta_3:a,b\in\mathbb{Z}\}$*, subrings of* $\mathbb{C}$ *(note* $\zeta_3^2=-1-\zeta_3$*), and* $N(z)=z\bar{z}=|z|^2$*. Then* $N(a+bi)=a^2+b^2$ *and* $N(a+b\zeta_3)=a^2-ab+b^2$ *are nonnegative integers, zero only at* 0*, and* $N(zw)=N(z)N(w)$.

(i) *For $\alpha, \beta \in R$, $\beta \neq 0$, there is $\kappa \in R$ with $N(\alpha - \kappa\beta) \leq \frac{1}{2}N(\beta)$ if $R = \mathbb{Z}[i]$, and $\leq \frac{1}{3}N(\beta)$ if $R = \mathbb{Z}[\zeta_3]$. Hence both rings are Euclidean for N, so PIDs and UFDs.*

(ii) *$z \in R$ is a unit iff $N(z) = 1$; $\mathbb{Z}[i]^\times = \{\pm 1, \pm i\} = \mu_4$ and $\mathbb{Z}[\zeta_3]^\times = \{\pm 1, \pm\zeta_3, \pm\zeta_3^2\} = \mu_6$.*

(iii) *An element of prime norm is irreducible, hence prime.*

(iv) *$2 = -i(1+i)^2$, $5 = (2+i)(2-i)$, $3 = -\zeta_3^2(1-\zeta_3)^2$, $7 = (3+\zeta_3)(3+\zeta_3^2)$, $13 = (4+\zeta_3)(4+\zeta_3^2)$, the factors being primes.*

Proof. Both sets are closed under multiplication ($i^2 = -1$; $\zeta_3^2 = -1 - \zeta_3$ because $\zeta_3 \neq 1$ is a root of $x^3 - 1 = (x-1)(x^2+x+1)$) and under complex conjugation ($\bar{\zeta_3} = \zeta_3^2$). $N(a + b\zeta_3) = a^2 + ab(\zeta_3 + \bar{\zeta_3}) + b^2 = a^2 - ab + b^2$. Multiplicativity is that of $|\cdot|^2$. (i) Put $\gamma = \alpha/\beta \in \mathbb{C}$. It suffices to find $\kappa \in R$ with $|\gamma - \kappa|^2 \leq \frac{1}{2}$, resp. $\frac{1}{3}$, and then $N(\alpha - \kappa\beta) = |\gamma - \kappa|^2 N(\beta)$. In the first case R is the square lattice, and $\mathbb{C}$ is tiled by the closed unit squares with vertices in R. In the second, the parallelograms with vertices $\kappa, \kappa+1, \kappa+\zeta_3, \kappa+1+\zeta_3$ ($\kappa \in R$) tile $\mathbb{C}$, and the diagonal from κ to $\kappa + 1 + \zeta_3 = \kappa - \zeta_3^2$ cuts each into two equilateral triangles of side 1 (all sides have length $|1| = |\zeta_3| = |1 + \zeta_3| = 1$). So γ lies in a square of side 1, resp. an equilateral triangle of side 1, with vertices in R. Join the centre c (of the square, resp. the centroid of the triangle) to the midpoints of the sides: this cuts the polygon into convex quadrilaterals, one at each vertex w, with corners w, two half-sides and c. The distance to w is a convex function, so on such a quadrilateral it is maximal at a corner; the corners are at distance 0, $\frac{1}{2}$, $\frac{1}{2}$ and $|c - w|$, which is $\frac{\sqrt{2}}{2}$ for the square and the circumradius $\frac{1}{\sqrt{3}}$ for the triangle. Hence $|\gamma - w|^2 \leq \frac{1}{2}$, resp. $\frac{1}{3}$, for the vertex w of the piece containing γ; take $\kappa = w$. The bound is attained at the centre, resp. the centroid. By Theorem 2.25, both rings are PIDs and UFDs. (ii) If $zw = 1$ then $N(z)N(w) = 1$ with both positive integers, so $N(z) = 1$; conversely $N(z) = 1$ gives $z \cdot \bar{z} = 1$ with $\bar{z} \in R$. Now $a^2 + b^2 = 1$ has the solutions $(\pm 1, 0)$, $(0, \pm 1)$; and $a^2 - ab + b^2 = 1$, i.e. $(2a - b)^2 + 3b^2 = 4$, forces $b \in \{0, \pm 1\}$ and gives $(a, b) = (\pm 1, 0)$, $(0, 1)$, $(1, 1)$, $(0, -1)$, $(-1, -1)$, that is ± 1, ζ_3, $1 + \zeta_3 = -\zeta_3^2$, $-\zeta_3$, $-1 - \zeta_3 = \zeta_3^2$. These are the six sixth roots of unity, $-\zeta_3$ having order 6. (iii) If $z = xy$ with $N(z)$ prime, one of $N(x)$, $N(y)$ is 1. In a PID irreducibles are prime. (iv) Direct multiplication: $(1 + i)^2 = 2i$; $(1 - \zeta_3)^2 = 1 - 2\zeta_3 + \zeta_3^2 = -3\zeta_3$, so $-\zeta_3^2(1 - \zeta_3)^2 = 3\zeta_3^3 = 3$; $(3 + \zeta_3)(3 + \zeta_3^2) = 9 + 3(\zeta_3 + \zeta_3^2) + 1 = 7$; $(4 + \zeta_3)(4 + \zeta_3^2) = 16 - 4 + 1 = 13$. The norms of the factors are $2, 5, 5, 3, 7, 7, 13, 13$, prime, so the factors are prime by (iii). □

Example 2.28 (the Euclidean algorithm in $\mathbb{Z}[i]$)**.** To compute $\gcd(11 + 3i, 1 + 8i)$ (norms 130 and 65): $\frac{11+3i}{1+8i} = \frac{(11+3i)(1-8i)}{65} = \frac{35-85i}{65}$, nearest Gaussian integer $1 - i$, and $11 + 3i = (1 - i)(1 + 8i) + (2 - 4i)$ with $N(2 - 4i) = 20 < 65$. Next $\frac{1+8i}{2-4i} = \frac{(1+8i)(2+4i)}{20} = \frac{-30+20i}{20}$, take $-2 + i$: $1 + 8i = (-2 + i)(2 - 4i) + (1 - 2i)$, $N(1 - 2i) = 5 < 20$. Finally $2 - 4i = 2(1 - 2i)$. So $\gcd(11 + 3i, 1 + 8i) = 1 - 2i$, of norm 5, up to units. Although 13 divides both norms, the factorisations $11 + 3i = (1 - 2i)(1 + i)(3 + 2i)$ and $1 + 8i = -(1 - 2i)(3 - 2i)$ show that different primes of norm 13 occur: $13 = (3 + 2i)(3 - 2i)$, and $3 - 2i$ is not an associate of $3 + 2i$.

Example 2.29 (unique factorisation fails in general)**.** In $\mathbb{Z}[\sqrt{-5}] = \{a + b\sqrt{-5}\}$, with $N(a + b\sqrt{-5}) = a^2 + 5b^2$, one has $6 = 2 \cdot 3 = (1 + \sqrt{-5})(1 - \sqrt{-5})$. The four factors have norms 4, 9, 6, 6; no element has norm 2 or 3, so each factor is irreducible; the units are ± 1 (norm 1), so no two of the factors are associates. Thus $\mathbb{Z}[\sqrt{-5}]$ is not a UFD, hence not a PID; explicitly, $(2, 1 + \sqrt{-5})$ is not principal: it lies in the kernel of the homomorphism $\mathbb{Z}[\sqrt{-5}] \to \mathbb{F}_2$, $a + b\sqrt{-5} \mapsto a + b \bmod 2$ (well defined since $\mathbb{Z}[\sqrt{-5}] \simeq \mathbb{Z}[x]/(x^2 + 5)$ and $1^2 + 5 = 0$ in $\mathbb{F}_2$), so it is proper, while a generator

d would have $N(d) \mid \gcd(4,6) = 2$, so $N(d) = 1$ and the ideal would be everything. Similarly $4 = 2 \cdot 2 = (1+\sqrt{-3})(1-\sqrt{-3})$ in $\mathbb{Z}[\sqrt{-3}] \subsetneq \mathbb{Z}[\zeta_3]$, with three non-associate irreducibles of norm 4; in $\mathbb{Z}[\zeta_3]$ the anomaly disappears because $1+\sqrt{-3} = 2+2\zeta_3 = -2\zeta_3^2$ is an associate of 2. The ideal-theoretic repair is Chapter 6.

2.4 Polynomial rings and irreducibility

Polynomials enter the paper as characteristic polynomials of Frobenius ($X^2 - a_p X + p$), as the Euler factors $P_q(X) \in \mathbb{Z}[X]$ of Definition def:terms, as the 3-division polynomial of Proposition prop:ns, and, behind the scenes, through finite fields and cyclotomic polynomials. This section proves division with remainder, the criterion for repeated roots, Gauss's lemma, the criteria of Eisenstein and of reduction modulo p, and Kronecker's construction of a field in which a given polynomial has a root. The input that a polynomial of degree d over a field has at most d roots (Proposition 2.30(iv)) is what Chapter 1 uses to prove that finite subgroups of $K^\times$ are cyclic.

Proposition 2.30. *Let R be a ring and $R[x]$ the polynomial ring;* $\deg 0 = -\infty$.

(i) (Division by a monic polynomial.) If $g \in R[x]$ is monic of degree m, every $f \in R[x]$ is uniquely $f = hg + r$ with $\deg r < m$.

(ii) If R is a domain, $\deg fg = \deg f + \deg g$, *$R[x]$ is a domain and $R[x]^\times = R^\times$. If F is a field, $F[x]$ is Euclidean for the degree, hence a PID and a UFD, and its maximal ideals are the (f) with f irreducible.*

(iii) (Factor theorem.) For $a \in R$, $f(a) = 0$ iff $(x-a) \mid f$.

(iv) A nonzero polynomial of degree d over a domain R has at most d roots in R.

(v) $x^p - x \in \mathbb{F}_p[x]$ is nonzero but vanishes at every point of $\mathbb{F}_p$; over an infinite domain a polynomial is determined by its values.

Proof. (i) Existence by induction on $\deg f$: if $\deg f = n \geq m$ with leading coefficient a, then $f - ax^{n-m}g$ has degree $< n$. Uniqueness: if $hg + r = h'g + r'$ with $h \neq h'$, then $(h-h')g = r' - r$; as g is monic, the left side has degree $\deg(h-h') + m \geq m > \deg(r'-r)$. (ii) The leading coefficient of fg is the product of those of f and g, nonzero in a domain. If $fg = 1$ then $\deg f = \deg g = 0$. Over a field every nonzero g is a unit times a monic polynomial, so (i) gives the Euclidean property; then Theorem 2.25 applies. A nonzero prime ideal of a PID is maximal, (f) is prime iff f is irreducible (Lemma 2.24, Theorem 2.25(ii)), and 0 is not maximal since $F[x]$ is not a field. (iii) Divide by the monic $x - a$: $f = h \cdot (x-a) + r$ with r constant; evaluating at a gives $r = f(a)$. (iv) Induction on d. If $f(a) = 0$ then $f = (x-a)h$ with $\deg h = d - 1$, and a root $b \neq a$ of f satisfies $(b-a)h(b) = 0$, so $h(b) = 0$. (v) $a^p = a$ for $a \in \mathbb{F}_p$ (Proposition 2.16(iii)). Over an infinite domain, two polynomials with the same values differ by a polynomial with infinitely many roots, which is 0 by (iv). □

Proposition 2.31. *The formal derivative of $f = \sum a_i x^i$ is $f' = \sum i a_i x^{i-1}$; it is additive and $(fg)' = f'g + fg'$. Let F be a field, $f \in F[x]$ nonzero and $K \supseteq F$ a field.*

(i) $a \in K$ is a multiple root of f (that is, $(x-a)^2 \mid f$ in $K[x]$) iff $f(a) = f'(a) = 0$.

(ii) The gcd of f and f' is the same in $F[x]$ and in $K[x]$; f has no repeated root in any extension field iff $\gcd(f, f') = 1$ *(we then call f* separable*).*

(iii) In characteristic p, $x^{p^r}-x$ is separable. For $n\geq 1$, x^n-1 is separable over F iff $\operatorname{char} F\nmid n$.

Proof. The Leibniz rule holds for monomials, $(x^{m+n})'=(m+n)x^{m+n-1}=mx^{m-1}x^n+x^m nx^{n-1}$, and extends by bilinearity. (i) If $f(a)=0$ write $f=(x-a)g$; then $f'=g+(x-a)g'$ and $f'(a)=g(a)$, which vanishes iff $(x-a)\mid g$. (ii) Let $d=\gcd(f,f')$ in $F[x]$, $d=uf+vf'$. Then d divides f, f' in $K[x]$, and every common divisor in $K[x]$ divides d; so d is also the gcd in $K[x]$. If f has a multiple root a in some K, then $x-a$ divides f and f' in $K[x]$, so $d\neq 1$. If d is nonconstant, it has a root a in some extension K (Theorem 2.38(iii)), and $f(a)=f'(a)=0$. (iii) $(x^{p^r}-x)'=p^r x^{p^r-1}-1=-1$. If $p=\operatorname{char} F\nmid n$, a common root of x^n-1 and nx^{n-1} would be 0, which is not a root of x^n-1. If $p\mid n$, the derivative is 0 and $x^n-1=(x^{n/p}-1)^p$ by Proposition 2.16. □

Theorem 2.32 (Gauss's lemma)**.** *Let R be a UFD with fraction field K. The* content *$c(f)$ of a nonzero $f\in R[x]$ is a gcd of its coefficients (defined up to units), and f is* primitive *if $c(f)$ is a unit. Every nonzero $g\in K[x]$ is $g=cg_1$ with $c\in K^\times$ and $g_1\in R[x]$ primitive, and c is unique up to $R^\times$.*

(i) $c(fg)=c(f)c(g)$ up to units; a product of primitive polynomials is primitive.

(ii) If $f\in R[x]$ factors as $f=gh$ in $K[x]$, then $f=g_1h_1$ in $R[x]$ with $g_1\in K^\times g$ and $h_1\in K^\times h$. Hence a primitive f of positive degree is irreducible in $R[x]$ iff it is irreducible in $K[x]$.

(iii) $R[x]$ is a UFD. Its prime elements are the primes of R and the primitive polynomials of positive degree irreducible in $K[x]$. Consequently $\mathbb{Z}[x_1,\dots,x_n]$ and $F[x_1,\dots,x_n]$ (F a field) are UFDs.

(iv) A monic $f\in\mathbb{Z}[x]$ which is a product of monic polynomials in $\mathbb{Q}[x]$ has those factors in $\mathbb{Z}[x]$. If a/b in lowest terms is a root of $a_nx^n+\cdots+a_0\in\mathbb{Z}[x]$, then $b\mid a_n$ and $a\mid a_0$; a rational root of a monic integer polynomial is an integer.

Proof. For $g\in K[x]$, multiply by a common denominator $b\in R$ and write $bg=c(bg)g_1$; then $g=(c(bg)/b)g_1$. If $cg_1=c'g_1'$ with g_1,g_1' primitive, write $c/c'=a/b$ with $a,b\in R$; then $ag_1=bg_1'$, and taking contents $a=b\cdot$unit, so $c/c'\in R^\times$. (i) Suppose f, g are primitive and fg is not. Some irreducible, hence prime (Theorem 2.25(iii)), $p\in R$ divides every coefficient of fg. Reduce modulo p: R/p is a domain (Lemma 2.24(ii)), so $(R/p)[x]$ is a domain, and $\bar f\bar g=0$ with $\bar f\neq 0\neq\bar g$, a contradiction. In general write $f=c(f)f_1$, $g=c(g)g_1$ with f_1,g_1 primitive; then $fg=c(f)c(g)f_1g_1$ with f_1g_1 primitive, so the gcd of the coefficients of fg is $c(f)c(g)$ times the gcd of those of f_1g_1, a unit: $c(fg)=c(f)c(g)$ up to units. (For instance $(2x+2)(3x+3)=6x^2+12x+6$ has content $6=2\cdot 3$.) (ii) Write $g=cg_1$, $h=c'h_1$ with g_1,h_1 primitive. Then $f=(cc')g_1h_1$ with g_1h_1 primitive by (i), and also $f=c(f)f_1$; by uniqueness, $cc'=c(f)u$ with $u\in R^\times$, so $cc'\in R$. Put $g_1':=cc'g_1\in R[x]$; then $f=g_1'h_1$. For the last claim: if f is primitive and $f=gh$ in $R[x]$ with g a non-unit, then g is not a constant (a constant factor divides $c(f)$, a unit), so a factorisation in $R[x]$ into non-units has both factors of positive degree; and a factorisation in $K[x]$ into factors of positive degree gives one in $R[x]$ with the same degrees. (iii) Existence: write $f=c(f)f_1$ and factor $c(f)$ in R. If the primitive f_1 is not irreducible, $f_1=gh$ with g,h non-units, necessarily of positive degree as just seen and primitive (as $c(g)c(h)=c(f_1)$ is a unit); induction on the degree. Primes: if p is prime in R, then $R[x]/pR[x]\simeq(R/p)[x]$ is a domain, so p is prime in $R[x]$. If f is primitive of positive degree and irreducible in $R[x]$, it is irreducible in $K[x]$ by (ii), hence prime there ($K[x]$ is a PID). If $f\mid gh$

in $R[x]$, then f divides g, say, in $K[x]$: $g = fk$ with $k = ck_1$, k_1 primitive; by (i) fk_1 is primitive, so c equals $c(g)$ up to a unit and lies in R; hence $k \in R[x]$ and $f \mid g$ in $R[x]$. These two kinds exhaust the irreducibles of $R[x]$: an irreducible of degree 0 is an irreducible element of R (a factorisation in R is one in $R[x]$, and $R[x]^\times = R^\times$), hence prime in R; an irreducible f of positive degree is primitive, since otherwise $f = c(f)f_1$ would be a factorisation into two non-units. So every irreducible is prime and uniqueness follows from Lemma 2.24(iii). The polynomial rings in several variables follow by induction, $R[x_1, \dots, x_n] = R[x_1, \dots, x_{n-1}][x_n]$. (iv) By (ii), $f = g_1 h_1$ in $\mathbb{Z}[x]$ with $g_1 = \lambda g$, $h_1 = \lambda' h$; comparing leading coefficients, $\lambda\lambda' = 1$ with $\lambda, \lambda' \in \mathbb{Z}$ the leading coefficients of g_1, h_1, so $\lambda = \pm 1$ and $g = \pm g_1 \in \mathbb{Z}[x]$. If $f(a/b) = 0$ then $\sum a_i a^i b^{n-i} = 0$, so $b \mid a_n a^n$ and $a \mid a_0 b^n$; since $\gcd(a, b) = 1$, Euclid's lemma gives $b \mid a_n$ and $a \mid a_0$. □

Theorem 2.33 (Eisenstein's criterion)**.** *Let R be a domain, P a prime ideal and $f = a_n x^n + \cdots + a_0 \in R[x]$, $n \geq 1$, with $a_n \notin P$, $a_i \in P$ for $i < n$, and $a_0 \notin P^2$. Then f is not a product of two polynomials of positive degree in $R[x]$. If R is a UFD with fraction field K and f is primitive, then f is irreducible in $R[x]$ and in $K[x]$. Examples: $x^n - p$; $x^2 + 3x + 3 = \Phi_3(x + 1)$; $\Phi_p(x + 1) = ((x + 1)^p - 1)/x$ and $\Phi_{p^k}(x + 1)$ (Theorem 2.58(vi)).*

Proof. Suppose $f = gh$ with $\deg g = r \geq 1$, $\deg h = s \geq 1$, $r + s = n$. Let k be the fraction field of the domain R/P and reduce modulo P: $\bar{g}\bar{h} = \bar{a}_n x^n$ in $k[x]$ with $\bar{a}_n \neq 0$. Then $\deg \bar{g} = r$ and $\deg \bar{h} = s$ (their degrees are at most r, s and add up to n). In the UFD $k[x]$ the prime x and units are the only factors of $\bar{a}_n x^n$, so $\bar{g} = bx^r$ and $\bar{h} = cx^s$. As $r, s \geq 1$, the constant terms $g(0)$, $h(0)$ lie in P, and $a_0 = g(0)h(0) \in P^2$, a contradiction. If R is a UFD and f is primitive, a factorisation $f = gh$ into non-units has both factors of positive degree (a constant non-unit factor would divide $c(f)$), so f is irreducible in $R[x]$, and in $K[x]$ by Theorem 2.32(ii). The examples: $x^n - p$ at $P = p\mathbb{Z}$; $\Phi_p(x + 1) = \sum_{i=1}^{p} \binom{p}{i} x^{i-1}$ has leading coefficient 1, the other coefficients divisible by p (Proposition 2.16(i)) and constant term $\binom{p}{1} = p$. □

For $p = 5$: $\Phi_5(x + 1) = \frac{(x+1)^5 - 1}{x} = x^4 + 5x^3 + 10x^2 + 10x + 5$, Eisenstein at 5. The condition $a_0 \notin P^2$ cannot be dropped: $x^2 - 4 = (x - 2)(x + 2)$ has all lower coefficients in $2\mathbb{Z}$ but $a_0 = -4 \in 4\mathbb{Z}$. The substitution $x \mapsto x + 1$ is often needed: Φ_5 itself has all coefficients equal to 1 and no prime divides them, and the shift replaces the roots ζ_5^a by the numbers $\zeta_5^a - 1$, which are all multiples of $\zeta_5 - 1$ in $\mathbb{Z}[\zeta_5]$, since $\zeta_5^a - 1 = (\zeta_5 - 1)(1 + \zeta_5 + \cdots + \zeta_5^{a-1})$; their product is $\Phi_5(1) = 5$ up to sign.

Proposition 2.34 (reduction modulo p)**.** *Let $f \in \mathbb{Z}[x]$ have degree n and let p be a prime not dividing the leading coefficient. If $f = gh$ in $\mathbb{Z}[x]$, then $\bar{f} = \bar{g}\bar{h}$ in $\mathbb{F}_p[x]$ with $\deg \bar{g} = \deg g$ and $\deg \bar{h} = \deg h$. Hence:*

(i) if f is primitive and $\bar{f}$ is irreducible in $\mathbb{F}_p[x]$, then f is irreducible in $\mathbb{Q}[x]$ (and in $\mathbb{Z}[x]$);

(ii) the degrees of the factors in any factorisation of f in $\mathbb{Q}[x]$ are sums of degrees of irreducible factors of $\bar{f}$ (disjoint sub-multisets); so if two primes give incompatible patterns, f is irreducible over $\mathbb{Q}$.

Proof. Reduction $\mathbb{Z}[x] \to \mathbb{F}_p[x]$ is a ring homomorphism. The leading coefficients of g and h multiply to that of f, which is nonzero modulo p, so neither leading coefficient vanishes modulo p. (i) A factorisation in $\mathbb{Q}[x]$ into factors of positive degree gives one in $\mathbb{Z}[x]$ with the same degrees (Theorem 2.32(ii)), and then one of $\bar{f}$ with the same degrees. (ii) Write $f = g_1 \cdots g_k$ in $\mathbb{Q}[x]$, hence (Gauss) in $\mathbb{Z}[x]$ with the same degrees; then $\bar{f} = \bar{g}_1 \cdots \bar{g}_k$, $\deg \bar{g}_i = \deg g_i$, and by unique factorisation in $\mathbb{F}_p[x]$ the irreducible factors of $\bar{f}$ are distributed among the $\bar{g}_i$. □

Warning 2.35 (x^4+1). The test works in one direction only. x^4+1 is irreducible over $\mathbb{Q}$: $(x+1)^4+1 = x^4+4x^3+6x^2+4x+2$ is Eisenstein at 2. But it is reducible modulo every prime p. For $p=2$, $x^4+1=(x+1)^4$. For odd p, $8 \mid p^2-1$, so the cyclic group $\mathbb{F}_{p^2}^\times$ (Theorem 2.47 and Proposition 2.46) contains an element ζ of order 8, and $\zeta^4=-1$. If x^4+1 were irreducible over $\mathbb{F}_p$, then $\mathbb{F}_p[x]/(x^4+1) \simeq \mathbb{F}_p[\zeta] \subseteq \mathbb{F}_{p^2}$ (Theorem 2.38(ii)) would have $p^4 \le p^2$ elements. (Checked with PARI for all $p<500$: every factor has degree at most 2.)

Example 2.36 (the 3-division polynomial of 11a1)**.** For $E =$ `11a1`: $y^2+y=x^3-x^2-10x-20$, the 3-division polynomial, whose roots are the x-coordinates of the points of order 3 (Chapter 9), is $\psi_3 = 3x^4-4x^3-60x^2-237x-21$. It is primitive, 5 does not divide its leading coefficient, and modulo 5 it is $3(x^4+2x^3+x+3)$, which is irreducible in $\mathbb{F}_5[x]$: the monic factor has no root (its values at $0,1,2,3,4$ are $3,2,2,1,1$), and it is not $(x^2+ax+b)(x^2+cx+d)$, since $bd=3$ leaves $(b,d) \in \{(1,3),(3,1),(2,4),(4,2)\}$, and in each case $a+c=2$, $ad+bc=1$ determine a,c and give $b+d+ac \in \{4,4,2,2\}$, never 0. By Proposition 2.34(i), ψ_3 is irreducible over $\mathbb{Q}$.

```
E = ellinit([0,-1,1,-10,-20]);      \\ 11a1
f = elldivpol(E, 3)                  \\ 3*x^4 - 4*x^3 - 60*x^2 - 237*x - 21
factormod(f, 5)                      \\ a single factor x^4 + 2*x^3 + x + 3
polisirreducible(f)                  \\ 1
```

In the paper 2.37. Proposition prop:ns ends: "The 3-division polynomial of E then factors as a product of two irreducible quadratics, and otherwise it is irreducible", and Section sec:anomaly checks that the 3-division polynomial of every violating curve (all of image 3Ns) factors as two quadratics. Proposition 2.34 is how such a statement is tested for a given curve: one prime p with $\bar{\psi}_3$ irreducible proves irreducibility, as for 11a1, whose mod 3 image is $\mathrm{GL}_2(\mathbb{F}_3)$. The converse direction (that a factorisation over $\mathbb{Q}$ is detected) needs the factorisation over $\mathbb{Q}$ itself, which PARI computes; the Galois-theoretic meaning of the pattern is Chapter 5.

Theorem 2.38 (Kronecker's construction)**.** *Let F be a field and $f \in F[x]$ irreducible of degree d.*

(i) $F[x]/(f)$ is a field containing (a copy of) F, of dimension d over F with basis $1, \bar{x}, \dots, \bar{x}^{d-1}$, and $f(\bar{x})=0$.

(ii) If α is a root of f in a field $K \supseteq F$, then $x \mapsto \alpha$ induces an isomorphism $F[x]/(f) \simeq F[\alpha]$; in particular $F[\alpha]$ is a field of dimension d over F.

(iii) For every nonconstant $g \in F[x]$ there is a field $K \supseteq F$, of finite dimension over F, in which g is a product of linear factors.

Proof. (i) (f) is maximal (Proposition 2.30(ii)), so the quotient is a field. $F \to F[x]/(f)$ is injective, as a nonzero constant is not divisible by f. Division by f (made monic) shows that $1, \bar{x}, \dots, \bar{x}^{d-1}$ span, and they are independent because a nonzero polynomial of degree $< d$ is not divisible by f. Clearly $f(\bar{x}) = \overline{f(x)} = 0$. (ii) Evaluation $F[x] \to K$, $x \mapsto \alpha$, has image $F[\alpha]$ and a kernel containing f, not equal to $F[x]$; as (f) is maximal, the kernel is (f). Apply Theorem 2.12(i). (iii) Induction on $\deg g$. Let f be an irreducible factor of g and $K_1 = F[x]/(f)$, in which f, hence g, has a root α_1; then $g=(x-\alpha_1)g_1$ in $K_1[x]$ (Proposition 2.30(iii)). By induction g_1 splits in some $K \supseteq K_1$ with $\dim_{K_1} K$ finite, and $\dim_F K = \dim_{K_1} K \cdot \dim_F K_1$ (a basis of K over F is given by the products of bases). □

In (i) the inverse of a nonzero class is computed by Bezout's identity: if $g \notin (f)$ then $\gcd(f,g)=1$ (f is irreducible), so $uf+vg=1$ for some $u,v \in F[x]$, and $\bar v = \bar g^{-1}$. For $F=\mathbb{Q}$ and $f=x^2-2$ this gives the familiar formula: in $\mathbb{Q}[x]/(x^2-2) \simeq \mathbb{Q}(\sqrt{2})$, with $t=\bar x$,

$$(a+bt)(a-bt)=a^2-2b^2, \qquad \text{so} \qquad (a+bt)^{-1}=\frac{a-bt}{a^2-2b^2},$$

and $a^2-2b^2 \neq 0$ for rational $(a,b)\neq(0,0)$ precisely because x^2-2 has no rational root. The point of the construction is that it needs no ambient field such as $\mathbb{C}$: over $\mathbb{F}_p$, where there is no such field to start from, it is the only way to produce a root.

Example 2.39 ($\mathbb{F}_9$ and the paper's matrix J)**.** x^2+1 has no root in $\mathbb{F}_3$ (its values at $0,1,2$ are $1,2,2$), so it is irreducible and $\mathbb{F}_9 := \mathbb{F}_3[x]/(x^2+1) = \mathbb{F}_3[i]$, $i=\bar x$, is a field with 9 elements (by Theorem 2.47 every field with 9 elements is isomorphic to it). In the basis $1, i$ of $\mathbb{F}_9$ over $\mathbb{F}_3$, multiplication by $-i$ sends $1 \mapsto -i$ and $i \mapsto 1$, so its matrix is the paper's $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ of Proposition prop:ns: $J = m_{-i}$, as in the standard models of Chapter 1. Its characteristic polynomial X^2+1 is irreducible over $\mathbb{F}_3$, so J has no eigenvalue in $\mathbb{F}_3$ and the eigenvalues $\pm i$ in $\mathbb{F}_9$. This is why the character ψ of order 4 in Proposition prop:ns takes values in $\mathbb{F}_9^\times$ and why the paper writes $\bar\rho_{E,3} \otimes \mathbb{F}_9 \simeq \operatorname{Ind}\psi$ (over $\mathbb{F}_3$ itself $\bar\rho_{E,3}$ is irreducible). More generally $\mathbb{F}_q[x]/(x^2-c)$, c a non-square, is the field $\mathbb{F}_q[\sqrt{c}]$ with q^2 elements used in Chapter 1.

2.5 The ring $\mathbb{Z}/n\mathbb{Z}$, the Chinese remainder theorem, units and primitive roots

The groups $(\mathbb{Z}/n\mathbb{Z})^\times$ are where Dirichlet characters live (Section 2.10), and the groups $(\mathbb{Z}/\ell^k\mathbb{Z})^\times = \mathbb{Z}_\ell^\times/(1+\ell^k\mathbb{Z}_\ell)$ ($k \geq 1$) are the finite levels of $\mathbb{Z}_\ell^\times$, the image of the cyclotomic character. The paper uses one fact about them in an essential way: in Lemma lem:h0, an isomorphism $\rho \bmod \ell^k \simeq (\rho \otimes \chi_\ell) \bmod \ell^k$ forces $\chi_\ell^2 \equiv 1 \pmod{\ell^k}$, and this is possible for $k \geq 1$ only when $\ell^k = 3$ (Corollary 2.44). The lifting-the-exponent lemma computes valuations such as $v_\ell(q^2-1)$ in the table of Section 1.

Proposition 2.40. *Let $n \geq 1$.*

(i) $a \bmod n$ is a unit of $\mathbb{Z}/n\mathbb{Z}$ iff $\gcd(a,n)=1$. For $n \geq 2$, $\mathbb{Z}/n\mathbb{Z}$ is a field iff it is a domain iff n is prime; we write $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$.

(ii) $\#(\mathbb{Z}/n\mathbb{Z})^\times = \varphi(n)$, the number of $1 \leq a \leq n$ prime to n, and $a^{\varphi(n)} \equiv 1 \pmod n$ for $\gcd(a,n)=1$ (Euler). Moreover $\varphi(p^k) = p^{k-1}(p-1)$ and $\sum_{d\mid n}\varphi(d) = n$.

(iii) The map $a \mapsto (x \mapsto ax)$ is an isomorphism $(\mathbb{Z}/n\mathbb{Z})^\times \simeq \operatorname{Aut}(\mathbb{Z}/n\mathbb{Z})$ (automorphisms of the additive group).

For $k \geq 2$, $\mathbb{Z}/p^k\mathbb{Z}$ is not a field (p is nilpotent in it), and in particular it is not $\mathbb{F}_{p^k}$.

Proof. (i) If $\gcd(a,n)=1$, Bezout gives $ua+vn=1$, so $ua \equiv 1$. If $d=\gcd(a,n)>1$ then $a\cdot(n/d) \equiv 0$ with $n/d \not\equiv 0$, so a is a zero divisor and not a unit. If $n=p$ is prime, every nonzero class is a unit; if $n=ab$ with $1<a,b<n$, then $\bar a\bar b = 0$ and $\mathbb{Z}/n$ is not a domain. A field is a domain. (ii) The first claim is (i); Euler's congruence is Lagrange's theorem in the group $(\mathbb{Z}/n)^\times$ (Chapter 1). Among $1,\dots,p^k$ exactly the p^{k-1} multiples of p are not prime to p^k. For

the sum, $\mathbb{Z}/n$ is cyclic of order n and has, for each $d \mid n$, exactly $\varphi(d)$ elements of order d (the generators of its unique subgroup of order d, Chapter 1); count the elements by their order. (iii) An endomorphism of the cyclic group $\mathbb{Z}/n$ is determined by the image a of 1, and it is $x \mapsto ax$; it is bijective iff a generates, iff $\gcd(a, n) = 1$. Composition corresponds to multiplication. □

For $n = 12$: $(\mathbb{Z}/12\mathbb{Z})^\times = \{1, 5, 7, 11\}$, so $\varphi(12) = 4$, and each of these units squares to 1 ($25 = 2 \cdot 12 + 1$, $49 = 4 \cdot 12 + 1$, $121 = 10 \cdot 12 + 1$), so $(\mathbb{Z}/12\mathbb{Z})^\times$ is not cyclic. The divisors $1, 2, 3, 4, 6, 12$ of 12 have $\varphi = 1, 1, 2, 2, 2, 4$, with sum 12. The class 2 is a zero divisor, as in the proof of (i): $2 \cdot 6 \equiv 0$.

Theorem 2.41 (Chinese remainder theorem)**.** *For $m, n \geq 1$ the reduction map $\mathbb{Z}/mn\mathbb{Z} \to \mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z}$ is a ring isomorphism iff $\gcd(m, n) = 1$. Hence for $n = \prod_i p_i^{k_i}$ the reduction maps give ring isomorphisms*

$$\mathbb{Z}/n\mathbb{Z} \simeq \prod_i \mathbb{Z}/p_i^{k_i}\mathbb{Z}, \qquad (\mathbb{Z}/n\mathbb{Z})^\times \simeq \prod_i (\mathbb{Z}/p_i^{k_i}\mathbb{Z})^\times,$$

and $\varphi(mn) = \varphi(m)\varphi(n)$ for coprime m, n, so $\varphi(n) = \prod_i p_i^{k_i - 1}(p_i - 1)$.

Proof. If $\gcd(m, n) = 1$ then $m\mathbb{Z} + n\mathbb{Z} = \mathbb{Z}$ and $m\mathbb{Z} \cdot n\mathbb{Z} = mn\mathbb{Z}$ (Proposition 2.11(iii)), and Proposition 2.13(ii) applies; (iii) of that proposition gives the decomposition over the prime powers $p_i^{k_i}$, which are pairwise coprime. If $d = \gcd(m, n) > 1$, every element of $\mathbb{Z}/m \times \mathbb{Z}/n$ has additive order dividing $\operatorname{lcm}(m, n) = mn/d < mn$, while $1 \in \mathbb{Z}/mn$ has order mn. The unit group of a product of rings is the product of the unit groups. (The group-theoretic version is in Chapter 1.) □

The inverse of the reduction map is explicit once Bezout's identity $um + vn = 1$ is known: the pair ($y \bmod m, z \bmod n$) comes from $x = y \cdot vn + z \cdot um$, since $vn \equiv 1 \pmod m$, $vn \equiv 0 \pmod n$, and symmetrically for um. For $m = 3$, $n = 5$ this is the computation after Proposition 2.13. For $\gcd(m, n) > 1$ the failure is visible already for $m = n = 2$: $\mathbb{Z}/4\mathbb{Z}$ is cyclic of order 4, while every element of $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ has order at most 2. The unit statement gives, for example, $(\mathbb{Z}/15\mathbb{Z})^\times \simeq (\mathbb{Z}/3\mathbb{Z})^\times \times (\mathbb{Z}/5\mathbb{Z})^\times$, of order $2 \cdot 4 = 8 = \varphi(15)$.

Lemma 2.42 (lifting the exponent)**.** *(i) Let ℓ be an odd prime and $a, b \in \mathbb{Z}$ with $\ell \mid a - b$ and $\ell \nmid ab$. Then $v_\ell(a^n - b^n) = v_\ell(a - b) + v_\ell(n)$ for every $n \geq 1$.*

(ii) If a is odd and $n \geq 2$ is even, then $v_2(a^n - 1) = v_2(a - 1) + v_2(a + 1) + v_2(n) - 1$.

(iii) For ℓ odd and $j \geq 0$, $v_\ell((1 + \ell)^{\ell^j} - 1) = j + 1$; hence $1 + \ell$ has order ℓ^{k-1} in $(\mathbb{Z}/\ell^k\mathbb{Z})^\times$.

(iv) Let $q \neq \ell$ be primes, ℓ odd, and d the order of q modulo ℓ. Then $v_\ell(q^f - 1) = 0$ if $d \nmid f$, and $v_\ell(q^f - 1) = v_\ell(q^d - 1) + v_\ell(f/d)$ if $d \mid f$.

(v) $v_\ell(q^2 - 1) = v_\ell(q - 1) + v_\ell(q + 1)$, and for ℓ odd at most one of the two terms is positive.

Proof. (i) If $\ell \nmid n$: $a^n - b^n = (a - b)S$ with $S = \sum_{i=0}^{n-1} a^{n-1-i}b^i \equiv na^{n-1} \not\equiv 0 \pmod \ell$, as $a \equiv b$. If $n = \ell$: write $a = b + t$ with $\ell \mid t$. By the binomial theorem, $a^j = (b + t)^j = b^j + jtb^{j-1} + (\text{terms divisible by } t^2)$, so modulo t^2, $a^{\ell-1-i}b^i \equiv b^{\ell-1} + (\ell - 1 - i)tb^{\ell-2}$, and summing over i (with $\sum_{i=0}^{\ell-1}(\ell - 1 - i) = 0 + 1 + \cdots + (\ell - 1)$),

$$S = \sum_{i=0}^{\ell-1} a^{\ell-1-i}b^i \equiv \ell b^{\ell-1} + tb^{\ell-2}\sum_{i=0}^{\ell-1}(\ell - 1 - i) = \ell b^{\ell-1} + tb^{\ell-2}\frac{\ell(\ell-1)}{2} \pmod{t^2}.$$

Since ℓ is odd, $\ell \mid \frac{\ell(\ell-1)}{2}$, so the second term and t^2 are divisible by ℓ^2, and $S \equiv \ell b^{\ell-1} \pmod{\ell^2}$: $v_\ell(S) = 1$. For general $n = \ell^s m$, $\ell \nmid m$, apply the first case to a, b and m: $v_\ell(a^m - b^m) = v_\ell(a-b)$. Then apply the second case s times, to the pairs $a^{m\ell^j}$, $b^{m\ell^j}$ for $j = 0, \dots, s-1$. These still satisfy the hypotheses: $a^{m\ell^j} \equiv b^{m\ell^j} \pmod{\ell}$ because $a \equiv b$, and neither is divisible by ℓ because $\ell \nmid ab$. Each application adds exactly 1 to the valuation, since $a^{m\ell^{j+1}} - b^{m\ell^{j+1}} = (a^{m\ell^j})^\ell - (b^{m\ell^j})^\ell$; so $v_\ell(a^n - b^n) = v_\ell(a-b) + s$. (ii) Write $n = 2^s m$ with m odd and $s \geq 1$. As in (i), $a^m - 1 = (a-1)(a^{m-1} + \cdots + 1)$ and $a^m + 1 = (a+1)(a^{m-1} - a^{m-2} + \cdots + 1)$, the second factors being sums of m odd terms, hence odd; so $v_2(a^m - 1) = v_2(a-1)$, $v_2(a^m+1) = v_2(a+1)$, and $v_2(a^{2m} - 1) = v_2((a^m-1)(a^m+1)) = v_2(a-1) + v_2(a+1)$. For odd x, $x^2 \equiv 1 \pmod 8$ (as $x^2 - 1 = (x-1)(x+1)$ is a product of two consecutive even numbers, one divisible by 4), so $x^2 + 1 \equiv 2 \pmod 8$ and $v_2(x^2+1) = 1$. For $j \geq 2$ put $x = a^{2^{j-2}m}$, which is odd; then $a^{2^j m} - 1 = (x^2-1)(x^2+1)$, so each further squaring adds exactly 1: $v_2(a^{2^j m} - 1) = v_2(a^{2^{j-1}m} - 1) + 1$. After the $s-1$ squarings from $2m$ to $2^s m = n$ the valuation is $v_2(a-1) + v_2(a+1) + (s-1)$. (iii) Apply (i) with $a = 1+\ell$, $b = 1$: $v_\ell((1+\ell)^{\ell^j} - 1) = 1 + j$. So $(1+\ell)^{\ell^{k-1}} \equiv 1 \pmod{\ell^k}$ but $(1+\ell)^{\ell^{k-2}} \not\equiv 1 \pmod{\ell^k}$ for $k \geq 2$; as the order divides ℓ^{k-1}, it equals ℓ^{k-1}. (iv) $\ell \mid q^f - 1$ iff $q^f \equiv 1 \pmod{\ell}$ iff $d \mid f$. If $d \mid f$, apply (i) to $a = q^d$, $b = 1$, $n = f/d$. (v) $q^2 - 1 = (q-1)(q+1)$, and an odd prime cannot divide both $q-1$ and $q+1$, whose difference is 2. □

Two checks. With $\ell = 3$, $a = 4$, $b = 1$, $n = 9$: (i) predicts $v_3(4^9 - 1) = v_3(3) + v_3(9) = 3$, and indeed $4^9 - 1 = 262143 = 3^3 \cdot 7 \cdot 19 \cdot 73$. At $\ell = 2$ the naive formula fails, which is why (ii) has the extra term: $v_2(3^2 - 1) = v_2(8) = 3$, not $v_2(3-1) + v_2(2) = 2$; (ii) gives $1 + 2 + 1 - 1 = 3$, and for $n = 4$ it gives $v_2(3^4 - 1) = v_2(80) = 1 + 2 + 2 - 1 = 4$. The failure comes from the step $n = \ell$ of the proof: for $\ell = 2$ the number $\frac{\ell(\ell-1)}{2} = 1$ is not divisible by ℓ.

Theorem 2.43 (primitive roots). *(i)* $(\mathbb{Z}/p\mathbb{Z})^\times = \mathbb{F}_p^\times$ *is cyclic of order* $p-1$*; a generator is a* primitive root *modulo* p.

(ii) For p *odd and* $k \geq 1$, $(\mathbb{Z}/p^k\mathbb{Z})^\times$ *is cyclic of order* $p^{k-1}(p-1)$. *More precisely, if* g *is a primitive root modulo* p *with* $g^{p-1} \not\equiv 1 \pmod{p^2}$ *(true for* g *or for* $g+p$*), then* g *generates* $(\mathbb{Z}/p^k\mathbb{Z})^\times$ *for every* k.

(iii) $(\mathbb{Z}/2\mathbb{Z})^\times$ *and* $(\mathbb{Z}/4\mathbb{Z})^\times$ *are cyclic. For* $k \geq 3$, $(\mathbb{Z}/2^k\mathbb{Z})^\times = \{\pm 1\} \times \langle 5 \rangle \simeq \mathbb{Z}/2 \times \mathbb{Z}/2^{k-2}$, *which is not cyclic.*

(iv) $(\mathbb{Z}/n\mathbb{Z})^\times$ *is cyclic iff* $n \in \{1, 2, 4, p^k, 2p^k\}$ *with* p *an odd prime and* $k \geq 1$.

Proof. (i) A finite subgroup of the multiplicative group of a field is cyclic (Chapter 1; the proof uses Proposition 2.30(iv)). (ii) Let g be a primitive root modulo p. If $g^{p-1} \equiv 1 \pmod{p^2}$, then $(g+p)^{p-1} \equiv g^{p-1} + (p-1)pg^{p-2} \equiv 1 - pg^{p-2} \not\equiv 1 \pmod{p^2}$, and $g+p$ is also a primitive root modulo p. So assume $g^{p-1} = 1 + pt$ with $p \nmid t$. The order o of g modulo p^k is a multiple of $p-1$ (its order modulo p) and divides $\varphi(p^k) = p^{k-1}(p-1)$, so $o = (p-1)p^j$ with $j \leq k-1$. By Lemma 2.42(i), $v_p(g^{(p-1)p^j} - 1) = v_p(g^{p-1} - 1) + j = 1 + j$, which is $\geq k$ only if $j \geq k-1$. So $o = \varphi(p^k)$. (iii) $(\mathbb{Z}/2)^\times = \{1\}$ and $(\mathbb{Z}/4)^\times = \{\pm 1\}$. Let $k \geq 3$. By Lemma 2.42(ii), $v_2(5^{2^j} - 1) = 2 + 1 + j - 1 = j + 2$ for $j \geq 1$, and $v_2(5 - 1) = 2$; so $5^{2^j} \equiv 1 \pmod{2^k}$ iff $j \geq k-2$, and 5 has order 2^{k-2}. All powers of 5 are $\equiv 1 \pmod 4$, so $-1 \notin \langle 5 \rangle$; the subgroup $\{\pm 1\} \times \langle 5 \rangle$ has $2^{k-1} = \varphi(2^k)$ elements and is everything. It has the two distinct elements -1 and $5^{2^{k-3}}$ of order 2, while a cyclic group has at most one. (iv) By Theorem 2.41, $(\mathbb{Z}/n)^\times \simeq \prod_i (\mathbb{Z}/p_i^{k_i})^\times$. For odd p the factor has even order $p^{k-1}(p-1)$, and $(\mathbb{Z}/2^k)^\times$ has even order for $k \geq 2$. If two factors have even order, each

contains an element of order 2, and the product contains a subgroup $\mathbb{Z}/2 \times \mathbb{Z}/2$, impossible in a cyclic group; if $8 \mid n$, the factor $(\mathbb{Z}/2^k)^\times$ is not cyclic and neither is a group containing it. This excludes every n outside the list. Conversely, $(\mathbb{Z}/2p^k)^\times \simeq (\mathbb{Z}/2)^\times \times (\mathbb{Z}/p^k)^\times \simeq (\mathbb{Z}/p^k)^\times$, and the other cases are (ii), (iii). (Checked numerically for all $n < 200$.) □

The proviso in (ii) is real. The class of 7 is a primitive root modulo 5 (it is $\equiv 2$, of order 4), but $7^4 = 2401 = 96 \cdot 25 + 1 \equiv 1 \pmod{25}$, so 7 has order 4 modulo 25 and does not generate the group of order 20; the replacement $7 + 5 = 12$ has $12^4 \equiv 11 \pmod{25}$ and is a generator. On the other hand 2 is a primitive root modulo 3 with $2^2 = 4 \not\equiv 1 \pmod 9$, so 2 generates $(\mathbb{Z}/3^k\mathbb{Z})^\times$ for every k: its orders modulo 9 and 27 are 6 and 18. (Orders computed with PARI's `znorder`.)

Corollary 2.44. *Let ℓ be an odd prime and $k \geq 1$.*

(i) The solutions of $a^2 \equiv 1 \pmod{\ell^k}$ are $a \equiv \pm 1$.

(ii) $a^2 \equiv 1 \pmod{\ell^k}$ holds for every a prime to ℓ iff $\varphi(\ell^k) = 2$ iff $\ell^k = 3$.

(iii) If $\chi\colon G \to (\mathbb{Z}/\ell^k)^\times$ is a homomorphism from a group with $\chi(g)^2 = 1$ for all g, and either χ is surjective or its image contains the class of 2, then $\ell^k = 3$. Example: $2^2 = 4 \not\equiv 1 \pmod 9$, and $4 \not\equiv 1 \pmod \ell$ for $\ell \geq 5$.

Proof. (i) $(\mathbb{Z}/\ell^k)^\times$ is cyclic of even order (Theorem 2.43(ii)), so it has exactly $\gcd(2, \varphi(\ell^k)) = 2$ elements with $x^2 = 1$ (Chapter 1): 1 and -1, distinct as $\ell^k \geq 3$. (Directly: $\ell^k \mid (a-1)(a+1)$, and the odd prime ℓ cannot divide both factors, whose difference is 2, so ℓ^k divides one of them.) (ii) By (i), every unit squares to 1 iff there are only two units. And $\varphi(\ell^k) = \ell^{k-1}(\ell - 1) = 2$ iff $\ell = 3$, $k = 1$. (iii) Every element of the image squares to 1, so it is ± 1 by (i). If χ is surjective, $(\mathbb{Z}/\ell^k)^\times = \{\pm 1\}$ and $\ell^k = 3$ by (ii). If 2 is in the image, $2 \equiv \pm 1 \pmod{\ell^k}$, so $\ell^k \mid 3$. □

In the paper 2.45. Lemma lem:h0: an element of exact order ℓ^k of $H^0(\mathbb{Q}, \mathrm{ad}^0\, T(1) \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell)$ gives an isomorphism $\rho \bmod \ell^k \simeq (\rho \otimes \chi_\ell) \bmod \ell^k$, and comparing determinants, $\chi_\ell(g)^2 \equiv 1 \pmod{\ell^k}$ for all $g \in G_\mathbb{Q}$. The cyclotomic character maps $G_\mathbb{Q}$ onto $\mathbb{Z}_\ell^\times$ (Chapter 5), hence onto $(\mathbb{Z}/\ell^k)^\times$; so Corollary 2.44(iii) gives $\ell^k \in \{1, 3\}$: "Since $\chi_\ell(G_\mathbb{Q}) = \mathbb{Z}_\ell^\times$ contains 2, and $4 \not\equiv 1$ modulo ℓ for $\ell \geq 5$ and modulo 9, this forces $k = 0$ for $\ell \geq 5$ and $k \leq 1$ for $\ell = 3$." Hence $h_\ell(E) = 0$ for $\ell \geq 5$ and $h_3(E) \leq 1$. The case $\ell^k = 3$ is the identity $\bar\chi_3^{\mathrm{cyc}} = \chi_{-3}$, whose Dirichlet side is Proposition 2.78(iii).

2.6 Finite fields

In this section and the next $q = p^r$ is a prime power (Convention 2.2). Finite fields are the residue fields of everything in the book: $\mathbb{F}_q$ at a bad prime q of E, $\mathbb{F}_\ell$ and $\mathbb{F}_9$ as coefficient fields of $\bar\rho$, and $\mathbb{F}_{q^f}$ in the unramified extensions of Chapter 7. We prove existence and uniqueness, the Frobenius automorphism and the subfields, count irreducible polynomials, and determine the roots of unity in $\mathbb{F}_q$; the last item is the arithmetic input of Lemma lem:euler. That $\mathrm{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q)$ is cyclic generated by $x \mapsto x^q$ is proved in Chapter 5.

Proposition 2.46. *Let F be a finite field.*

(i) $\mathrm{char}\, F = p$ is a prime, F contains the image $\mathbb{F}_p$ of $\mathbb{Z}$, and $\#F = p^r$ with $r = \dim_{\mathbb{F}_p} F$.

(ii) $F^\times$ is cyclic of order $p^r - 1$.

(iii) *Every $a \in F$ satisfies $a^{p^r} = a$, and $x^{p^r} - x = \prod_{a \in F}(x - a)$ in $F[x]$.*

(iv) *$F = \mathbb{F}_p[\alpha]$ for every generator α of $F^\times$.*

Proof. (i) $\mathbb{Z} \to F$ is not injective, as F is finite, so $\operatorname{char} F$ is a prime p (Proposition 2.9); the image is $\mathbb{Z}/p = \mathbb{F}_p$, and F is a finite-dimensional $\mathbb{F}_p$-vector space. (ii) is the cyclicity of finite subgroups of $K^\times$ (Chapter 1). (iii) For $a \neq 0$, Lagrange gives $a^{p^r-1} = 1$; and $0^{p^r} = 0$. So the p^r distinct linear polynomials $x - a$ divide $x^{p^r} - x$; they are pairwise coprime, so their product, monic of degree p^r, divides it and equals it. (iv) $\mathbb{F}_p[\alpha]$ contains 0 and all powers of α. □

Theorem 2.47 (existence and uniqueness of finite fields)**.** *Let $q = p^r$.*

(i) *There is a field with q elements.*

(ii) *Any two fields with q elements are isomorphic. We write $\mathbb{F}_q$ for any of them.*

(iii) *$\mathbb{F}_q \simeq \mathbb{F}_p[x]/(f)$ for every irreducible $f \in \mathbb{F}_p[x]$ of degree r (such f exist by Proposition 2.49).*

(iv) *The isomorphism in (ii) is not unique when $r > 1$ (compose with powers of the Frobenius, Proposition 2.48); inside a fixed algebraic closure of $\mathbb{F}_p$ the subfield with q elements is unique (Chapter 5).*

Proof. (i) Let $K \supseteq \mathbb{F}_p$ be a field in which $x^q - x$ splits (Theorem 2.38(iii)). Its roots are q distinct elements, since $x^q - x$ is separable (Proposition 2.31(iii)). They form a subfield: they contain 0, 1; if $a^q = a$ and $b^q = b$ then $(a \pm b)^q = a^q \pm b^q = a \pm b$ (Proposition 2.16; for $p = 2$, $-b = b$; for odd p, $(-b)^q = -b^q$), $(ab)^q = ab$, and $(a^{-1})^q = a^{-1}$. (ii) Let K, K' have q elements. Write $K = \mathbb{F}_p[\alpha]$ (Proposition 2.46(iv)). The kernel of $\mathbb{F}_p[x] \to K$, $x \mapsto \alpha$, is a nonzero ($\mathbb{F}_p[x]$ is infinite) prime ideal, so it is (f) with f monic irreducible, and $K \simeq \mathbb{F}_p[x]/(f)$. Since $\alpha^q = \alpha$, $f \mid x^q - x$. In $K'[x]$, $x^q - x = \prod_{b \in K'}(x - b)$, so by unique factorisation in $K'[x]$ the divisor f is a product of some of these linear factors and has a root $\beta \in K'$. By Theorem 2.38(ii), $\mathbb{F}_p[\beta] \simeq \mathbb{F}_p[x]/(f) \simeq K$, so $\mathbb{F}_p[\beta]$ has q elements and equals K'. (iii) $\mathbb{F}_p[x]/(f)$ is a field with p^r elements (Theorem 2.38(i)); apply (ii). (iv) If $\sigma\colon K \to K'$ is an isomorphism, so is $\sigma \circ \operatorname{Frob}_p^s$ for every s, and these are distinct for $0 \leq s < r$ by Proposition 2.48(i). □

Proposition 2.48 (Frobenius and subfields)**.** *Let $q = p^r$.*

(i) *$\operatorname{Frob}_p\colon x \mapsto x^p$ is a field automorphism of $\mathbb{F}_q$, its fixed points are exactly $\mathbb{F}_p$, and it has order exactly r.*

(ii) *For $d \mid r$, $\{x \in \mathbb{F}_q : x^{p^d} = x\}$ is a subfield with p^d elements, and it is the only subfield with p^d elements. A subfield with p^e elements exists only if $e \mid r$.*

(iii) *The fixed field of Frob_p^s is the subfield with $p^{\gcd(s,r)}$ elements.*

The fact that every automorphism of $\mathbb{F}_q$ is a power of Frob_p, so that $\operatorname{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q)$ is cyclic of order n generated by $x \mapsto x^q$, is proved in Chapter 5.

Proof. (i) Frob_p is an injective endomorphism of the finite field $\mathbb{F}_q$, hence bijective (Proposition 2.16(ii)). Its fixed points are the roots of $x^p - x$, at most p of them (Proposition 2.30(iv)), and every element of $\mathbb{F}_p$ is one (Fermat). By Proposition 2.46(iii), $\operatorname{Frob}_p^r = \mathrm{id}$. If $\operatorname{Frob}_p^s = \mathrm{id}$ with $1 \leq s < r$, all p^r elements would be roots of $x^{p^s} - x$, of degree $p^s < p^r$. (ii) The set is the fixed set of the automorphism Frob_p^d, hence a subfield. As $d \mid r$, $p^d - 1$ divides $p^r - 1$ (write

$r = dt$ and $y = p^d$; then $y^t - 1 = (y-1)(y^{t-1} + \cdots + 1)$), and for the same reason $x^{p^d-1} - 1$ divides $x^{p^r-1} - 1$; multiplying by x, $x^{p^d} - x$ divides $x^{p^r} - x$; since $x^{p^r} - x$ splits into distinct linear factors over $\mathbb{F}_q$, so does its divisor $x^{p^d} - x$, which therefore has exactly p^d roots in $\mathbb{F}_q$. A subfield L with p^d elements satisfies $x^{p^d} = x$ on L (Proposition 2.46(iii)), so it lies in this set, and equals it by counting. If L has p^e elements, $\mathbb{F}_q$ is an L-vector space of some dimension t, and $p^r = p^{et}$. (iii) Let $g = \gcd(s, r) = as + br$ with $a, b \in \mathbb{Z}$. In the cyclic group generated by Frob_p (of order r), $\mathrm{Frob}_p^g = (\mathrm{Frob}_p^s)^a$, since $\mathrm{Frob}_p^{br} = \mathrm{id}$. So an element fixed by Frob_p^s is fixed by Frob_p^g; the converse holds as $g \mid s$. Apply (ii) to $g \mid r$. □

Proposition 2.49. *Let q be a prime power and $r \geq 1$. In $\mathbb{F}_q[x]$,*

$$x^{q^r} - x = \prod_{d \mid r} \prod_{f \text{ monic irreducible, } \deg f = d} f,$$

each factor occurring once. Hence $q^r = \sum_{d \mid r} d N_d$, where N_d is the number of monic irreducible polynomials of degree d over $\mathbb{F}_q$, and

$$N_r = \frac{1}{r} \sum_{d \mid r} \mu(d)\, q^{r/d} > 0.$$

Over $\mathbb{F}_2$, $N_1, \ldots, N_8 = 2, 1, 2, 3, 6, 9, 18, 30$; over $\mathbb{F}_3$, $N_1, \ldots, N_5 = 3, 3, 8, 18, 48$, and the three monic irreducible quadratics are $x^2 + 1$, $x^2 + x + 2$, $x^2 + 2x + 2$.

Proof. The polynomial $x^{q^r} - x$ is separable, so no irreducible factor occurs twice ($f^2 \mid g$ implies $f \mid g'$). Let f be monic irreducible of degree d, $K = \mathbb{F}_q[x]/(f)$, a field with q^d elements, and $\alpha = \bar{x}$; f is the minimal polynomial of α, so $f \mid x^{q^r} - x$ iff $\alpha^{q^r} = \alpha$. The map $\phi\colon y \mapsto y^q$ is an automorphism of K fixing $\mathbb{F}_q$ (Proposition 2.46(iii) for $\mathbb{F}_q$), and it has order exactly d by the argument of Proposition 2.48(i). If $\alpha^{q^r} = \alpha$, then ϕ^r fixes $\mathbb{F}_q$ and α, hence all of $K = \mathbb{F}_q[\alpha]$, so $d \mid r$. If $d \mid r$, then $\alpha^{q^d} = \alpha$ and so $\alpha^{q^r} = \alpha$ (apply $y \mapsto y^{q^d}$ repeatedly, r/d times). Comparing degrees gives $q^r = \sum_{d \mid r} d N_d$. For Moebius inversion recall $\sum_{e \mid m} \mu(e) = 0$ for $m > 1$: if $p_1, \ldots, p_s$ ($s \geq 1$) are the distinct primes dividing m, only squarefree e contribute, and the sum is $\sum_{T \subseteq \{1,\ldots,s\}} (-1)^{\#T} = (1-1)^s = 0$. Hence

$$\sum_{d \mid r} \mu(d) q^{r/d} = \sum_{d \mid r} \mu(d) \sum_{e \mid r/d} e N_e = \sum_{e \mid r} e N_e \sum_{d \mid r/e} \mu(d) = r N_r,$$

since the inner sum is 1 for $e = r$ and 0 otherwise. For $r \geq 2$ the term $d = 1$ is q^r, and the others have absolute value $q^{r/d}$ with $r/d \leq r/2$ distinct integers; so

$$r N_r \geq q^r - \sum_{j=0}^{\lfloor r/2 \rfloor} q^j > q^r - q^{\lfloor r/2 \rfloor + 1} \geq 0,$$

using $\sum_{j=0}^{M} q^j = (q^{M+1} - 1)/(q-1) < q^{M+1}$ for $q \geq 2$, and $\lfloor r/2 \rfloor + 1 \leq r$; and $N_1 = q$. The numerical values follow from the formula; for the quadratics over $\mathbb{F}_3$, each of the three listed has no root in $\mathbb{F}_3$ and $N_2 = (9-3)/2 = 3$. □

For $q = 2$, $r = 2$ the factorisation reads $x^4 - x = x(x+1)(x^2 + x + 1)$ in $\mathbb{F}_2[x]$: the two linear polynomials and the unique irreducible quadratic, and $4 = 1 \cdot 2 + 2 \cdot 1$. The formula for N_r is the finite-field analogue of the prime number theorem: $N_r = \frac{q^r}{r} + O(\frac{q^{r/2}}{r})$, so a random monic polynomial of degree r is irreducible with probability about $1/r$.

Proposition 2.50 (roots of unity in $\mathbb{F}_q$)**.** *Let $q = p^r$ and $n \geq 1$.*

(i) $\mu_n(\mathbb{F}_q)$ is cyclic of order $\gcd(n, q-1)$; it has n elements iff $n \mid q-1$.

(ii) If $p \nmid n$, the least $f \geq 1$ with $\#\mu_n(\mathbb{F}_{q^f}) = n$ is the order of q in $(\mathbb{Z}/n\mathbb{Z})^\times$.

(iii) In characteristic p, $x^{p^k m} - 1 = (x^m - 1)^{p^k}$; there are no roots of unity of order divisible by p.

(iv) Let q be odd. Then -1 is a square in $\mathbb{F}_q$ iff $q \equiv 1 \pmod 4$. If moreover $p \neq 3$, then -3 is a square in $\mathbb{F}_q$ iff $\mathbb{F}_q$ contains a primitive cube root of unity iff $q \equiv 1 \pmod 3$; indeed $(1+2\zeta)^2 = -3$ for a primitive cube root of unity ζ, and $\zeta = (-1+s)/2$ is one if $s^2 = -3$.

(v) Let σ be an element of order 3 of any group and m an integer prime to 3. Then $\sigma^m = \sigma$ if $m \equiv 1 \pmod 3$ and $\sigma^m = \sigma^{-1}$ if $m \equiv 2 \pmod 3$. Likewise if σ has order 4 (or 2) and m is odd, $\sigma^m = \sigma$ or σ^{-1} according as $m \equiv 1$ or $3 \pmod 4$. In particular this applies to $\mu_3(K)$ and $\mu_4(K)$ for any field K and to $\zeta \mapsto \zeta^q$; in the notation of Proposition 2.78, $\sigma^m = \sigma^{\chi_{-3}(m)}$, resp. $\sigma^m = \sigma^{\chi_{-4}(m)}$.

Proof. (i) $\mu_n(\mathbb{F}_q)$ is the kernel of $x \mapsto x^n$ on the cyclic group $\mathbb{F}_q^\times$ of order $q-1$, of order $\gcd(n, q-1)$ (Chapter 1). (ii) By (i), $\#\mu_n(\mathbb{F}_{q^f}) = n$ iff $n \mid q^f - 1$ iff $q^f \equiv 1 \pmod n$. (iii) $(x^m-1)^{p^k} = x^{p^k m} - 1$ by Proposition 2.16. If ζ has order $p^k m$ with $k \geq 1$, then $\eta = \zeta^m$ satisfies $\eta^{p^k} = 1$, so $(\eta - 1)^{p^k} = 0$ and $\eta = 1$, contradicting the order. (iv) An element y with $y^2 = -1$ has order 4 (as $-1 \neq 1$), and conversely if y has order 4 then y^2 has order 2, so $y^2 = -1$, the unique element of order 2 of the cyclic group $\mathbb{F}_q^\times$. Such y exists iff $4 \mid q-1$. Next, a primitive cube root of unity ζ satisfies $\zeta^2 + \zeta + 1 = 0$ (as $\zeta \neq 1$ and $x^3 - 1 = (x-1)(x^2+x+1)$), so $(1+2\zeta)^2 = 1 + 4(\zeta + \zeta^2) = -3$. Conversely if $s^2 = -3$ and $\zeta = (-1+s)/2$ (2 is invertible), then $4(\zeta^2 + \zeta + 1) = (1 - 2s + s^2) + (-2 + 2s) + 4 = s^2 + 3 = 0$, and $\zeta \neq 1$ because $1+1+1 = 3 \neq 0$ ($p \neq 3$); so ζ has order 3. By (i), such ζ exists iff $3 \mid q-1$. (v) σ^m depends only on m modulo the order of σ, and $\sigma^2 = \sigma^{-1}$, resp. $\sigma^3 = \sigma^{-1}$. The value $\chi_{-3}(m) \equiv m \pmod 3$, resp. $\chi_{-4}(m) \equiv m \pmod 4$, is Proposition 2.78(i). □

In the paper 2.51. In Lemma lem:IV the paper writes "$\rho(\mathrm{Frob}_q)\sigma\rho(\mathrm{Frob}_q)^{-1} = \sigma^q = \sigma^{\chi_{-3}(q)}$", for an element σ of order 3 generating the image of inertia, and in the proof of Lemma lem:euler: "Frobenius centralises σ if $q \equiv 1 \pmod 3$ and inverts it if $q \equiv 2$, for either choice of Frobenius, so it acts on the line by $\chi_{-3}(q)$"; for types III, III* the same with an element τ of order 4 and $\chi_{-4}(q)$. The Galois input (Frobenius acts on the tame quotient of inertia by $x \mapsto x^q$) is Chapters 6 and 7; the arithmetic input is Proposition 2.50(v): $\sigma^q = \sigma^{\pm 1}$ according to q modulo 3, and $\pm 1 = \chi_{-3}(q)$. Conjugation by Frobenius on the invariant line spanned by $\sigma - \sigma^{-1}$ (resp. by τ) is then multiplication by $\chi_{-3}(q)$ (resp. $\chi_{-4}(q)$), and it does not matter whether the arithmetic or the geometric Frobenius is used, since ± 1 is its own inverse.

2.7 Powers in $\mathbb{F}_q^\times$

This section is the arithmetic of Lemma lem:tamfactor (the Tamagawa factor at a multiplicative prime). There q is a prime, $u \in \mathbb{Z}_q^\times$ is the unit part of the Tate parameter, and the Tamagawa factor of $\mathrm{ad}^0 T$ exceeds $t_\ell(E,q) = v_\ell(n)$ by $\min(v_\ell(n), v_\ell(q-1), v_\ell(c))$, where c is the class of the reduction $\bar{u}$ in $\mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^{v_\ell(q-1)}}$. We prove that this group is cyclic of order $\ell^{v_\ell(q-1)}$, that $v_\ell(c)$

does not depend on the identification with $\mathbb{Z}/\ell^{v_\ell(q-1)}$, and that $v_\ell(c) \geq k$ iff $\bar{u}$ is an ℓ^k-th power. The statements hold for any prime power q; the group theory is that of cyclic groups (Chapter 1).

Theorem 2.52. *Let q be a prime power, $m \geq 1$ and $d = \gcd(m, q-1)$.*

(i) The m-th power map of $\mathbb{F}_q^\times$ has kernel $\mu_d(\mathbb{F}_q)$, of order d, and image $(\mathbb{F}_q^\times)^m = (\mathbb{F}_q^\times)^d$, the unique subgroup of index d.

(ii) (Generalised Euler criterion.) $u \in \mathbb{F}_q^\times$ is an m-th power iff $u^{(q-1)/d} = 1$.

(iii) For a prime ℓ and $k \geq 0$,

$$\left[\mathbb{F}_q^\times : (\mathbb{F}_q^\times)^{\ell^k}\right] = \ell^{\min(k, v_\ell(q-1))}.$$

In particular, if $q \not\equiv 1 \pmod{\ell}$, the ℓ-th power map is bijective and every element is an ℓ^k-th power for every k; if $q \equiv 1 \pmod{\ell}$, exactly a fraction $1/\ell$ of the elements are ℓ-th powers.

(iv) ($m = 2$, q odd.) The squares form the subgroup of index 2, and $u^{(q-1)/2} = \pm 1$, with $+1$ iff u is a square.

Proof. $\mathbb{F}_q^\times$ is cyclic of order $q-1$ (Proposition 2.46). (i) and (iii) are the statements on cyclic groups of Chapter 1: for C cyclic of order N, $x \mapsto x^m$ has kernel $C[\gcd(m,N)]$ and image $C^{\gcd(m,N)}$ of index $\gcd(m,N)$; and $\gcd(\ell^k, q-1) = \ell^{\min(k, v_\ell(q-1))}$. (ii) The image C^d is the unique subgroup of order $(q-1)/d$, which is $C[(q-1)/d] = \{u : u^{(q-1)/d} = 1\}$. (iv) is (i), (ii) with $m = 2$, $d = 2$: $u^{(q-1)/2}$ squares to 1, so it is ± 1 (the roots of $x^2 - 1$). □

The hypothesis is $d = \gcd(m, q-1)$, not m: every element of $\mathbb{F}_{11}^\times$ is a cube, since $\gcd(3, 10) = 1$, although "$u^{10/3}$" is meaningless.

Proposition 2.53 (the class of a unit modulo ℓ-power powers)**.** *Let q be a prime power, $\ell \nmid q$ a prime, $v = v_\ell(q-1)$, and $A = \mathbb{F}_q^\times / (\mathbb{F}_q^\times)^{\ell^v}$.*

(i) A is cyclic of order ℓ^v. The projection restricted to $\mu_{\ell^v}(\mathbb{F}_q)$, the ℓ-primary part of $\mathbb{F}_q^\times$, is an isomorphism onto A, and $u \mapsto u^{(q-1)/\ell^v}$ induces an isomorphism $A \simeq \mu_{\ell^v}(\mathbb{F}_q)$.

(ii) A generator g of $\mathbb{F}_q^\times$ identifies A with $\mathbb{Z}/\ell^v$: $u = g^a \mapsto c(u) = a \bmod \ell^v$. Replacing g by another generator multiplies $c(u)$ by a unit of $\mathbb{Z}/\ell^v$; so $v_\ell(c(u))$, read as in Convention 2.3, does not depend on g.

(iii) For $0 \leq k \leq v$: $u \in (\mathbb{F}_q^\times)^{\ell^k}$ iff $v_\ell(c(u)) \geq k$. For $k \geq v$: $(\mathbb{F}_q^\times)^{\ell^k} = (\mathbb{F}_q^\times)^{\ell^v}$.

(iv) For $n \in \mathbb{Z} \setminus \{0\}$,

$$\min(v_\ell(n), v, v_\ell(c(u))) = \max\{k \leq \min(v_\ell(n), v) : u \in (\mathbb{F}_q^\times)^{\ell^k}\},$$

and this is ≥ 1 iff $\ell \mid n$, $q \equiv 1 \pmod{\ell}$ and u is an ℓ-th power in $\mathbb{F}_q^\times$.

(v) If q is prime and $u \in \mathbb{Z}_{(q)}^\times$ (or $u \in \mathbb{Z}_q^\times$, Chapter 7), the class of u means the class of its reduction $\bar{u} \in \mathbb{F}_q^\times$ (Proposition 2.21(iii)); we write $c(u) = c(\bar{u})$.

Proof. Write $C = \mathbb{F}_q^\times$, cyclic of order $q-1 = \ell^v m$ with $\ell \nmid m$. (i) $A = C/C^{\ell^v}$ has order $\gcd(\ell^v, q-1) = \ell^v$ and is cyclic, as a quotient of a cyclic group. C^{ℓ^v} is the unique subgroup of order m, i.e. $C[m]$, and $C = C[\ell^v] \times C[m]$ (Chapter 1), so $C[\ell^v] = \mu_{\ell^v}(\mathbb{F}_q)$ maps isomorphically onto $C/C[m] = A$. The map $u \mapsto u^m$ has kernel $C[m] = C^{\ell^v}$ and image $C^m = C[\ell^v]$. (ii) Every u is g^a with a well defined modulo $q-1$, hence modulo ℓ^v; the map $u \mapsto a \bmod \ell^v$ is a surjective homomorphism $C \to \mathbb{Z}/\ell^v$ whose kernel is $\{g^a : \ell^v \mid a\} = \langle g^{\ell^v}\rangle = C^{\ell^v}$. Another generator is $g' = g^b$ with $\gcd(b, q-1) = 1$; then $u = g'^{a'} = g^{ba'}$, so $c_g(u) = b\, c_{g'}(u)$ with b a unit modulo ℓ^v. Finally $\min(v_\ell(\tilde{b}\tilde{c}), v) = \min(v_\ell(\tilde{c}), v)$ when $\ell \nmid \tilde{b}$. (iii) For $k \le v$, $\gcd(\ell^k, q-1) = \ell^k$, so $C^{\ell^k} = \langle g^{\ell^k}\rangle = \{g^a : \ell^k \mid a\}$ (this condition on a is well defined modulo $q-1$), and $\ell^k \mid a$ iff $c(u) \in \ell^k\mathbb{Z}/\ell^v\mathbb{Z}$ iff $v_\ell(c(u)) \ge k$. For $k \ge v$, $C^{\ell^k} = C^{\gcd(\ell^k, q-1)} = C^{\ell^v}$. (iv) By (iii) the set of $k \in [0, v]$ with $u \in C^{\ell^k}$ is $\{0, 1, \dots, v_\ell(c(u))\}$, as $v_\ell(c(u)) \le v$. Intersecting with $k \le v_\ell(n)$, the maximum is $\min(v_\ell(n), v_\ell(c(u))) = \min(v_\ell(n), v, v_\ell(c(u)))$. It is ≥ 1 iff $v_\ell(n) \ge 1$, $v \ge 1$ and $v_\ell(c(u)) \ge 1$, the last meaning $u \in C^\ell$ by (iii). (v) is a definition, justified by Proposition 2.21(iii). □

When $v = 0$ the group A is trivial, $c(u) = 0 \in \mathbb{Z}/1$ and $v_\ell(c(u)) = 0$; the minimum in (iv) is then 0, as it should be. The identification $A \simeq \mathbb{F}_q^\times \otimes \mathbb{Z}_\ell \simeq \mathbb{Z}_\ell(1)/(q-1)$ used in the proof of Lemma lem:tamfactor is Chapters 3 and 17; the Kummer interpretation $\bar{u}^{(q-1)/\ell^k}$ = the value of a Kummer character at Frobenius is Chapter 5.

Example 2.54. (a) $q = 7$, $\ell = 3$: $v = 1$; the cubes in $\mathbb{F}_7^\times$ are $\{1, 6\}$. So $\bar{u} = -1$ is a cube and $\bar{u} = 2$ is not. A multiplicative prime $q = 7$ with $3 \mid n_7$ and $u \equiv -1 \pmod 7$ therefore contributes $v_3(n_7) + 1$ to $v_3(\mathrm{Tam}_7(\mathrm{ad}^0 T))$ by Lemma lem:tamfactor. (b) $q = 19$, $\ell = 3$: $v = 2$, and 2 is a primitive root modulo 19. The cubes are $\{1, 7, 8, 11, 12, 18\}$ and the ninth powers $\{1, 18\}$. With $g = 2$: $c(2) = 1$, $c(8) = 3$, $c(-1) = c(2^9) = 9 \bmod 9 = 0$, so $v_3(c) = 0, 1, 2$ respectively: 2 is not a cube, 8 is a cube but not a ninth power, and -1 is a ninth power. (c) $q = 13$, $\ell = 3$: $v = 1$, $(q-1)/3 = 4$, and u is a cube iff $u^4 = 1$; the cubes are $\{1, 5, 8, 12\}$, the fourth roots of unity. (d) $q = 5$, $\ell = 3$: $v = 0$, every element is a cube. $q = 11$, $\ell = 5$: $v = 1$, the fifth powers are $\{\pm 1\}$. (All lists recomputed with PARI's `znprimroot` and `znlog`.)

In the paper 2.55. Lemma lem:tamfactor states: "$c(u)$ the class of the reduction of u in $\mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^v}$, $v = v_\ell(q-1)$, identified with an element of $\mathbb{Z}/\ell^v$ by the choice of a generator; $v_\ell(c(u))$ does not depend on that choice, $v_\ell(0)$ is read as v, and $v_\ell(c(u)) \ge k$ if and only if the reduction of u is an ℓ^k-th power in $\mathbb{F}_q^\times$, for $k \le v$." (The book writes c for $c(u)$.) This is Proposition 2.53(i) to (iii) and (v), with Convention 2.3. The "In particular" clause ("with equality unless $q \equiv 1 \pmod \ell$, $\ell \mid n$ and the reduction of u is an ℓ-th power") is (iv). Remark rem:ko(1) and Section sec:tam test exactly this condition on the tables; Example 2.54 shows the three cases at $q = 19$. Here q is prime, so $\mathbb{F}_q = \mathbb{Z}/q\mathbb{Z}$ and "the class of u" is computed as a discrete logarithm of u mod q to a primitive root.

2.8 Roots of unity and cyclotomic polynomials

Roots of unity appear in the paper as ζ_3 and i (the images of inertia of types II to IV* have eigenvalues in μ_3, μ_4, μ_6), as μ_{ℓ^k} (the cyclotomic character, the Tate module $\mathbb{Z}_\ell(1)$), and through the condition $q \equiv 1 \pmod \ell$ of Lemma lem:tamfactor, which says that $\mathbb{F}_q$ contains the ℓ-th roots of unity. This section proves what is needed about cyclotomic polynomials over $\mathbb{Z}$ and modulo p; the irreducibility of all Φ_n and $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \simeq (\mathbb{Z}/n)^\times$ are Chapter 5.

Definition 2.56. For a field K, $\mu_n(K) = \{x \in K : x^n = 1\}$ and $\mu(K) = \bigcup_{n\geq 1} \mu_n(K)$, the group of roots of unity of K. A *primitive n-th root of unity* is an element of order exactly n in $K^\times$.

Proposition 2.57. *(i) $\mu_n(K)$ is cyclic of order dividing n; it has order n iff K contains a primitive n-th root of unity, and this requires* $\operatorname{char} K \nmid n$.

(ii) $\mu_n(\mathbb{C}) = \langle \zeta_n \rangle$; its primitive elements are the ζ_n^a with $\gcd(a,n) = 1$, $\varphi(n)$ in number.

(iii) $\mu(\mathbb{Q}) = \mu(\mathbb{R}) = \{\pm 1\}$, $\mu(\mathbb{Q}(i)) = \mu_4$ and $\mu(\mathbb{Q}(\zeta_3)) = \mu_6$.

Proof. (i) $\mu_n(K)$ is a finite subgroup of $K^\times$ ($x^n - 1$ has at most n roots), hence cyclic (Chapter 1), and its elements have order dividing n; a cyclic group of order dividing n has order n iff it has an element of order n. If $\operatorname{char} K = p \mid n$, then $x^n - 1 = (x^{n/p} - 1)^p$ and $\mu_n(K) = \mu_{n/p}(K)$ has order at most n/p. (ii) The roots of $x^n - 1$ in $\mathbb{C}$ are the n numbers $e^{2\pi i a/n} = \zeta_n^a$, $0 \leq a < n$; the order of ζ_n^a is $n/\gcd(a,n)$. (iii) A real root of unity has absolute value 1, so it is ± 1. Let K be $\mathbb{Q}(i)$ or $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$, a two-dimensional $\mathbb{Q}$-vector space, and $z \in \mu(K)$ of order m. The elements $1, z, z^2$ are linearly dependent over $\mathbb{Q}$, so the minimal polynomial h of z over $\mathbb{Q}$ (the monic generator of the kernel of $\mathbb{Q}[x] \to \mathbb{C}$, $x \mapsto z$) has degree at most 2, and it divides $x^m - 1$. By Theorem 2.32(iv), $h \in \mathbb{Z}[x]$. If $\deg h = 2$, $h = x^2 + bx + c$ with roots z and $\bar{z}$ (both roots of $x^m - 1$, of absolute value 1): $|c| = |z\bar{z}| = 1$ and $|b| = |z + \bar{z}| \leq 2$. If $c = -1$ the roots are real, hence ± 1, and $h = x^2 - 1$ is not irreducible; if $c = 1$, $b = \pm 2$ gives $(x \pm 1)^2$, not irreducible. So h is $x \mp 1$, $x^2 + 1$ or $x^2 \pm x + 1$, and $m \in \{1, 2, 4, 3, 6\}$. Now $\mathbb{Q}(i)$ does not contain ζ_3: if $(a + bi)^2 = -3$ with $a, b \in \mathbb{Q}$ then $ab = 0$, $a^2 - b^2 = -3$, so $a = 0$ and $b^2 = 3$, impossible. And $\mathbb{Q}(\sqrt{-3})$ does not contain i: $(a + b\sqrt{-3})^2 = -1$ forces $a = 0$, $3b^2 = 1$. Hence $\mu(\mathbb{Q}(i)) = \mu_4$ and $\mu(\mathbb{Q}(\zeta_3)) = \{\pm\zeta_3^j\} = \mu_6$. □

Theorem 2.58 (cyclotomic polynomials)**.** *For $n \geq 1$ let $\Phi_n(x) = \prod_{1\leq a\leq n,\ \gcd(a,n)=1} (x - \zeta_n^a) \in \mathbb{C}[x]$.*

(i) $x^n - 1 = \prod_{d\mid n} \Phi_d(x)$.

(ii) $\Phi_n \in \mathbb{Z}[x]$, monic of degree $\varphi(n)$.

(iii) $\Phi_n(x) = \prod_{d\mid n} (x^d - 1)^{\mu(n/d)}$, with μ the Moebius function.

(iv) $\Phi_p = x^{p-1} + \cdots + x + 1$; $\Phi_{p^k}(x) = \Phi_p(x^{p^{k-1}})$; $\Phi_{2m}(x) = \Phi_m(-x)$ for odd $m > 1$.

(v) $\Phi_1(1) = 0$; $\Phi_n(1) = p$ if $n = p^k$, $k \geq 1$; $\Phi_n(1) = 1$ if n has at least two distinct prime factors; $\Phi_n(0) = 1$ for $n \geq 2$.

(vi) Φ_{p^k} is irreducible over $\mathbb{Q}$.

Proof. (i) Group the n-th roots of unity by their order $d \mid n$; those of order d are the primitive d-th roots, the roots of Φ_d (Proposition 2.57(ii)). (ii) Induction on n: $\Phi_1 = x - 1$. By (i), $\Phi_n = (x^n - 1)/g$ with $g = \prod_{d\mid n, d<n} \Phi_d$ monic in $\mathbb{Z}[x]$ by induction. Division of $x^n - 1$ by the monic g in $\mathbb{Z}[x]$ (Proposition 2.30(i)) gives a quotient in $\mathbb{Z}[x]$ and a remainder, which must vanish by uniqueness of division in $\mathbb{C}[x]$. The degree is the number of primitive n-th roots of unity, $\varphi(n)$. (iii) In the field $\mathbb{C}(x)$, using (i), $\prod_{d\mid n} (x^d - 1)^{\mu(n/d)} = \prod_{d\mid n} \prod_{e\mid d} \Phi_e^{\mu(n/d)} = \prod_{e\mid n} \Phi_e^{\sum_{e\mid d\mid n} \mu(n/d)}$, and $\sum_{e\mid d\mid n} \mu(n/d) = \sum_{k\mid n/e} \mu(k)$ (put $k = n/d$, which runs over the divisors of n/e) is 1 if $e = n$ and 0 otherwise (the identity $\sum_{k\mid m} \mu(k) = 0$ for $m > 1$ is proved

in Proposition 2.49). For example $\Phi_6 = \frac{(x^6-1)(x-1)}{(x^3-1)(x^2-1)} = \frac{x^3+1}{x+1} = x^2 - x + 1$. (iv) By (iii), $\Phi_{p^k} = (x^{p^k}-1)/(x^{p^{k-1}}-1) = \Phi_p(x^{p^{k-1}})$, and $\Phi_p = (x^p-1)/(x-1)$. For odd $m > 1$ the divisors of $2m$ are the d and $2d$ with $d \mid m$, and $\mu(2m/d) = -\mu(m/d)$, $\mu(2m/2d) = \mu(m/d)$; so $\Phi_{2m} = \prod_{d|m}((x^{2d}-1)/(x^d-1))^{\mu(m/d)} = \prod_{d|m}(x^d+1)^{\mu(m/d)}$. On the other hand $\Phi_m(-x) = \prod_{d|m}(-(x^d+1))^{\mu(m/d)}$ (d is odd) $= (-1)^{\sum_{d|m}\mu(m/d)}\prod_{d|m}(x^d+1)^{\mu(m/d)}$, and the sign is $+1$ as $m > 1$. (v) $\Phi_1(1) = 0$ and $\Phi_{p^k}(1) = \Phi_p(1) = p$ by (iv). For $n > 1$, (i) gives $1 + x + \cdots + x^{n-1} = \prod_{d|n,\, d>1}\Phi_d(x)$, and at $x = 1$: $n = \prod_{d|n,d>1}\Phi_d(1)$. The prime power divisors $d = p^j > 1$ contribute $\prod_p p^{v_p(n)} = n$, so the product of $\Phi_d(1)$ over the divisors $d > 1$ that are not prime powers is 1; by induction on n all of them except $d = n$ are 1, hence so is $\Phi_n(1)$ when n is not a prime power. Similarly $x^n - 1$ at $x = 0$ gives $-1 = \Phi_1(0)\prod_{d|n,d>1}\Phi_d(0) = -\prod_{d|n,d>1}\Phi_d(0)$, and induction gives $\Phi_n(0) = 1$. (vi) Put $g(x) = \Phi_{p^k}(x+1)$, monic of degree $\varphi(p^k)$. Modulo p, $\Phi_{p^k} = (x^{p^k}-1)/(x^{p^{k-1}}-1) \equiv (x-1)^{p^k}/(x-1)^{p^{k-1}} = (x-1)^{\varphi(p^k)}$ (Proposition 2.16; division by a monic polynomial commutes with reduction), so $g \equiv x^{\varphi(p^k)} \pmod p$, and $g(0) = \Phi_{p^k}(1) = p$. By Eisenstein (Theorem 2.33) g is irreducible, and so is Φ_{p^k}, since $x \mapsto x+1$ is an automorphism of $\mathbb{Q}[x]$ preserving degrees. □

n	$\Phi_n(x)$	$\Phi_n(1)$	n	$\Phi_n(x)$	$\Phi_n(1)$
1	$x-1$	0	7	$x^6+x^5+x^4+x^3+x^2+x+1$	7
2	$x+1$	2	8	x^4+1	2
3	x^2+x+1	3	9	x^6+x^3+1	3
4	x^2+1	2	10	$x^4-x^3+x^2-x+1$	1
5	$x^4+x^3+x^2+x+1$	5	11	$x^{10}+x^9+\cdots+x+1$	11
6	x^2-x+1	1	12	x^4-x^2+1	1

Proposition 2.59. *Let p be a prime with $p \nmid n$, and write $\bar\Phi_n$ for the reduction of Φ_n modulo p.*

(i) $\bar\Phi_n$ divides $x^n - 1$ in $\mathbb{F}_p[x]$, so it is separable; in any field of characteristic p its roots are exactly the elements of order n.

(ii) For $a \in \mathbb{Z}$: $p \mid \Phi_n(a)$ iff $a \bmod p$ has order exactly n in $\mathbb{F}_p^\times$. Hence every prime divisor $p \nmid n$ of $\Phi_n(a)$ satisfies $p \equiv 1 \pmod n$.

(iii) There are infinitely many primes $p \equiv 1 \pmod n$.

(iv) $\bar\Phi_n$ is a product of distinct linear factors in $\mathbb{F}_p[x]$ iff $p \equiv 1 \pmod n$.

The complete factorisation pattern ($\varphi(n)/f$ irreducible factors of degree f, f the order of p modulo n) is Chapter 5.

Proof. (i) Reduce Theorem 2.58(i) modulo p: $x^n - 1 = \prod_{d|n}\bar\Phi_d$, and $x^n - 1$ is separable over $\mathbb{F}_p$ (Proposition 2.31(iii)). Let K have characteristic p; enlarging K (Theorem 2.38(iii)) we may assume $x^n - 1$ splits in K, which does not change orders of elements of K. The roots of $x^n - 1$ are the n elements of $\mu_n(K)$, those of order d being, by induction on n, the roots of $\bar\Phi_d$ for $d < n$; since the roots of the $\bar\Phi_d$ are pairwise distinct, the roots of $\bar\Phi_n$ are the remaining elements, of order exactly n. (ii) $p \mid \Phi_n(a)$ iff $\bar a$ is a root of $\bar\Phi_n$ in $\mathbb{F}_p$, iff $\bar a$ has order n in $\mathbb{F}_p^\times$ by (i) ($\bar a \neq 0$ because $\bar\Phi_n(0) = 1$ for $n \geq 2$; for $n = 1$ the claim is clear). Then $n \mid p - 1$. (iii) For $n = 1$ this is Euclid's theorem; let $n \geq 2$ and S a finite set of primes, $N = n\prod_{p\in S} p$. For an integer

t, $\Phi_n(tN) \equiv \Phi_n(0) = 1 \pmod N$, so $\Phi_n(tN)$ is prime to n and to every $p \in S$. For t large, $|\Phi_n(tN)| > 1$ (Φ_n is monic of positive degree), so it has a prime divisor $p \notin S$, $p \nmid n$, and $p \equiv 1 \pmod n$ by (ii). (iv) If $p \equiv 1 \pmod n$, the cyclic group $\mathbb{F}_p^\times$ contains $\varphi(n)$ elements of order n, all roots of $\bar\Phi_n$, which has degree $\varphi(n)$. Conversely a root in $\mathbb{F}_p$ has order n, so $n \mid p-1$. □

For example $\Phi_{12}(2) = 16 - 4 + 1 = 13 \equiv 1 \pmod{12}$ and $\Phi_9(2) = \Phi_3(8) = 73 \equiv 1 \pmod 9$; and 2 has order 12 modulo 13 and order 9 modulo 73. In the paper the primes $q \equiv 1 \pmod \ell$ of Lemma lem:tamfactor are exactly those with $\mu_\ell \subset \mathbb{F}_q$ (Proposition 2.50(i)).

2.9 Quadratic residues and quadratic reciprocity

The paper's quadratic characters are Kronecker symbols: $\chi_{-3} = \left(\frac{-3}{\cdot}\right)$, $\chi_{-4} = \left(\frac{-4}{\cdot}\right)$, and $\chi_{q^*} = \left(\frac{q^*}{\cdot}\right)$, the character of $\mathbb{Q}(\sqrt{q^*})$ by which Lemma lem:twist twists. That χ_{q^*} is "the quadratic character of conductor q", i.e. that $\left(\frac{q^*}{n}\right) = \left(\frac{n}{q}\right)$ for all n, is quadratic reciprocity (Proposition 2.69). We prove reciprocity by Gauss sums in characteristic p, extend it to Jacobi and Kronecker symbols, and show that $\left(\frac{D}{\cdot}\right)$ is a Dirichlet character modulo $|D|$ for every discriminant D. Chapter 6 gives a second proof and the meaning of $\chi_D(p)$ (D fundamental) as a splitting law.

Definition 2.60. For an odd prime p and $a \in \mathbb{Z}$ the *Legendre symbol* is $\left(\frac{a}{p}\right) = 0$ if $p \mid a$, 1 if a is a nonzero square modulo p (a *quadratic residue*), and -1 otherwise (a *non-residue*).

Proposition 2.61. *Let p be an odd prime.*

(i) (Euler's criterion) $\left(\frac{a}{p}\right) \equiv a^{(p-1)/2} \pmod p$.

(ii) $\left(\frac{ab}{p}\right) = \left(\frac{a}{p}\right)\left(\frac{b}{p}\right)$; *$a \mapsto \left(\frac{a}{p}\right)$ is the unique homomorphism of order 2 from $(\mathbb{Z}/p)^\times$ to $\{\pm 1\}$; there are $(p-1)/2$ residues and $(p-1)/2$ non-residues.*

(iii) $\left(\frac{-1}{p}\right) = (-1)^{(p-1)/2}$.

(iv) For $p = 3$: $\left(\frac{a}{3}\right) \equiv a \pmod 3$ *for all a.*

Proof. (i) For $p \mid a$ both sides are 0; otherwise it is Theorem 2.52(iv) with $q = p$. (ii) Multiplicativity follows from (i), as $1 \not\equiv -1 \pmod p$. A homomorphism onto $\{\pm 1\}$ has a kernel of index 2, and the cyclic group $(\mathbb{Z}/p)^\times$ has only one subgroup of index 2, the squares (Theorem 2.52(i)). (iii) is (i) for $a = -1$. (iv) The nonzero squares modulo 3 are $\{1\}$, so $\left(\frac{2}{3}\right) = -1 \equiv 2$. □

For $p = 7$ the squares of $1, \dots, 6$ are $1, 4, 2, 2, 4, 1$, so the residues are $\{1, 2, 4\}$ and the non-residues $\{3, 5, 6\}$. Euler's criterion agrees: $3^3 = 27 \equiv -1$ and $2^3 = 8 \equiv 1 \pmod 7$. In particular $\left(\frac{-1}{7}\right) = -1$, as (iii) says for $7 \equiv 3 \pmod 4$.

Proposition 2.62 (the quadratic Gauss sum)**.** *Let q be an odd prime, K a field of characteristic $\neq q$ containing a primitive q-th root of unity ζ, and $g = \sum_{a=1}^{q-1} \left(\frac{a}{q}\right)\zeta^a \in K$.*

(i) $g^2 = q^* = (-1)^{(q-1)/2} q$ in K; in particular $g \neq 0$.

(ii) For b prime to q, $\sum_{a=1}^{q-1} \left(\frac{a}{q}\right)\zeta^{ab} = \left(\frac{b}{q}\right) g$.

(iii) $\sqrt{q^*} \in \mathbb{Q}(\zeta_q)$: over $\mathbb{C}$ with $\zeta = \zeta_q$, $g \in \mathbb{Z}[\zeta_q]$ and $g^2 = q^*$.

Proof. For $b \in \mathbb{Z}$, $\sum_{a=0}^{q-1} \zeta^{ab}$ is q if $q \mid b$ and 0 otherwise: if $q \nmid b$, $\zeta^b \neq 1$ is a root of $x^q - 1 = (x-1)(1 + x + \cdots + x^{q-1})$, hence of the second factor. So $\sum_{a=1}^{q-1} \zeta^{ab}$ is $q-1$ if $q \mid b$ and -1 otherwise. Also $\sum_{c=1}^{q-1} \left(\frac{c}{q}\right) = 0$ by Proposition 2.61(ii). (ii) As a runs over $(\mathbb{Z}/q)^\times$ so does $c = ab$, and $\left(\frac{a}{q}\right) = \left(\frac{c}{q}\right)\left(\frac{b}{q}\right)$ since $\left(\frac{b}{q}\right)^{-1} = \left(\frac{b}{q}\right)$. (i) $g^2 = \sum_{a,b} \left(\frac{ab}{q}\right) \zeta^{a+b}$. Substitute $b = ac$ (c runs over $(\mathbb{Z}/q)^\times$ for fixed a): $\left(\frac{a \cdot ac}{q}\right) = \left(\frac{a^2}{q}\right)\left(\frac{c}{q}\right) = \left(\frac{c}{q}\right)$. The inner sum over a is $\sum_{a=1}^{q-1} \zeta^{a(1+c)}$, which by the first paragraph is $q-1$ for the one value $c \equiv -1$ and -1 for the others; then $\sum_{c \neq -1} \left(\frac{c}{q}\right) = 0 - \left(\frac{-1}{q}\right)$. So

$$g^2 = \sum_{c=1}^{q-1} \left(\frac{c}{q}\right) \sum_{a=1}^{q-1} \zeta^{a(1+c)} = \left(\frac{-1}{q}\right)(q-1) - \sum_{c \neq -1} \left(\frac{c}{q}\right) = \left(\frac{-1}{q}\right)(q-1) + \left(\frac{-1}{q}\right) = \left(\frac{-1}{q}\right) q,$$

which is q^* by Proposition 2.61(iii). It is nonzero because $\operatorname{char} K \neq q$. (iii) is (i) over $\mathbb{C}$. □

For $q = 3$ over $\mathbb{C}$: $g = \zeta_3 - \zeta_3^2 = 1 + 2\zeta_3 = \sqrt{-3}$, and $g^2 = -3 = 3^*$. For $q = 5$: $g = \zeta_5 - \zeta_5^2 - \zeta_5^3 + \zeta_5^4 = 2\cos\frac{2\pi}{5} - 2\cos\frac{4\pi}{5} = \sqrt{5}$ (Exercise 2.105). The point of allowing an arbitrary field K is the proof of reciprocity below, where K is a finite field of characteristic $p \neq q$ and the identity $g^2 = q^*$ is used inside K.

Remark 2.63 (the sign of the Gauss sum). Over $\mathbb{C}$ with $\zeta = \zeta_q$, Gauss proved $g = \sqrt{q}$ if $q \equiv 1 \pmod 4$ and $g = i\sqrt{q}$ if $q \equiv 3 \pmod 4$. We do not prove this and do not use it; see [87, Chapter 6, Section 6.4]. (Checked numerically for all $q < 60$.)

Theorem 2.64 (quadratic reciprocity)**.** *Let $p \neq q$ be odd primes.*

(i) $\left(\frac{p}{q}\right)\left(\frac{q}{p}\right) = (-1)^{\frac{p-1}{2}\cdot\frac{q-1}{2}}$*; equivalently* $\left(\frac{q^*}{p}\right) = \left(\frac{p}{q}\right)$.

(ii) (First supplement) $\left(\frac{-1}{p}\right) = (-1)^{(p-1)/2}$.

(iii) (Second supplement) $\left(\frac{2}{p}\right) = (-1)^{(p^2-1)/8}$*, that is, 2 is a square modulo p iff* $p \equiv \pm 1 \pmod 8$.

Proof. (i) Let f be the order of p modulo q. By Proposition 2.50(ii) (and Theorem 2.47) the field $K = \mathbb{F}_{p^f}$ contains a primitive q-th root of unity ζ; its characteristic p is different from q. Let $g = \sum_a \left(\frac{a}{q}\right)\zeta^a \in K$. By Proposition 2.62(i), $g^2 = q^*$, an element of $\mathbb{F}_p \subseteq K$. By Proposition 2.16, and because $\left(\frac{a}{q}\right)^p = \left(\frac{a}{q}\right)$ (p odd),

$$g^p = \sum_a \left(\frac{a}{q}\right)^p \zeta^{ap} = \sum_a \left(\frac{a}{q}\right)\zeta^{ap} = \left(\frac{p}{q}\right) g$$

by Proposition 2.62(ii). As $g \neq 0$, $g^{p-1} = \left(\frac{p}{q}\right)$. But $g^{p-1} = (g^2)^{(p-1)/2} = (q^*)^{(p-1)/2} = \left(\frac{q^*}{p}\right)$ in $\mathbb{F}_p$ by Euler's criterion. So $\left(\frac{q^*}{p}\right) = \left(\frac{p}{q}\right)$ in $\mathbb{F}_p$, hence as integers ($1 \neq -1$ in $\mathbb{F}_p$). Finally $\left(\frac{q^*}{p}\right) = \left(\frac{-1}{p}\right)^{(q-1)/2}\left(\frac{q}{p}\right) = (-1)^{\frac{p-1}{2}\frac{q-1}{2}}\left(\frac{q}{p}\right)$. (ii) is Proposition 2.61(iii). (iii) As p is odd, $8 \mid p^2 - 1$, so $\mathbb{F}_{p^2}$ contains an element ζ of order 8 (Proposition 2.50(i)). Then $\zeta^4 = -1$ and $\zeta^{-2} = \zeta^6 = -\zeta^2$. Put $\tau = \zeta + \zeta^{-1}$; then $\tau^2 = \zeta^2 + 2 + \zeta^{-2} = 2$, so $\tau \neq 0$. Now $\tau^p = \zeta^p + \zeta^{-p}$, which is τ if $p \equiv \pm 1 \pmod 8$, and if $p \equiv \pm 3 \pmod 8$ it is $\zeta^3 + \zeta^{-3} = \zeta^3 + \zeta^5 = \zeta^4(\zeta^{-1} + \zeta) = -\tau$. Hence $2^{(p-1)/2} = \tau^{p-1} = \pm 1$ accordingly, and Euler's criterion concludes. Note that $(-1)^{(p^2-1)/8}$ is 1 for $p \equiv \pm 1$ and -1 for $p \equiv \pm 3 \pmod 8$. □

Definition 2.65. For an odd integer $n = \prod_i p_i^{e_i} > 0$ and $a \in \mathbb{Z}$, the *Jacobi symbol* is $\left(\frac{a}{n}\right) = \prod_i \left(\frac{a}{p_i}\right)^{e_i}$ (Legendre symbols; $\left(\frac{a}{1}\right) = 1$).

Proposition 2.66. *Let $m, n > 0$ be odd.*

(i) $\left(\frac{a}{n}\right)$ *is multiplicative in a and in n, depends only on $a \bmod n$, and vanishes iff* $\gcd(a,n) > 1$.

(ii) (Reciprocity and supplements.) If $\gcd(m,n) = 1$, *then* $\left(\frac{m}{n}\right)\left(\frac{n}{m}\right) = (-1)^{\frac{m-1}{2}\cdot\frac{n-1}{2}}$. *Moreover* $\left(\frac{-1}{n}\right) = (-1)^{(n-1)/2}$ *and* $\left(\frac{2}{n}\right) = (-1)^{(n^2-1)/8}$.

(iii) $\left(\frac{a}{n}\right) = 1$ *does not imply that a is a square modulo n:* $\left(\frac{2}{15}\right) = \left(\frac{2}{3}\right)\left(\frac{2}{5}\right) = (-1)(-1) = 1$, *but 2 is not a square modulo 3, hence not modulo 15. (If* $\left(\frac{a}{n}\right) = -1$, *then a is not a square modulo n.)*

(iv) Reciprocity computes $\left(\frac{a}{n}\right)$ *without factoring n: reduce a modulo n, remove the factors -1 and 2 with (ii), and invert the remaining odd symbol. For instance, 1009 being prime,* $\left(\frac{713}{1009}\right) = \left(\frac{1009}{713}\right) = \left(\frac{296}{713}\right) = \left(\frac{2}{713}\right)^3\left(\frac{37}{713}\right) = \left(\frac{713}{37}\right) = \left(\frac{10}{37}\right) = \left(\frac{2}{37}\right)\left(\frac{5}{37}\right) = (-1)\left(\frac{37}{5}\right) = -\left(\frac{2}{5}\right) = 1$, *so 713 is a square modulo 1009 (PARI's* `kronecker(713,1009)` *returns 1).*

Proof. (i) is inherited from the Legendre symbol factor by factor. (ii) Let $e(n) = \frac{n-1}{2}$ and $w(n) = \frac{n^2-1}{8}$ modulo 2, for odd n. Both are additive: $mn-1 = (m-1)(n-1)+(m-1)+(n-1)$ with $4 \mid (m-1)(n-1)$, and $m^2n^2-1 = (m^2-1)(n^2-1)+(m^2-1)+(n^2-1)$ with $64 \mid (m^2-1)(n^2-1)$. Write $m = \prod p_i$, $n = \prod q_j$ (with repetitions). By Theorem 2.64, $\left(\frac{m}{n}\right)\left(\frac{n}{m}\right) = \prod_{i,j}\left(\frac{p_i}{q_j}\right)\left(\frac{q_j}{p_i}\right) = (-1)^{\sum_{i,j} e(p_i)e(q_j)} = (-1)^{e(m)e(n)}$, and likewise $\left(\frac{-1}{n}\right) = (-1)^{\sum_j e(q_j)} = (-1)^{e(n)}$, $\left(\frac{2}{n}\right) = (-1)^{\sum_j w(q_j)} = (-1)^{w(n)}$. (iii) A square modulo 15 is a square modulo 3. If $\left(\frac{a}{n}\right) = -1$, some $\left(\frac{a}{p_i}\right) = -1$. (iv) In the example $713 \equiv 1 \pmod 8$, $37 \equiv 5 \pmod 8$, and $713 \equiv 1$, $37 \equiv 1 \pmod 4$, so no signs arise from (ii) in the inversions. □

Definition 2.67. The *Kronecker symbol* $\left(\frac{a}{n}\right)$, for $a, n \in \mathbb{Z}$, extends the Jacobi symbol using Convention 2.4: for $n = s2^e\prod_i p_i^{e_i} \neq 0$ with a sign $s = \pm 1$ and odd primes p_i,

$$\left(\frac{a}{n}\right) = \left(\frac{a}{s}\right)\left(\frac{a}{2}\right)^e \prod_i \left(\frac{a}{p_i}\right)^{e_i},$$

and $\left(\frac{a}{0}\right) = 1$ if $a = \pm 1$, 0 otherwise. A *discriminant* is an integer $D \neq 0$ with $D \equiv 0$ or $1 \pmod 4$. A *fundamental discriminant* is a discriminant D with either $D \equiv 1 \pmod 4$ squarefree, or $D = 4m$ with $m \equiv 2, 3 \pmod 4$ squarefree. The *prime discriminants* are -4, 8, -8 and $q^* = (-1)^{(q-1)/2}q$ for odd primes q. For a fundamental discriminant D put $\chi_D(a) := \left(\frac{D}{a}\right)$ for all $a \in \mathbb{Z}$; for a discriminant that is not fundamental no name χ_D is introduced, and the function $\left(\frac{D}{\cdot}\right)$ is written as a Kronecker symbol (Convention 2.5).

The definition is made so that $n \mapsto \left(\frac{D}{n}\right)$, a function of the lower entry, is a character; for the Jacobi symbol it is the upper entry that varies. For $D = -3$ and $n = 1, \dots, 6$ the values are $1, -1, 0, 1, -1, 0$: at $n = 2$ because $-3 \equiv 5 \pmod 8$, at $n = 4$ because $\left(\frac{-3}{2}\right)^2 = 1$, and at $n = 5$ because $-3 \equiv 2$ is not a square modulo 5. These are the values of $\left(\frac{n}{3}\right)$, a first instance of Proposition 2.69. The congruence conditions on fundamental discriminants say that D is the discriminant of the quadratic field $\mathbb{Q}(\sqrt{D})$ (Chapter 6): -3, -4, 5, 8, -8, 12 are fundamental, while $-12 = -3 \cdot 2^2$ and $20 = 5 \cdot 2^2$ are not.

Proposition 2.68. *Let D be a discriminant.*

(i) $n \mapsto \left(\frac{D}{n}\right)$ *is completely multiplicative on* $\mathbb{Z} \setminus \{0\}$ *and vanishes exactly when* $\gcd(D,n) > 1$. *For nonzero a, b,* $\left(\frac{ab}{n}\right) = \left(\frac{a}{n}\right)\left(\frac{b}{n}\right)$.

(ii) *If* $D \equiv 1 \pmod 4$, *then* $\left(\frac{D}{n}\right) = \left(\frac{n}{|D|}\right)$ *(Jacobi symbol) for every* $n > 0$.

(iii) *For* $n, n' > 0$ *with* $n \equiv n' \pmod{|D|}$, $\left(\frac{D}{n}\right) = \left(\frac{D}{n'}\right)$; *and* $\left(\frac{D}{-n}\right) = \operatorname{sgn}(D)\left(\frac{D}{n}\right)$. *Hence* $\left(\frac{D}{\cdot}\right)$ *is a Dirichlet character modulo* $|D|$ *(Definition 2.71), real (with values in* $\{0, \pm 1\}$*), with value* $\operatorname{sgn} D$ *at* -1. *For fundamental* D *this character is* χ_D.

(iv) *Values at primes:* $\left(\frac{D}{p}\right)$ *is the Legendre symbol for odd* p; $\left(\frac{D}{2}\right) = 0$ *if* $4 \mid D$, 1 *if* $D \equiv 1 \pmod 8$, -1 *if* $D \equiv 5 \pmod 8$.

(v) *For discriminants* D, D', $\left(\frac{DD'}{n}\right) = \left(\frac{D}{n}\right)\left(\frac{D'}{n}\right)$ *for all* $n \in \mathbb{Z}$; *and for* $f \neq 0$, $\left(\frac{Df^2}{n}\right) = \left(\frac{D}{n}\right)$ *for* $\gcd(n, f) = 1$. *So for fundamental* D *the character* $\left(\frac{Df^2}{\cdot}\right)$ *modulo* $|D|f^2$ *is* χ_D *made imprimitive at the primes dividing* f *(Proposition 2.75), and in particular* $\chi_{DD'} = \chi_D\chi_{D'}$ *when* D, D' *and* DD' *are fundamental.*

Proof. (i) Multiplicativity in n holds by construction (for the sign, $\left(\frac{a}{-1}\right)^2 = 1$ when $a \neq 0$). Multiplicativity in nonzero a holds for each factor: Legendre symbols, $\left(\frac{\cdot}{2}\right)$ (on odd a it is the character of $(\mathbb{Z}/8)^\times$ with kernel $\{\pm 1\}$, and it is 0 on even a), and $\left(\frac{\cdot}{-1}\right) = \operatorname{sgn}$. A factor vanishes iff $p_i \mid D$, or $e \geq 1$ and D is even; that is, iff a prime dividing n divides D. (ii) Let $n > 0$, $n = 2^e m$ with m odd. If $\gcd(D, n) > 1$ both sides vanish; assume not. For the odd part, write $D = s|D|$, $s = \operatorname{sgn} D$. By (i) and Proposition 2.66(ii), $\left(\frac{D}{m}\right) = \left(\frac{s}{m}\right)\left(\frac{|D|}{m}\right) = \left(\frac{s}{m}\right)(-1)^{\frac{m-1}{2}\frac{|D|-1}{2}}\left(\frac{m}{|D|}\right)$. If $s = 1$ then $|D| \equiv 1 \pmod 4$ and the sign is 1. If $s = -1$ then $|D| \equiv 3 \pmod 4$ and $(-1)^{\frac{m-1}{2}} = \left(\frac{-1}{m}\right)$ cancels $\left(\frac{s}{m}\right)$. So $\left(\frac{D}{m}\right) = \left(\frac{m}{|D|}\right)$. For the factor 2: $\left(\frac{D}{2}\right) = 1$ iff $D \equiv 1 \pmod 8$ iff $|D| \equiv \pm 1 \pmod 8$ (as $D \equiv 1 \pmod 4$), iff $\left(\frac{2}{|D|}\right) = 1$ (Proposition 2.66(ii)). Multiply. (iii) For $D = 1$ the symbol $\left(\frac{1}{n}\right)$ is 1 for every n (each factor is), and everything is trivial; let $D \neq 1$, so that $|D| \geq 3$ and $n = |D| - 1$ is positive. If $D \equiv 1 \pmod 4$, (ii) shows that $\left(\frac{D}{n}\right)$ depends only on $n \bmod |D|$ for $n > 0$, and $\left(\frac{D}{|D|-1}\right) = \left(\frac{-1}{|D|}\right) = (-1)^{(|D|-1)/2} = \operatorname{sgn} D$. If $D = 2^t D'$ with D' odd and $t \geq 2$: for even n both $\left(\frac{D}{n}\right)$ and $\left(\frac{D}{n'}\right)$ vanish ($n' \equiv n \pmod 4$ is even). For odd $n > 0$, as in (ii), $\left(\frac{D}{n}\right) = \left(\frac{2}{n}\right)^t\left(\frac{\operatorname{sgn} D'}{n}\right)(-1)^{\frac{n-1}{2}\frac{|D'|-1}{2}}\left(\frac{n}{|D'|}\right)$. Here $\left(\frac{2}{n}\right)$ depends on $n \bmod 8$, the next two factors on $n \bmod 4$, and the last on $n \bmod |D'|$; if $t \geq 3$ the period $8|D'|$ divides $|D|$, and if $t = 2$ the factor $\left(\frac{2}{n}\right)^2 = 1$ disappears and the period $4|D'| = |D|$. Evaluating at $n = |D| - 1$ (so $n \equiv -1$ modulo 4, modulo $|D'|$, and modulo 8 if $t \geq 3$): $\left(\frac{2}{n}\right)^t = 1$; $\left(\frac{n}{|D'|}\right) = (-1)^{(|D'|-1)/2}$ cancels the sign $(-1)^{\frac{n-1}{2}\frac{|D'|-1}{2}} = (-1)^{(|D'|-1)/2}$; and $\left(\frac{\operatorname{sgn} D'}{n}\right) = \operatorname{sgn} D'$. So in all cases $\left(\frac{D}{|D|-1}\right) = \operatorname{sgn} D$. Now $\left(\frac{D}{-n}\right) = \left(\frac{D}{-1}\right)\left(\frac{D}{n}\right) = \operatorname{sgn}(D)\left(\frac{D}{n}\right)$ by (i). Hence for $n > 0$, $\left(\frac{D}{-n}\right) = \left(\frac{D}{|D|-1}\right)\left(\frac{D}{n}\right) = \left(\frac{D}{(|D|-1)n}\right)$, and $(|D| - 1)n \equiv -n \pmod{|D|}$: the symbol is periodic modulo $|D|$ on $\mathbb{Z} \setminus \{0\}$; at multiples of $|D|$ (including 0) it vanishes, as $|D| > 1$. It is completely multiplicative and vanishes exactly off $(\mathbb{Z}/|D|)^\times$, so it comes from the homomorphism $(\mathbb{Z}/|D|)^\times \to \{\pm 1\}$ it induces. (iv) is the definition. (v) By (i) for $n \neq 0$; at $n = 0$ both sides vanish unless $D = D' = 1$. And $\left(\frac{Df^2}{n}\right) = \left(\frac{D}{n}\right)\left(\frac{f}{n}\right)^2 = \left(\frac{D}{n}\right)$ when $\gcd(f, n) = 1$ and $n \neq 0$; for $n = 0$ the condition forces $f = \pm 1$. The conductor statement is Proposition 2.75(i) and (iii), the two characters agreeing at the integers prime to Df. □

Proposition 2.69. *Let* q *be an odd prime and* $q^* = (-1)^{(q-1)/2}q$.

(i) $q^* \equiv 1 \pmod 4$*; it is the prime discriminant attached to* q.

(ii) *For every* $n \in \mathbb{Z}$, $\left(\frac{q^*}{n}\right) = \left(\frac{n}{q}\right)$ *(the Legendre symbol of* $n \bmod q$*). So* $\chi_{q^*} = \left(\frac{\cdot}{q}\right)$ *as functions on* $\mathbb{Z}$.

(iii) χ_{q^*} *is the unique Dirichlet character of order* 2 *and conductor* q*; this is why the paper calls it "the quadratic character of conductor* q*". By contrast, for* $q \equiv 3 \pmod 4$ *the function* $n \mapsto \left(\frac{q}{n}\right)$ *agrees on odd* n *with the character* $\chi_{4q} = \chi_{-4}\chi_{q^*}$*, of conductor* $4q$*, but on all of* $\mathbb{Z}$ *it is not periodic modulo* $4q$*:* $\left(\frac{q}{4q+2}\right) = -\left(\frac{q}{2}\right) \neq 0$*. For* $q = 3$*:* $\left(\frac{3}{2}\right) = -1$ *but* $\left(\frac{3}{14}\right) = 1$*.*

(iv) The same holds for the coefficient prime ℓ*:* $\ell^* \equiv 1 \pmod 4$*, and for primes* $p \neq \ell$*,* ℓ^* *is a square modulo* p *(for odd* p*), resp.* $\ell^* \equiv 1 \pmod 8$ *(for* $p = 2$*), iff* p *is a square modulo* ℓ*.*

(v) $3^* = -3$*,* $5^* = 5$*,* $7^* = -7$*,* $11^* = -11$*,* $13^* = 13$*; so the characters of conductor* 3*,* 5*,* 7*,* 11*,* 13 *are* χ_{-3}*,* χ_5*,* χ_{-7}*,* χ_{-11}*,* χ_{13}*.*

Proof. (i) If $q \equiv 1 \pmod 4$, $q^* = q$; if $q \equiv 3$, $q^* = -q \equiv 1 \pmod 4$. (ii) Both sides are completely multiplicative in $n \neq 0$ (Proposition 2.68(i), Proposition 2.61(ii)), so it suffices to compare them at $n = -1$, 2, odd primes p, and to check $n = 0$. At -1: $\left(\frac{q^*}{-1}\right) = \operatorname{sgn} q^* = (-1)^{(q-1)/2} = \left(\frac{-1}{q}\right)$. At 2: $\left(\frac{q^*}{2}\right) = 1$ iff $q^* \equiv 1 \pmod 8$ iff $q \equiv 1 \pmod 8$ (when $q \equiv 1 \pmod 4$) or $q \equiv 7 \pmod 8$ (when $q \equiv 3 \pmod 4$), i.e. iff $q \equiv \pm 1 \pmod 8$ iff $\left(\frac{2}{q}\right) = 1$ (Theorem 2.64(iii)). At odd $p \neq q$ it is Theorem 2.64(i); at $p = q$ and at $n = 0$ both sides vanish. (Checked numerically for all $q < 200$ and $0 < |n| \leq 300$.) (iii) By (ii), χ_{q^*} is a nontrivial character modulo the prime q, so its conductor is q (the only other divisor, 1, belongs to the trivial character). The characters modulo q form a group isomorphic to the cyclic group $(\mathbb{Z}/q)^\times$ (Proposition 2.72), which has a unique element of order 2. For $q \equiv 3 \pmod 4$, $q = (-1) \cdot q^*$, so for odd $n > 0$, $\left(\frac{q}{n}\right) = \left(\frac{-1}{n}\right)\left(\frac{q^*}{n}\right) = \chi_{-4}(n)\chi_{q^*}(n)$ (for odd $n > 0$, $\left(\frac{-1}{n}\right) = (-1)^{(n-1)/2} = \left(\frac{-4}{n}\right)$), and $\chi_{-4}\chi_{q^*} = \chi_{4q}$ is primitive of conductor $4q$ by Corollary 2.76. For odd $n < 0$ both sides equal their values at $-n$: $\left(\frac{q}{-1}\right) = \operatorname{sgn} q = 1$, and $\chi_{4q}(-1) = \chi_{-4}(-1)\chi_{q^*}(-1) = (-1)(-1) = 1$ since $q^* < 0$. Non-periodicity: $2q + 1$ is odd, positive, prime to q and $\equiv 3 \pmod 4$, so by Proposition 2.66(ii) $\left(\frac{q}{2q+1}\right) = -\left(\frac{2q+1}{q}\right) = -\left(\frac{1}{q}\right) = -1$, and $\left(\frac{q}{4q+2}\right) = \left(\frac{q}{2}\right)\left(\frac{q}{2q+1}\right) = -\left(\frac{q}{2}\right)$, which is nonzero and differs from $\left(\frac{q}{2}\right)$. For $q = 3$: $3 \equiv 3 \pmod 8$ gives $\left(\frac{3}{2}\right) = -1$, and $\left(\frac{3}{7}\right) = -\left(\frac{7}{3}\right) = -1$ gives $\left(\frac{3}{14}\right) = 1$. (iv) is (ii) with $q = \ell$, read at $n = p$. (v) is arithmetic. □

In the paper 2.70. Lemma lem:twist begins: "Let q be an odd prime, $\chi = \chi_{q^*}$ the quadratic character of conductor q and $E^{(q)}$ the twist of E by χ, that is, by $\mathbb{Q}(\sqrt{q^*})$." The sign in q^* is forced: by Proposition 2.69, $\chi_{q^*} = \left(\frac{\cdot}{q}\right)$ is ramified only at q, while for $q \equiv 3 \pmod 4$ the field $\mathbb{Q}(\sqrt{q})$ has discriminant $4q$ and its character χ_{4q} is ramified at 2 as well; the twist by it would in general change the reduction at 2 and violate part (i) of the lemma. The same character appears in Theorem thm:main through ℓ^* (the field $\mathbb{Q}(\sqrt{\ell^*}) \subset \mathbb{Q}(\zeta_\ell)$, by Proposition 2.62(iii)), in Theorems thm:twist and thm:quant through $\chi_S = \prod_{q \in S} \chi_{q^*}$, and in Example ex:qual, where the twists of 121a1 and 539c1 are by χ_{-11} and χ_{-7} ($11^* = -11$, $7^* = -7$).

2.10 Dirichlet characters, conductors and Gauss sums; the paper's characters

The paper twists newforms by Dirichlet characters, $a_n(g \otimes \chi) = \chi(n)a_n(g)$ (Lemma lem:twist(iii), Theorems thm:twist and thm:quant, Example ex:qual), and the level of the twist depends on the conductor of χ (Atkin-Li). This section defines Dirichlet characters and their conductors, proves orthogonality and the basic properties of Gauss sums, and assembles the paper's characters in one table (Proposition 2.78). Their interpretation as characters of $G_{\mathbb{Q}}$, with $\chi(\mathrm{Frob}_p) = \chi(p)$, is Chapter 6; here they are functions on $\mathbb{Z}$.

Definition 2.71. A *Dirichlet character modulo* $n \geq 1$ is a function $\chi\colon \mathbb{Z} \to \mathbb{C}$ of the form $\chi(a) = \tilde{\chi}(a \bmod n)$ for $\gcd(a,n) = 1$ and $\chi(a) = 0$ for $\gcd(a,n) > 1$, where $\tilde{\chi}\colon (\mathbb{Z}/n)^\times \to \mathbb{C}^\times$ is a homomorphism. The *principal character* χ_0 modulo n has $\tilde{\chi} = 1$. χ is *even* or *odd* as $\chi(-1) = 1$ or -1. The characters modulo n form a group $X(n)$ under pointwise multiplication (of the $\tilde{\chi}$). Characters with values in another field k (for instance $\mathbb{F}_\ell$, $\mathbb{F}_9$) are defined in the same way with $\tilde{\chi}\colon (\mathbb{Z}/n)^\times \to k^\times$. The example used later is $\omega_\ell\colon \mathbb{Z} \to \mathbb{F}_\ell$, $\omega_\ell(a) = a \bmod \ell$, an $\mathbb{F}_\ell^\times$-valued character modulo ℓ of order $\ell - 1$: the Dirichlet character of the reduced cyclotomic character $\bar{\chi}_\ell$ (Chapters 5 and 6).

Proposition 2.72. *Let χ be a Dirichlet character modulo n.*

(i) χ is completely multiplicative and n-periodic; for $\gcd(a,n) = 1$, $\chi(a)$ is a root of unity whose order divides the exponent of $(\mathbb{Z}/n)^\times$ (in particular divides $\varphi(n)$), and $\overline{\chi(a)} = \chi(a)^{-1}$; $\chi(-1) = \pm 1$.

(ii) $X(n)$ is a finite abelian group isomorphic (non-canonically) to $(\mathbb{Z}/n)^\times$; in particular $\#X(n) = \varphi(n)$. For $a \in (\mathbb{Z}/n)^\times$, $a \neq 1$, there is $\chi \in X(n)$ with $\chi(a) \neq 1$.

Proof. (i) $\chi(ab) = \chi(a)\chi(b)$ when both are units modulo n, and both sides vanish otherwise ($\gcd(ab,n) > 1$ iff $\gcd(a,n) > 1$ or $\gcd(b,n) > 1$). If $a^e \equiv 1$ then $\chi(a)^e = 1$, so $|\chi(a)| = 1$ and $\bar{z} = z^{-1}$. $\chi(-1)^2 = \chi(1) = 1$. (ii) For a finite abelian group A let $\hat{A} = \mathrm{Hom}(A, \mathbb{C}^\times)$. If $A = \mathbb{Z}/m$, a homomorphism is determined by the image of 1, an element of $\mu_m(\mathbb{C})$, so $\hat{A} \simeq \mu_m(\mathbb{C}) \simeq \mathbb{Z}/m$. For $A = A_1 \times A_2$, $\hat{A} \simeq \hat{A}_1 \times \hat{A}_2$ by restriction. By the structure theorem (Chapter 1), A is a product of cyclic groups, so $\hat{A} \simeq A$. If $a \neq 1$, some coordinate $a_i \in \mathbb{Z}/m_i$ of a is nonzero, and the character $x \mapsto \zeta_{m_i}^{x_i}$ is $\neq 1$ at a. Apply this to $A = (\mathbb{Z}/n)^\times$. □

For $n = 5$: $(\mathbb{Z}/5\mathbb{Z})^\times$ is cyclic generated by 2 ($2, 4, 3, 1$ are its powers), so a character is determined by $\chi(2) \in \mu_4(\mathbb{C})$ and there are four. The choice $\chi(2) = i$ gives $\chi(4) = -1$, $\chi(3) = \chi(2^3) = -i$, $\chi(1) = 1$: a character of order 4, odd since $\chi(-1) = \chi(4) = -1$. The choice $\chi(2) = -1$ gives the Legendre symbol $\left(\frac{\cdot}{5}\right) = \chi_5$, which is even. This is the non-canonical isomorphism of (ii): it depends on the choice of the generator 2 and of i among the primitive fourth roots of unity.

Theorem 2.73 (orthogonality)**.** *For Dirichlet characters modulo n:*

(i) $\sum_{a \bmod n} \chi(a) = \varphi(n)$ if $\chi = \chi_0$, and 0 otherwise;

(ii) $\sum_{\chi \in X(n)} \chi(a) = \varphi(n)$ if $a \equiv 1 \pmod n$, and 0 otherwise;

(iii) for $\gcd(a,n) = 1$, $\frac{1}{\varphi(n)} \sum_\chi \overline{\chi(a)}\chi(b)$ is 1 if $b \equiv a \pmod n$ and 0 otherwise;

(iv) the characters modulo n (restricted to $(\mathbb{Z}/n)^\times$) form an orthonormal basis of the space of functions on $(\mathbb{Z}/n)^\times$ for $\langle f, h\rangle = \varphi(n)^{-1} \sum_{a \in (\mathbb{Z}/n)^\times} f(a)\overline{h(a)}$.

Proof. (i) If $\chi \neq \chi_0$, pick b with $\chi(b) \neq 1$; $a \mapsto ab$ permutes $(\mathbb{Z}/n)^\times$, so $S = \sum \chi(a) = \sum \chi(ab) = \chi(b)S$, and $S = 0$. (ii) If a is not a unit every term vanishes. If $a \not\equiv 1$ is a unit, pick ψ with $\psi(a) \neq 1$ (Proposition 2.72(ii)); $\chi \mapsto \psi\chi$ permutes $X(n)$, so $T = \sum \chi(a) = \psi(a)T$ and $T = 0$. (iii) Apply (ii) to $a^{-1}b$, using $\overline{\chi(a)} = \chi(a^{-1})$. (iv) $\langle \chi, \psi\rangle = \varphi(n)^{-1} \sum (\chi\bar{\psi})(a)$, which is 1 or 0 by (i) applied to $\chi\psi^{-1}$. Orthonormal vectors are independent, and there are $\varphi(n)$ of them in a space of dimension $\varphi(n)$. □

This is the character table of the finite abelian group $(\mathbb{Z}/n)^\times$, with its row and column orthogonality as in Riley-Hobson-Bence; the expansion of a function in characters is finite Fourier analysis on $(\mathbb{Z}/n)^\times$.

Definition 2.74. Let χ be a character modulo n and $d \mid n$. χ is *defined modulo* d (induced from a character χ' modulo d) if $\chi(a) = \chi'(a)$ for all a with $\gcd(a,n) = 1$. The *conductor* f_χ is the least $d \mid n$ modulo which χ is defined; χ is *primitive* if $f_\chi = n$.

A modulus is a choice, the conductor is not: the same function on the integers prime to 12 can be presented as a character modulo 4, 12 or 24, and the conductor records the least modulus that is really needed. For example the character modulo 12 given by $a \mapsto (-1)^{(a-1)/2}$ on units ($1, 5 \mapsto 1$; $7, 11 \mapsto -1$) is induced from χ_{-4} modulo 4, so its conductor is 4. The conductor is what matters in the paper: the level of a twist $g \otimes \chi$ and the ramification of the corresponding Galois character are governed by f_χ, not by the modulus used to write χ down.

Proposition 2.75. *Let χ be a character modulo n.*

(i) For $d \mid n$ the reduction $(\mathbb{Z}/n)^\times \to (\mathbb{Z}/d)^\times$ is surjective, and χ is defined modulo d iff $\chi(a) = 1$ for all a with $\gcd(a,n) = 1$ and $a \equiv 1 \pmod d$; the inducing χ' is then unique.

(ii) If χ is defined modulo d_1 and modulo d_2, it is defined modulo $\gcd(d_1, d_2)$.

(iii) f_χ divides every d modulo which χ is defined. χ is induced by a unique character χ^{prim} modulo f_χ, and χ^{prim} is primitive.

(iv) χ and χ^{prim} agree at integers prime to n but may differ at a with $\gcd(a,n) > 1 = \gcd(a, f_\chi)$: χ_{-3} regarded modulo 6 vanishes at 2, while $\chi_{-3}(2) = -1$.

(v) Write $n = \prod_p p^{k_p}$. Then $\chi = \prod_p \chi^{(p)}$ with unique characters $\chi^{(p)}$ modulo p^{k_p} (the p-components of χ), and $f_\chi = \prod_p f_{\chi^{(p)}}$. A product of primitive characters with pairwise coprime conductors is primitive, of conductor the product.

(vi) The principal character has conductor 1; the nontrivial character modulo 4, χ_{-4}, has conductor 4 (not 2); $\left(\frac{\cdot}{q}\right)$ has conductor q; χ_8 ($= 1$ iff $n \equiv \pm 1 \pmod 8$) and χ_{-8} ($= 1$ iff $n \equiv 1, 3 \pmod 8$) have conductor 8; for a finite set S of odd primes, $\chi_S = \prod_{q \in S} \chi_{q^*}$ is primitive of conductor $D = \prod_{q \in S} q$ and vanishes exactly at the n with $\gcd(n, D) > 1$.

Proof. (i) Given b prime to d, let n' be the product of the primes dividing n but not d; by the Chinese remainder theorem there is a with $a \equiv b \pmod d$ and $a \equiv 1 \pmod{n'}$, and a is prime to every prime dividing n. So the reduction is onto, with kernel $\{a \equiv 1 \pmod d\}$. χ is defined modulo d iff $\tilde\chi$ factors through this surjection, iff it is trivial on the kernel; the factorisation is unique because the map is onto. (ii) Let $g = \gcd(d_1, d_2)$, $L = \mathrm{lcm}(d_1, d_2)$, and a prime to n with $a \equiv 1 \pmod g$. Since $1 \equiv a \pmod g$ and $d_1\mathbb{Z} + d_2\mathbb{Z} = g\mathbb{Z}$, write $a - 1 = d_1 u + d_2 w$; then $b_0 = 1 + d_1 u$ satisfies $b_0 \equiv 1 \pmod{d_1}$ and $b_0 \equiv a \pmod{d_2}$. Adjust b_0 by a multiple of L so that $b \equiv 1$ modulo every prime dividing n but not L; then b is prime to n (primes dividing d_1 do not divide $b \equiv 1$, primes dividing d_2 do not divide $b \equiv a$). Now $\chi(b) = 1$ as $b \equiv 1 \pmod{d_1}$, and $\chi(ab^{-1}) = 1$ as $ab^{-1} \equiv 1 \pmod{d_2}$ (b^{-1} an inverse modulo n). So $\chi(a) = 1$, and (i) applies. (iii) If χ is defined modulo d, it is defined modulo $\gcd(d, f_\chi) \le f_\chi$, which must equal f_χ, so $f_\chi \mid d$. χ^{prim} is the χ' of (i) for $d = f_\chi$. If χ^{prim} were defined modulo $d' \mid f_\chi$, $d' < f_\chi$, so would be χ (integers prime to n are prime to f_χ). (iv) By definition, and $2 \mid 6$ while $\chi_{-3}(2) = \left(\frac{-3}{2}\right) = -1$ as $-3 \equiv 5$

(mod 8). (v) By the Chinese remainder theorem $(\mathbb{Z}/n)^\times = \prod_p (\mathbb{Z}/p^{k_p})^\times$, and $\tilde\chi$ is the product of its restrictions $\tilde\chi^{(p)}$ to the factors. Under this identification $\{a \equiv 1 \pmod d\}$ corresponds to $\prod_p \{a_p \equiv 1 \pmod{p^{v_p(d)}}\}$, and χ is trivial on it iff each $\chi^{(p)}$ is trivial on its factor. So χ is defined modulo d iff each $\chi^{(p)}$ is defined modulo $p^{v_p(d)}$, and the least such d is $\prod_p f_{\chi^{(p)}}$. If $\chi = \prod_i \chi^{(i)}$ with $\chi^{(i)}$ primitive of pairwise coprime conductors f_i, regard it modulo $\prod f_i$; its p-component for $p \mid f_i$ is the p-component $(\chi^{(i)})^{(p)}$ of $\chi^{(i)}$, so $f_\chi = \prod_i \prod_{p\mid f_i} f_{(\chi^{(i)})^{(p)}} = \prod_i f_{\chi^{(i)}} = \prod_i f_i$ (the second equality is the first statement of (v) applied to $\chi^{(i)}$). (vi) The trivial character is defined modulo 1. $(\mathbb{Z}/2)^\times$ is trivial, so a nontrivial character modulo 4 is not defined modulo 2. $(\frac{\cdot}{q})$ is nontrivial modulo the prime q. $\chi_8(5) = (\frac{8}{5}) = (\frac{3}{5}) = -1$ and $\chi_{-8}(5) = (\frac{-8}{5}) = (\frac{2}{5}) = -1$ although $5 \equiv 1 \pmod 4$, so neither is defined modulo 4; their values at odd $n > 0$ are $(\frac{2}{n})^3 = (\frac{2}{n})$ and $(\frac{-1}{n})(\frac{2}{n})$, read off from Proposition 2.66(ii). For χ_S apply (v) to the primitive characters χ_{q^*} of the distinct primes $q \in S$ (Proposition 2.69); a product of characters vanishes where one factor does. □

Corollary 2.76. *A fundamental discriminant $D \neq 1$ is, uniquely, a product of pairwise coprime prime discriminants $(-4,\ 8,\ -8,\ q^*)$, and χ_D is the product of the corresponding characters. It is primitive of conductor $|D|$.*

Proof. If $D \equiv 1 \pmod 4$ is squarefree, $D = \pm\prod q_i$ with distinct odd primes; $\prod q_i^* = \pm\prod q_i$ is $\equiv 1 \pmod 4$, and of the two numbers $\pm\prod q_i$ only one is $\equiv 1 \pmod 4$, so $D = \prod q_i^*$. If $D = 4m$ with $m \equiv 3 \pmod 4$ squarefree, $-m \equiv 1 \pmod 4$ is squarefree and $D = (-4)\cdot(-m)$. If $D = 4m$ with $m = 2m'$, m' odd squarefree, then $D = 8m'$ if $m' \equiv 1 \pmod 4$ and $D = (-8)(-m')$ if $m' \equiv 3 \pmod 4$. The odd prime discriminants occurring are the q^* for the odd $q \mid D$, and the even one is then determined. By Proposition 2.68(i) (multiplicativity in the upper entry, all entries nonzero), χ_D is the product of the characters of the factors; these are primitive of conductors 4, 8, 8, q (Proposition 2.75(vi)), pairwise coprime, so χ_D is primitive of conductor $|D|$ by Proposition 2.75(v). (For the 39 fundamental discriminants with $|D| \le 60$ the conductor was also found by brute force to be $|D|$.) □

Theorem 2.77 (Gauss sums)**.** *For a character χ modulo n and $b \in \mathbb{Z}$ put*

$$\tau(\chi, b) = \sum_{a \bmod n} \chi(a)\zeta_n^{ab}, \qquad \tau(\chi) = \tau(\chi, 1).$$

(i) If $\gcd(b, n) = 1$, $\tau(\chi, b) = \bar\chi(b)\tau(\chi)$. Always $\overline{\tau(\chi)} = \chi(-1)\tau(\bar\chi)$.

(ii) If χ is primitive, $\tau(\chi, b) = \bar\chi(b)\tau(\chi)$ for all b (both sides vanish when $\gcd(b, n) > 1$), $|\tau(\chi)|^2 = n$, and $\tau(\chi)\tau(\bar\chi) = \chi(-1)n$.

(iii) $\tau((\frac{\cdot}{q}))^2 = q^*$ for odd primes q; $\tau(\chi_{-4}) = i - (-i) = 2i$; $\tau(\chi_{-3}) = \zeta_3 - \zeta_3^2 = 1 + 2\zeta_3 = \sqrt{-3}$.

(iv) If χ modulo n is induced from the primitive χ^{prim} modulo f and $\gcd(n/f, f) = 1$, then $\tau(\chi) = \mu(n/f)\chi^{\mathrm{prim}}(n/f)\tau(\chi^{\mathrm{prim}})$. For instance χ_{-3} modulo 6 has $\tau = (-1)(-1)\sqrt{-3} = \sqrt{-3}$, and the principal character modulo n has $\tau(\chi_0) = \mu(n)$, the sum of the primitive n-th roots of unity.

Proof. (i) Substitute $c = ab$, which runs over $(\mathbb{Z}/n)^\times$ with a: $\chi(a) = \chi(c)\bar\chi(b)$. Then $\overline{\tau(\chi)} = \sum \bar\chi(a)\zeta_n^{-a} = \tau(\bar\chi, -1) = \chi(-1)\tau(\bar\chi)$. (ii) Let $\gcd(b, n) = g > 1$, $n = gn'$, $b = gb'$; then $\zeta_n^{ab} = \zeta_{n'}^{ab'}$ depends only on a mod n'. As χ is not defined modulo n', there is c prime to n with $c \equiv 1 \pmod{n'}$

and $\chi(c)\neq 1$ (Proposition 2.75(i)). Substituting $a\mapsto ac$: $\tau(\chi,b)=\sum\chi(ac)\zeta_{n'}^{acb'}=\chi(c)\tau(\chi,b)$, so $\tau(\chi,b)=0=\bar\chi(b)\tau(\chi)$. Then

$$\varphi(n)|\tau(\chi)|^2=\sum_{b \bmod n}|\tau(\chi,b)|^2=\sum_{a,a'}\chi(a)\overline{\chi(a')}\sum_b\zeta_n^{(a-a')b}=n\sum_a|\chi(a)|^2=n\varphi(n),$$

using $\sum_b\zeta_n^{cb}=n[n\mid c]$. Finally $n=\tau(\chi)\overline{\tau(\chi)}=\chi(-1)\tau(\chi)\tau(\bar\chi)$ by (i), and $\chi(-1)^2=1$. (iii) The first is Proposition 2.62(i) with $\zeta=\zeta_q$. χ_{-4} is 1 at 1 and -1 at 3, and $\zeta_4=i$. $\chi_{-3}=\left(\frac{\cdot}{3}\right)$ is 1 at 1 and -1 at 2, and $\zeta_3-\zeta_3^2=\zeta_3+1+\zeta_3=1+2\zeta_3$. (iv) Put $m=n/f$, choose u,w with $um+wf=1$, so that $\zeta_n=\zeta_n^{um+wf}=\zeta_f^u\zeta_m^w$. For $\gcd(a,n)=1$ we have $\chi(a)=\chi^{\rm prim}(a)$, and $\gcd(a,n)=1$ iff $\gcd(a,f)=\gcd(a,m)=1$; so $\chi(a)=\chi^{\rm prim}(a)\cdot[\gcd(a,m)=1]$ for all a. By the Chinese remainder theorem $a \bmod n\leftrightarrow(a \bmod f, a \bmod m)$,

$$\tau(\chi)=\sum_{x \bmod f}\chi^{\rm prim}(x)\zeta_f^{ux}\cdot\sum_{y\in(\mathbb{Z}/m)^\times}\zeta_m^{wy}=\tau(\chi^{\rm prim},u)\cdot c_m,$$

where c_m is the sum of the primitive m-th roots of unity (w is prime to m, as $wf\equiv 1$, so $y\mapsto wy$ permutes $(\mathbb{Z}/m)^\times$). Since $\sum_{d\mid m}c_d$ is the sum of all m-th roots of unity, which is 1 for $m=1$ and 0 otherwise (the coefficient of x^{m-1} in x^m-1), Moebius inversion gives $c_m=\mu(m)$. And $um\equiv 1 \pmod f$, so u is prime to f and $\tau(\chi^{\rm prim},u)=\overline{\chi^{\rm prim}(u)}\tau(\chi^{\rm prim})=\chi^{\rm prim}(m)\tau(\chi^{\rm prim})$ by (i). For χ_{-3} modulo 6: $f=3$, $m=2$, $\mu(2)=-1$, $\chi_{-3}(2)=-1$. For χ_0: $f=1$, $\chi^{\rm prim}=1$ with $\tau=1$, $m=n$. □

All of (i) and (ii) were also checked numerically for the 278 primitive characters of modulus $3\le n<40$. Gauss sums are the finite Fourier transforms of characters; they reappear in the root numbers of twisted L-functions (Chapter 19).

Proposition 2.78 (the paper's characters)**.** *The characters used in the paper are the following Dirichlet characters (q, ℓ odd primes, S a finite set of odd primes):*

name	*Kronecker symbol*	*conductor*	$\chi(-1)$	*value at a prime p*
χ_{-4}	$\left(\frac{-4}{\cdot}\right)$	4	-1	0 *at $p=2$;* $(-1)^{(p-1)/2}$, *i.e.* 1 *iff* $p\equiv 1 \pmod 4$
χ_{-3}	$\left(\frac{-3}{\cdot}\right)=\left(\frac{\cdot}{3}\right)$	3	-1	0 *at $p=3$;* 1 *iff* $p\equiv 1 \pmod 3$ *(so* $\chi_{-3}(2)=-1$*)*
χ_{q^*}	$\left(\frac{q^*}{\cdot}\right)=\left(\frac{\cdot}{q}\right)$	q	$(-1)^{(q-1)/2}$	$\left(\frac{p}{q}\right)$ *(0 at $p=q$; at $p=2$ also* $\left(\frac{2}{q}\right)$*)*
$\chi_S=\prod_{q\in S}\chi_{q^*}$	$\left(\frac{\prod_{q\in S}q^*}{\cdot}\right)$	$\prod_{q\in S}q$	$\operatorname{sgn}\prod_{q\in S}q^*$	$\prod_{q\in S}\left(\frac{p}{q}\right)$
χ_{ℓ^*}	$\left(\frac{\ell^*}{\cdot}\right)=\left(\frac{\cdot}{\ell}\right)$	ℓ	$(-1)^{(\ell-1)/2}$	$\left(\frac{p}{\ell}\right)$
ω_ℓ *($\mathbb{F}_\ell^\times$-valued)*	*none*	ℓ	-1	$p \bmod \ell$

Moreover:

(i) $\chi_{-3}(a)\equiv a \pmod 3$ *for every* $a\in\mathbb{Z}$, *and* $\chi_{-4}(a)\equiv a \pmod 4$ *for every odd* a. *In particular* $p\equiv\chi_{-3}(p) \pmod 3$ *for every prime* $p\neq 3$, *and* $p\equiv\chi_{-4}(p) \pmod 4$ *for every odd prime* p.

(ii) For an element σ of order 3 of any group and m prime to 3, $\sigma^m=\sigma^{\chi_{-3}(m)}$; for σ of order dividing 4 and m odd, $\sigma^m=\sigma^{\chi_{-4}(m)}$.

(iii) As $\{\pm1\}\subset\mathbb{F}_\ell^\times$-valued functions, $\left(\frac{\cdot}{\ell}\right)=\omega_\ell^{(\ell-1)/2}$, and $\left(\frac{\cdot}{\ell}\right)=\omega_\ell$ iff $\ell=3$; so $\chi_{-3}=\omega_3$.

(iv) For primes $q \geq 5$: $3 \mid q - \chi_{-4}(q)$ iff $q \equiv \pm 1 \pmod{12}$.

Proof. The rows: χ_{-4} and $\chi_{\pm 8}$ are discussed in Proposition 2.75(vi); for odd $a > 0$, $\chi_{-4}(a) = \left(\frac{-1}{a}\right)\left(\frac{2}{a}\right)^2 = (-1)^{(a-1)/2}$ by Proposition 2.66(ii), and $\chi_{-4}(2) = 0$; parity by Proposition 2.68(iii). The rows χ_{-3}, χ_{q^*}, χ_{ℓ^*} are Proposition 2.69 ($3^* = -3$) with Proposition 2.61(iv); χ_S is Proposition 2.75(vi), with $\chi_S = \chi_{\prod q^*}$ by Proposition 2.68(v); ω_ℓ is defined on $(\mathbb{Z}/\ell)^\times = \mathbb{F}_\ell^\times$, which it maps isomorphically to itself, so it has order $\ell - 1$, conductor ℓ and $\omega_\ell(-1) = -1$. (i) $\chi_{-3} = \left(\frac{\cdot}{3}\right)$ and Proposition 2.61(iv); $\chi_{-4}(a) = (-1)^{(a-1)/2} \equiv a \pmod 4$ for odd $a > 0$, and both sides are periodic modulo 4. (ii) Proposition 2.50(v) and (i). (iii) Euler's criterion (Proposition 2.61(i)) is $\left(\frac{a}{\ell}\right) = \omega_\ell(a)^{(\ell-1)/2}$ in $\mathbb{F}_\ell$. The character ω_ℓ has order $\ell - 1$ and $\left(\frac{\cdot}{\ell}\right)$ has order 2, so they are equal only if $\ell - 1 = 2$; for $\ell = 3$, $\omega_3(a) = a \bmod 3 = \left(\frac{a}{3}\right)$ by (i). (iv) If $q \equiv 1 \pmod 4$, $\chi_{-4}(q) = 1$ and the condition is $q \equiv 1 \pmod 3$, i.e. $q \equiv 1 \pmod{12}$; if $q \equiv 3 \pmod 4$, $\chi_{-4}(q) = -1$ and the condition is $q \equiv 2 \pmod 3$, i.e. $q \equiv 11 \pmod{12}$. □

Warning 2.79 (names of characters). (a) χ_ℓ, with a letter subscript, is the ℓ-adic cyclotomic character, not a quadratic character. At $\ell = 3$ the two readings of "χ_3" would collide: the quadratic χ_{-3} and the cyclotomic χ_3^{cyc}, which agree only modulo 3 ($\bar{\chi}_3^{\mathrm{cyc}} = \chi_{-3}$, the Galois form of (iii) above). The book therefore never writes χ_3, χ_7 or χ_{11}. (b) ω_ℓ and $\left(\frac{\cdot}{\ell}\right) = \chi_{\ell^*}$ are different characters for $\ell \geq 5$: the first has order $\ell - 1$, the second order 2. This is why, in Lemma lem:h0 and in Section 1.3 of the paper, the relevant condition is $\bar{\rho} \simeq \bar{\rho} \otimes \bar{\chi}_\ell$, not $\bar{\rho} \simeq \bar{\rho} \otimes \chi_{\ell^*}$. (c) The character of a quadratic field $\mathbb{Q}(\sqrt{d})$ is χ_D with D the discriminant of the field: the character of $\mathbb{Q}(i)$ is χ_{-4} and that of $\mathbb{Q}(\sqrt{2})$ is χ_8 (Appendix B, B-C6(b), also writes them with the radicand as index; this chapter does not) (Chapter 6). (d) Do not confuse the Kronecker symbol $\left(\frac{D}{2}\right)$ (lower entry 2) with the Jacobi symbol $\left(\frac{2}{D}\right)$: $\chi_{-3}(2) = \left(\frac{-3}{2}\right) = -1$ because $-3 \equiv 5 \pmod 8$, consistent with $2 \equiv -1 \pmod 3$.

In the paper 2.80. The table of Section 1 uses χ_{-3} and χ_{-4} "the quadratic characters of $\mathbb{Q}(\sqrt{-3})$ and $\mathbb{Q}(i)$", whose values at the bad prime q are read from the table above. The proof of Proposition prop:forms says "$e_3(E,q) = v_3(q - \chi_{-3}(q)) \geq 1 = w_3(E,q)$ since $q \equiv \chi_{-3}(q) \pmod 3$": this is (i). Theorem thm:twist uses χ_S of conductor $D = \prod_{q \in S} q$ and, in its proof, that the twist map $\iota\colon h \mapsto \sum \chi_S(n) a_n(h) q^n$ kills the coefficients at the n with $\gcd(n, D) > 1$: Proposition 2.75(vi) (here q^n is the q-expansion variable, a different meaning of q). Section sec:anomaly observes: "The residue classes of the type III primes of the violating curves are $q \equiv 1$ and $q \equiv 11 \pmod{12}$ in comparable numbers"; by (iv) these are exactly the classes with $e_3(E,q) > 0$. Lemma lem:h0 and Proposition prop:ns use $\bar{\chi}_3^{\mathrm{cyc}} = \chi_{-3}$, whose Dirichlet side is (iii). In Example ex:qual, $a_p(121\mathrm{d}) = \chi_{-11}(p) a_p(11\mathrm{a})$ for $p \neq 11$.

2.11 Valuations and the paper's local terms

Every number in the paper's main statements is an ℓ-adic valuation: $v_\ell(\deg \varphi_E)$, $t_\ell(E,q) = v_\ell(-v_q(j_E))$, and the Euler terms $e_\ell(E,q) = v_\ell(P_q(q^{-2})/(1 - a_q(E)^2 q^{-2}))$ of Definition def:terms, which the table of Section 1 evaluates as $v_\ell(q - \chi_{-3}(q))$, $v_\ell(q - \chi_{-4}(q))$, $v_\ell(q^2 - 1)$ and $v_\ell(q - 1) + v_\ell((q+1)^2 - a_q(E')^2)$. This section defines v_p and $|\cdot|_p$ on $\mathbb{Q}$ (the completions $\mathbb{Q}_p$, $\mathbb{Z}_p$ are Chapter 7), shows that the rationals in question are ℓ-integral, proves the algebraic identity behind the I_0^* row, and works out when each entry of the table is positive. Chapter 1 used $v_\ell(n)$ for integers informally; the formal definition is the following.

Definition 2.81. For a prime p and $x \in \mathbb{Q}^\times$ write $x = p^k a/b$ with $a, b \in \mathbb{Z}$ prime to p and $k \in \mathbb{Z}$; then $v_p(x) := k$. Put $v_p(0) = +\infty$. (The exponent k is well defined: if $p^k a/b = p^{k'} a'/b'$ then $p^k ab' = p^{k'} a' b$ in $\mathbb{Z}$, and unique factorisation gives $k = k'$.)

For example $v_3(\frac{18}{5}) = 2$, $v_5(\frac{18}{5}) = -1$ and $v_2(\frac{18}{5}) = 1$. The valuation measures divisibility, and it is used throughout because the paper's quantities are rationals whose numerators and denominators matter prime by prime: $v_\ell(x) > 0$ says that ℓ divides x in $\mathbb{Z}_{(\ell)}$.

Proposition 2.82. *Let p be a prime and $x, y \in \mathbb{Q}$.*

(i) $v_p(xy) = v_p(x) + v_p(y)$.

(ii) $v_p(x+y) \geq \min(v_p(x), v_p(y))$, *with equality if* $v_p(x) \neq v_p(y)$.

(iii) $v_p(x) \geq 0$ *iff* $x \in \mathbb{Z}_{(p)}$, *and* $v_p(x) = 0$ *iff* $x \in \mathbb{Z}_{(p)}^\times$ *(Proposition 2.21).*

(iv) On $\mathbb{Z}$: $p^k \mid n$ *iff* $v_p(n) \geq k$; $v_p(\gcd(m,n)) = \min(v_p(m), v_p(n))$ *and* $v_p(\operatorname{lcm}(m,n)) = \max(v_p(m), v_p(n))$ *(Proposition 2.26).*

(v) For ideals, $v_p(r\mathbb{Z}) = v_p(r)$ *is well defined; the p-part of $n \neq 0$ is $p^{v_p(n)}$; and $v_p(\ell) = 1$ if $p = \ell$, 0 otherwise.*

(vi) (Legendre's formula) $v_p(n!) = \sum_{k \geq 1} \lfloor n/p^k \rfloor$.

Proof. (i) Multiply the representations. (ii) If $x = p^k a/b$, $y = p^{k'} a'/b'$ with $k \leq k'$, then $x + y = p^k(ab' + p^{k'-k} a' b)/(bb')$, whose numerator is an integer and denominator prime to p; if $k < k'$ the numerator is $\equiv ab' \not\equiv 0 \pmod p$. (The cases with x or y zero are trivial.) (iii) is Proposition 2.21(iv). (iv) is Proposition 2.26(iv). (v) $r\mathbb{Z} = r'\mathbb{Z}$ iff $r' = \pm r$. (vi) $v_p(n!) = \sum_{m=1}^n v_p(m) = \sum_{m=1}^n \sum_{k \geq 1} [p^k \mid m]$, and exchanging the sums, $\#\{m \leq n : p^k \mid m\} = \lfloor n/p^k \rfloor$. □

The inequality in (ii) can be strict when the valuations agree: $v_3(\frac{1}{3}) = v_3(\frac{2}{3}) = -1$, but $\frac{1}{3} + \frac{2}{3} = 1$ has $v_3 = 0$. Legendre's formula gives, for instance, $v_3(10!) = 3 + 1 = 4$, and $10! = 3628800 = 2^8 \cdot 3^4 \cdot 5^2 \cdot 7$.

Definition 2.83. The *p-adic absolute value* on $\mathbb{Q}$ is $|x|_p = p^{-v_p(x)}$, $|0|_p = 0$; $|x|_\infty$ is the usual absolute value. An *absolute value* on a field is a function $|\cdot| \colon K \to \mathbb{R}_{\geq 0}$ with $|x| = 0$ iff $x = 0$, $|xy| = |x||y|$, and $|x + y| \leq |x| + |y|$; two are *equivalent* if one is a positive power of the other.

Proposition 2.84. *(i) $|\cdot|_p$ is an absolute value satisfying the ultrametric inequality $|x+y|_p \leq \max(|x|_p, |y|_p)$; $d_p(x,y) = |x-y|_p$ is a metric on $\mathbb{Q}$, in which $p^k \to 0$.*

(ii) (Product formula) $\prod_{p \leq \infty} |x|_p = 1$ *for $x \in \mathbb{Q}^\times$ (the product over all primes and ∞, almost all factors being 1).*

(iii) $\mathbb{Q}$ *is not complete for d_p.*

Proof. (i) is Proposition 2.82(i), (ii); the ultrametric inequality implies the triangle inequality, and $|p^k|_p = p^{-k}$. (ii) Write $x = \pm \prod_p p^{v_p(x)}$ (Proposition 2.26(iii) applied to numerator and denominator); then $|x|_\infty = \prod_p p^{v_p(x)}$ and $\prod_p |x|_p = \prod_p p^{-v_p(x)}$, the inverse. For instance, for $x = -\frac{12}{5}$: $|x|_\infty = \frac{12}{5}$, $|x|_2 = \frac{1}{4}$, $|x|_3 = \frac{1}{3}$, $|x|_5 = 5$, and the product is $\frac{12}{5} \cdot \frac{1}{12} \cdot 5 = 1$. (iii) Choose m and c as follows: for odd p, $m = 2$ and $c = 1 + 2p$, which is not a square (if $1 + 2p = s^2$ then $2p = (s-1)(s+1)$ with both factors even, so $4 \mid 2p$); for $p = 2$, $m = 3$ and $c = 3$, not a cube (a

rational cube root of an integer is an integer, Theorem 2.32(iv), and $1 < 3 < 8$). In both cases $c \equiv 1 \pmod p$ and $p \nmid m$. Starting from $x_1 = 1$, define integers $x_k \equiv 1 \pmod p$ with $x_k^m \equiv c \pmod{p^k}$: given x_k, choose $t \in \mathbb{Z}$ with $m x_k^{m-1} t \equiv (c - x_k^m)/p^k \pmod p$ (possible as $m x_k^{m-1} \not\equiv 0 \pmod p$) and put $x_{k+1} = x_k + t p^k$; the binomial expansion gives $x_{k+1}^m \equiv x_k^m + m x_k^{m-1} t p^k \equiv c \pmod{p^{k+1}}$. Then $|x_{k+1} - x_k|_p \le p^{-k}$, so (x_k) is Cauchy by the ultrametric inequality. If $x_k \to x \in \mathbb{Q}$, then $|x_k^m - x^m|_p \le |x_k - x|_p \max(1, |x|_p)^{m-1} \to 0$ and $|x_k^m - c|_p \le p^{-k} \to 0$, so $x^m = c$, a contradiction. (The completion $\mathbb{Q}_p$ contains the limit; Chapter 7.) □

Theorem 2.85 (Ostrowski)**.** *Every nontrivial absolute value on $\mathbb{Q}$ is equivalent to $|\cdot|_\infty$ or to $|\cdot|_p$ for exactly one prime p.*

We do not prove this; see [142, Chapter II, Section 3]. It is not used in the paper; it explains why the places of $\mathbb{Q}$ are the primes and ∞.

Lemma 2.86. *Let $q \neq \ell$ be primes.*

(i) $v_\ell(q^k) = 0$ *for all $k \in \mathbb{Z}$: q is a unit of $\mathbb{Z}_{(\ell)}$ (an "ℓ-adic unit").*

(ii) For $P \in \mathbb{Z}[X]$ of degree at most d and $k \ge 0$, $P(q^{-k}) \in \mathbb{Z}_{(\ell)}$, and $v_\ell(P(q^{-k})) = v_\ell(q^{kd} P(q^{-k}))$ is the valuation of the integer $q^{kd}P(q^{-k})$; it is finite iff $P(q^{-k}) \neq 0$.

(iii) For $a \in \mathbb{Z}$ and either choice of sign:

$$v_\ell\Big(\frac{q-1}{q}\Big) = v_\ell(q-1), \qquad v_\ell(1 \mp q^{-1}) = v_\ell(q \mp 1),$$
$$v_\ell(1 - q^{-2}) = v_\ell(q^2 - 1) = v_\ell(q-1) + v_\ell(q+1),$$
$$v_\ell\Big(\frac{q-1}{q} \cdot \frac{(q+1)^2 - a^2}{q^2}\Big) = v_\ell(q-1) + v_\ell((q+1)^2 - a^2) \quad \text{when } (q+1)^2 \neq a^2.$$

All these valuations are ≥ 0.

(iv) For $q = 2$, $\ell = 3$: $v_3(1 + 2 \cdot 2^{-2}) = v_3(3/2) = 1$.

Proof. (i) $v_\ell(q) = 0$ and Proposition 2.82(i). (ii) $q^{kd}P(q^{-k}) = \sum_i a_i q^{k(d-i)} \in \mathbb{Z}$ for $P = \sum_{i \le d} a_i X^i$, and $v_\ell(q^{-kd}) = 0$. (iii) Each rational is an integer divided by a power of q; apply (i), Proposition 2.82(i) and Lemma 2.42(v). (iv) $1 + \frac12 = \frac32$. □

Proposition 2.87 (the I_0^* identity)**.** *Let $q \neq 0$ and a be complex numbers and α, β the roots of $X^2 - aX + q$, so $\alpha + \beta = a$ and $\alpha\beta = q$. Then*

$$\Big(1 - \frac{\alpha}{\beta q}\Big)\Big(1 - \frac{1}{q}\Big)\Big(1 - \frac{\beta}{\alpha q}\Big) = \frac{q-1}{q} \cdot \frac{(q+1)^2 - a^2}{q^2},$$

and $(q+1)^2 - a^2 = (q+1-a)(q+1+a)$. Equivalently, $(1 - qX)(1 - (a^2 - 2q)X + q^2X^2)$ at $X = q^{-2}$ equals the right side. If $q > 0$ and a is real with $a^2 \le 4q$, then $(q+1)^2 - a^2 \ge (q-1)^2$, which is > 0 for $q \neq 1$.

Proof. $\frac{\alpha}{\beta} + \frac{\beta}{\alpha} = \frac{(\alpha+\beta)^2 - 2\alpha\beta}{\alpha\beta} = \frac{a^2 - 2q}{q}$ and $\frac{\alpha}{\beta} \cdot \frac{\beta}{\alpha} = 1$, so

$$\Big(1 - \frac{\alpha}{\beta q}\Big)\Big(1 - \frac{\beta}{\alpha q}\Big) = 1 - \frac{a^2 - 2q}{q^2} + \frac{1}{q^2} = \frac{q^2 + 2q + 1 - a^2}{q^2} = \frac{(q+1)^2 - a^2}{q^2}.$$

Multiply by $1 - \frac1q = \frac{q-1}{q}$. The polynomial form: $1 - (a^2 - 2q)q^{-2} + q^2 q^{-4}$ is the same middle factor, and $1 - q \cdot q^{-2} = 1 - q^{-1}$. Finally $(q+1)^2 - a^2 \ge (q+1)^2 - 4q = (q-1)^2$. □

For an elliptic curve E' over $\mathbb{F}_q$ with $a = q+1-\#E'(\mathbb{F}_q)$ and $|a| \le 2\sqrt{q}$ (Hasse's bound, Chapter 9), the two factors $q+1-a$ and $q+1+a$ are $\#E'(\mathbb{F}_q)$ and the number of points of its quadratic twist over $\mathbb{F}_q$; so $(q+1)^2 - a^2$ is a nonzero integer, and the last valuation in Lemma 2.86(iii) is finite.

Proposition 2.88 (the paper's local terms)**.** *Let $q \ge 5$ be a prime, $\ell \ne q$ an odd prime, and $a \in \mathbb{Z}$ with $a^2 \le 4q$. Put*

$$e_{\mathrm{II}} = v_\ell(q - \chi_{-3}(q)), \qquad e_{\mathrm{III}} = v_\ell(q - \chi_{-4}(q)),$$
$$e_{\mathrm{I}^*} = v_\ell(q^2-1), \qquad e_{\mathrm{I}_0^*}(a) = v_\ell(q-1) + v_\ell((q+1)^2 - a^2).$$

These are finite nonnegative integers, equal to the valuations of $1-\chi_{-3}(q)q^{-1}$, $1-\chi_{-4}(q)q^{-1}$, $1-q^{-2}$ and of the product in Proposition 2.87, and:

(i) $e_{\mathrm{II}} = v_\ell(q-1)$ *if* $q \equiv 1 \pmod 3$ *and* $v_\ell(q+1)$ *if* $q \equiv 2 \pmod 3$. *For* $\ell = 3$, $e_{\mathrm{II}} \ge 1$ *always, and it is unbounded ($q = 53$: $v_3(54) = 3$; $q = 163$: $v_3(162) = 4$; these are the least primes with $e_{\mathrm{II}} \ge 3$, resp. ≥ 4). For $\ell \ge 5$, $e_{\mathrm{II}} \ge 1$ iff $q \equiv \chi_{-3}(q) \pmod \ell$.*

(ii) For $\ell = 3$, $e_{\mathrm{III}} \ge 1$ iff $q \equiv \pm 1 \pmod{12}$; for $\ell \ge 5$, iff $q \equiv \chi_{-4}(q) \pmod \ell$.

(iii) For $\ell = 3$, $e_{\mathrm{I}^*} \ge 1$ always; for $\ell \ge 5$, $e_{\mathrm{I}^*} \ge 1$ iff $q \equiv \pm 1 \pmod \ell$.

(iv) For $\ell = 3$, $e_{\mathrm{I}_0^*}(a) \ge 1$ iff $q \equiv 1 \pmod 3$ or $3 \mid a$; for $\ell \ge 5$, iff $q \equiv 1 \pmod \ell$ or $a \equiv \pm(q+1) \pmod \ell$.

(v) (Type I_n.) For $n \ge 1$ and $\bar{u} \in \mathbb{F}_q^\times$, the Tamagawa refinement $v_\ell(n) + \min(v_\ell(n), v_\ell(q-1), v_\ell(c(\bar{u})))$ of Lemma lem:tamfactor exceeds $t = v_\ell(n)$ iff $\ell \mid n$, $q \equiv 1 \pmod \ell$ and $\bar{u} \in (\mathbb{F}_q^\times)^\ell$.

Proof. Finiteness: $q - \chi(q) \ge q - 1 > 0$, $q^2 - 1 > 0$, and $(q+1)^2 - a^2 \ge (q-1)^2 > 0$ by Proposition 2.87. The identification with valuations of rationals is Lemma 2.86(iii). (i) By Proposition 2.78, $\chi_{-3}(q) = 1$ iff $q \equiv 1 \pmod 3$, and $q \equiv \chi_{-3}(q) \pmod 3$. The least primes: $e_{\mathrm{II}} \ge 3$ means $q \equiv \pm 1 \pmod{27}$, and the candidates $26, 28, 53$ give the prime 53 (and $53 \equiv 2 \pmod 3$, so $e_{\mathrm{II}} = v_3(54) = 3$); $e_{\mathrm{II}} \ge 4$ means $q \equiv \pm 1 \pmod{81}$, and $80, 82, 161 = 7 \cdot 23$ are not prime, while 163 is, with $163 \equiv 1 \pmod 3$. (ii) Proposition 2.78(iv), and the definition for $\ell \ge 5$. (iii) $q^2 \equiv 1 \pmod 3$ for $q \ne 3$; for $\ell \ge 5$, $\ell \mid (q-1)(q+1)$ iff ℓ divides a factor. (iv) $e_{\mathrm{I}_0^*}(a) \ge 1$ iff $\ell \mid q-1$ or $\ell \mid (q+1-a)(q+1+a)$. For $\ell = 3$ and $q \equiv 2 \pmod 3$, $q+1 \equiv 0$, so the second condition is $3 \mid a^2$. (v) is Proposition 2.53(iv). (Parts (i) to (iii) were also checked for all primes $5 \le q < 10^5$.) □

Example 2.89 (the paper's numbers)**.** The curve data below (Kodaira types, modular degrees, Euler factors at 2) were recomputed with PARI and Cremona's tables; the arithmetic is that of this section.

(a) `121a1`, type II at 11: $\chi_{-3}(11) = -1$, so $e_3 = v_3(11+1) = v_3(12) = 1$; $\deg \varphi_E = 6$ and $v_3(6) = 1$: the bound is attained (Example ex:qual(b)).

(b) `539c1`, type I_3^* at 7 (and I_2 at 11): $e_3 = v_3(7^2-1) = v_3(48) = 1$, $t_3 = v_3(3) = 1$; $\deg \varphi_E = 288 = 2^5 \cdot 3^2$, and $v_3 = 2 = e_3 + t_3$.

(c) `980i1`, type I_5^* at 7, $\ell = 5$: $e_5 = v_5(48) = 0$, $t_5 = v_5(5) = 1$; $\deg \varphi_E = 2880 = 2^6 \cdot 3^2 \cdot 5$. (Here $5 \mid N$, so the example illustrates the congruence, not the theorem.)

(d) `726a1`, type III at 11: $\chi_{-4}(11) = -1$ and $e_3 = v_3(12) = 1$; $11 \equiv 11 \pmod{12}$, as Proposition 2.78(iv) requires.

(e) At $q = 2$ the Kodaira type does not determine P_2, and $e_3 = v_3(P_2(\frac{1}{4}))$ (the denominator $1 - a_2^2/4$ is 1, as $a_2 = 0$ at an additive prime). `52a1` (type IV* at 2) and `336f1` (type II at 2) have $P_2 = 1 + 2X$, so $e_3 = v_3(\frac{3}{2}) = 1$; $\deg \varphi_E = 3$, resp. 24. `123211` (type II* at 2) has $P_2 = 1 + 2X - 4X^2 - 8X^3 = (1 - 2X)(1 + 2X)^2$, so $P_2(\frac{1}{4}) = \frac{1}{2} \cdot \frac{9}{4} = \frac{9}{8}$ and $e_3 = 2$, with $\deg \varphi_E = 288$; and `592c1` (type II* at 2) has $P_2 = (1 - 2X)(1 + 4X^2)$, $P_2(\frac{1}{4}) = \frac{5}{8}$, $e_5 = 1$, $\deg \varphi_E = 80$. The two cubic factors are the polynomial of Proposition 2.87 with $q = 2$ and $a = 0$, resp. $a = -2$: $\frac{1}{2} \cdot \frac{9 - a^2}{4}$ is $\frac{9}{8}$, resp. $\frac{5}{8}$.

(f) `539d1`, type I_0^* at 7; its twist by χ_{-7} is $E' =$ `11a3`, with good reduction at 7 and $a_7(E') = -2$ (so $\#E'(\mathbb{F}_7) = 10$). Then $e_3 = v_3(6) + v_3(64 - 4) = 1 + 1 = 2$, and $\deg \varphi_E = 72 = 2^3 \cdot 3^2$.

(g) `11a1` has type I_5 at 11 and $e_3 = 0$ there; its twist by χ_{-11} is `121d2`, of type I_5^* at 11, with $e_3 = v_3(11^2 - 1) = v_3(120) = 1$. So $e_\ell(E, q)$ is not invariant under a quadratic twist ramified at q, as Definition def:terms says.

In the paper 2.90. Definition def:terms sets

$$e_\ell(E, q) = v_\ell(L_q(A_f, 1)^{-1} / L_q^{\mathrm{nv}}(A_f, 1)^{-1}) = v_\ell(P_q(q^{-2})/(1 - a_q(E)^2 q^{-2})).$$

By Lemma 2.86(ii) both numerator and denominator lie in $\mathbb{Z}_{(\ell)}$, and the valuation of the quotient is the difference of their valuations. At a multiplicative prime $a_q^2 = 1$ and $P_q(X) = 1 - X$, so the quotient is 1 and $e_\ell = 0$; at an additive prime $a_q = 0$ and the denominator is 1. The proof of Lemma lem:euler then reads "$e_\ell = v_\ell(1 - q^{-2}) = v_\ell(q^2 - 1)$" (type I_n^*) and "$e_\ell = v_\ell(1 - \chi_{-3}(q)q^{-1}) = v_\ell(q - \chi_{-3}(q))$" (types II to IV*): Lemma 2.86(iii); its displayed identity for type I_0^* is Proposition 2.87, and the same polynomial is shape (ii) of Proposition prop:shapes. Remark rem:wild ("$P_2(X) = 1 + 2X$ and $e_3 = 1$") is Lemma 2.86(iv). Remark rem:afterquant(1) and the abstract's description of the terms rest on Proposition 2.88: under the hypotheses of Theorem thm:quant ($3 \nmid 2N$, $E[3]$ irreducible) a single prime of type I_n^* forces $3 \mid \deg \varphi_E$, because $e_3 = v_3(q^2 - 1) \geq 1$ for every $q \geq 5$, and so does a prime of type I_0^* with $q \equiv 1 \pmod 3$, because then $v_3(q - 1) \geq 1$. That the table is right, i.e. that these expressions are the $e_\ell(E, q)$, is Lemma lem:euler, proved in Chapters 19 and 21.

2.12 Exercises

Exercise 2.91 (a toy Hecke algebra)**.** Let $r \geq 1$ and $R = \{(a, b) \in \mathbb{Z}^2 : a \equiv b \pmod r\}$, a subring of $\mathbb{Z} \times \mathbb{Z}$; let $\phi(a, b) = a$, $I = \ker \phi$ and $J = \{(a, 0) \in R\}$. Show that $I \cap J = 0$, that $R/(I + J) \simeq \mathbb{Z}/\phi(J) = \mathbb{Z}/r$, and that the cokernel of $R \to R/I \times R/J$ is $\mathbb{Z}/r$ (Theorem 2.12 and Proposition 2.13). Interpret R as the Hecke algebra of two "eigenforms" whose eigenvalues are congruent modulo r, and r as their congruence number, as in Lemma lem:crit.

Exercise 2.92. Show that a ring homomorphism $\mathbb{Z}/r\mathbb{Z} \to k$, k a field of characteristic ℓ, exists iff $\ell \mid r$. Deduce the last step of Lemma lem:crit: if $I + J$ is contained in a maximal ideal of $\mathbb{T}$ of residue characteristic ℓ, then ℓ divides $\#\mathbb{T}/(I + J)$ (Proposition 2.18).

Exercise 2.93. In $\mathbb{Z}[\zeta_3]$, check $5+\zeta_3 = (2-\zeta_3)(2+\zeta_3)$ and $7 = (3+\zeta_3)(2-\zeta_3)$ (note $3+\zeta_3^2 = 2-\zeta_3$), and compute $\gcd(7, 5+\zeta_3)$ by the Euclidean algorithm (answer: $2-\zeta_3$, of norm 7, up to units). Verify by listing the solutions of $a^2-ab+b^2=1$ that $\mathbb{Z}[\zeta_3]^\times = \mu_6$.

Exercise 2.94. Check the values in Example ex:qual of the paper: $e_3(\texttt{121a1}, 11) = v_3(12) = 1$; $e_3(\texttt{539c1}, 7) = v_3(48) = 1$ and $t_3(\texttt{539c1}, 7) = 1$; $e_5(\texttt{980i1}, 7) = 0$ and $t_5(\texttt{980i1}, 7) = 1$. Compare with $v_3(6)$, $v_3(2^5\cdot 3^2)$ and $v_5(2^6\cdot 3^2\cdot 5)$ (Example 2.89).

Exercise 2.95. Check the claim in the proof of Proposition prop:forms that $q \equiv \chi_{-3}(q) \pmod 3$ for every prime $q \neq 3$, so that $e_3(E,q) \geq 1$ at every prime $q \geq 5$ of type II, II*, IV, IV*. Find the least prime q with $v_3(q-\chi_{-3}(q)) \geq 3$ and with $v_3(q-\chi_{-3}(q)) \geq 4$ (answers 53 and 163).

Exercise 2.96. Check the statement of Section sec:anomaly that the type III primes $q \geq 5$ with $e_3 > 0$ are those with $q \equiv 1$ or $11 \pmod{12}$. For $\ell = 5$, show that the type III primes with $e_5 > 0$ are those with $q \equiv \pm 1 \pmod{20}$.

Exercise 2.97. Prove Proposition 2.87 by expanding the product. Then check part (1) of Remark rem:afterquant: every prime $q \geq 5$ of type I_n^* has $e_3 \geq 1$, and a prime of type I_0^* has $e_3 \geq 1$ iff $q \equiv 1 \pmod 3$ or $3 \mid a_q(E')$. Compute e_3 for type I_0^* at $q=7$ with $a_7(E') = -2$, and at $q=5$ and at $q=11$ with $a_q(E') = 0$ (answers: 2, 2, 2).

Exercise 2.98. Check Remark rem:wild: with $P_2(X) = 1+2X$, $e_3 = v_3(P_2(1/4)) = 1$; with $P_2 = 1$, $e_3 = 0$. Explain why the denominator $1-a_q^2 q^{-2}$ of Definition def:terms is 1 at an additive prime and $1-q^{-2} = P_q(q^{-2})$ at a multiplicative one, so that $e_\ell = 0$ there.

Exercise 2.99. For $q = 7, 13, 19, 37$ and $\ell = 3$, list the cubes and the ninth powers in $\mathbb{F}_q^\times$, and compute $v_3(c(u))$ for $u = 2, 3, -1$ (answers: $0,0,1$ for $q=7$ and 13; $0,0,2$ for $q=19$ and 37). Check the statement of Lemma lem:tamfactor that $\min(v_\ell(n), v_\ell(q-1), v_\ell(c)) > 0$ iff $q \equiv 1 \pmod \ell$, $\ell \mid n$ and u is an ℓ-th power.

Exercise 2.100. Prove Theorem 2.52(iii) directly from a generator of $\mathbb{F}_q^\times$, without quoting Chapter 1. Show that the ℓ-th power map of $\mathbb{F}_q^\times$ is bijective iff $q \not\equiv 1 \pmod \ell$. Find the least f with $\mu_9 \subset \mathbb{F}_{2^f}$ (answer 6) and show $v_3(2^{6m}-1) = 2 + v_3(m)$ (Lemma 2.42).

Exercise 2.101. Show that the only solutions of $a^2 \equiv 1 \pmod{\ell^k}$ (ℓ odd) are $a \equiv \pm 1$, and deduce that a homomorphism χ onto $(\mathbb{Z}/\ell^k)^\times$ with $\chi^2 = 1$ forces $\ell^k = 3$. Explain how this gives $h_\ell(E) = 0$ for $\ell \geq 5$ and $h_3(E) \leq 1$ in Lemma lem:h0 (the Galois side is Chapter 5).

Exercise 2.102. Construct $\mathbb{F}_{16} = \mathbb{F}_2[x]/(x^4+x+1)$ (check irreducibility: no root, and $x^4+x+1 \neq (x^2+x+1)^2$, the only irreducible quadratic being x^2+x+1). Show that $\bar{x}$ generates $\mathbb{F}_{16}^\times$ ($\bar{x}^3 \neq 1$ and $\bar{x}^5 = \bar{x}^2+\bar{x} \neq 1$). List the subfields, and show that the Frobenius has orbits of sizes $1,1,2,4,4,4$ on $\mathbb{F}_{16}$; deduce $N_4 = 3$ over $\mathbb{F}_2$.

Exercise 2.103 (Eisenstein's proof of reciprocity)**.** Let $p \neq q$ be odd primes. Prove Eisenstein's lemma $\left(\frac{q}{p}\right) = (-1)^{\sum_{a=1}^{(p-1)/2} \lfloor 2qa/p \rfloor}$ and show that the exponent has the parity of $\sum_{u=1}^{(p-1)/2} \lfloor qu/p \rfloor$. By counting the lattice points in the rectangle $0 < x < p/2$, $0 < y < q/2$ on either side of the diagonal, show $\sum_{u=1}^{(p-1)/2} \lfloor qu/p \rfloor + \sum_{v=1}^{(q-1)/2} \lfloor pv/q \rfloor = \frac{p-1}{2}\cdot\frac{q-1}{2}$, and deduce Theorem 2.64(i). (Both identities were checked for all odd primes below 200.)

Exercise 2.104. Verify that $\left(\frac{D}{\cdot}\right)$ is periodic modulo $|D|$ for $D = -3, -4, -7, 5, 8, 12$. Tabulate $\chi_{-3}, \chi_{-4}, \chi_{-7}, \chi_{-11}, \chi_5$ at the primes below 30. Show that on integers prime to 6 the function $\left(\frac{3}{\cdot}\right)$ agrees with χ_{12}, of conductor 12, while $\left(\frac{-3}{\cdot}\right) = \chi_{-3}$ has conductor 3: the sign in q^* matters.

Exercise 2.105. Compute $\tau(\chi_{-4}) = 2i$, $\tau(\chi_{-3}) = \sqrt{-3}$ and $\tau((\frac{\cdot}{5})) = \sqrt{5}$ (use $\cos(2\pi/5) = (\sqrt{5}-1)/4$). Show that χ_{-3} regarded modulo 6 has Gauss sum $\sqrt{-3}$ and that the principal character modulo n has $\tau(\chi_0) = \mu(n)$.

Exercise 2.106. Show that x^4+1 is irreducible over $\mathbb{Q}$ but reducible modulo every prime (Warning 2.35). Check the claim of Proposition prop:ns for `11a1`, whose mod 3 image is $\mathrm{GL}_2(\mathbb{F}_3)$: its 3-division polynomial $3x^4 - 4x^3 - 60x^2 - 237x - 21$ is irreducible (Example 2.36).

Exercise 2.107. Show that if $p \nmid n$ and $p \mid \Phi_n(a)$, then $p \equiv 1 \pmod{n}$, and deduce that there are infinitely many primes $\equiv 1 \pmod{n}$ (Proposition 2.59). Check with $\Phi_{12}(2) = 13$ and $\Phi_9(2) = 73$.

2.13 Notes and references

Sections 1 to 4, 6 and 8 follow Dummit and Foote [58]: Sections 7.1 to 7.6 (rings, ideals, quotients, fractions, the Chinese remainder theorem), 8.1 to 8.3 (Euclidean domains, PIDs, UFDs), 9.1 to 9.5 (polynomial rings, Gauss's lemma, Eisenstein's criterion), 13.1, 13.4 to 13.6 (field extensions, splitting fields, separability, cyclotomic polynomials) and 14.3 (finite fields); Lang [109, Chapter IV, Section 2, and Chapter V, Section 5] gives Gauss's lemma and finite fields in greater generality, and Atiyah and Macdonald [7, Chapter 1] the existence of maximal ideals and the ideal theory of products. The Gaussian and Eisenstein integers are treated in Ireland and Rosen [87, Chapter 1], together with unique factorisation in $\mathbb{Z}$.

Sections 5 to 10 are classical elementary number theory: Ireland and Rosen [87], Chapter 4 for $(\mathbb{Z}/n)^\times$ and primitive roots, Chapter 5 for quadratic reciprocity and the Jacobi symbol, Chapter 6 for the quadratic Gauss sum (Section 6.4 for Gauss's determination of its sign, Remark 2.63), Chapter 7 for finite fields, Chapter 8 for Gauss sums of general characters; Serre [172, Chapter I] proves reciprocity by the same computation in characteristic p as Theorem 2.64 and the second supplement with an eighth root of unity. Among the many other proofs of reciprocity, Eisenstein's lattice-point proof is Exercise 2.103, and the proof through the splitting of p in $\mathbb{Q}(\zeta_q)$ is given in Chapter 6. The lifting-the-exponent lemma is folklore; the form used here, with its proof by the binomial theorem, is the standard one in the proof that $(\mathbb{Z}/p^k)^\times$ is cyclic.

The Kronecker symbol follows Cohen [30, Section 1.4], and fundamental discriminants Cohen [30, Section 5.1]; Dirichlet characters, conductors and primitivity follow Washington [201, Chapter 3], and orthogonality is Serre [172, Chapter VI, Section 1]. The formula for the Gauss sum of an imprimitive character (Theorem 2.77(iv)) is proved here by the Chinese remainder theorem and the Ramanujan sum $\sum_{(y,m)=1} \zeta_m^y = \mu(m)$. Dirichlet characters as characters of $G_{\mathbb{Q}}$ are Chapter 6, twisting of modular forms by them Chapter 13.

Valuations and the p-adic absolute value are in Serre [172, Chapter II] and Neukirch [142, Chapter II], where Ostrowski's theorem (Theorem 2.85) is proved in Section 3. The arithmetic of the paper's local terms (Lemma 2.86 and Propositions 2.87 and 2.88) is elementary; the identification of these expressions with the Euler factors of the adjoint L-function is Lemma lem:euler of the paper, treated in Chapters 19 and 21. Curve data were computed with PARI/GP [148] and Cremona's tables [35].

The following are proved in full here although a statement with a reference would have sufficed: the existence of maximal ideals (from Zorn's lemma), the unique factorisation of $R[x]$ over a UFD, the primitivity of χ_D for fundamental D (Corollary 2.76) and the Gauss sum of an imprimitive character. Only Ostrowski's theorem and the sign of the quadratic Gauss sum are stated without proof, and neither is used. No theorem numbers of the sources are cited. The

chapter and section numbers above are given as pointers to the relevant part of each book; they were not verified against the printed editions.

Chapter 3

Modules and commutative algebra

The paper's arithmetic is carried by modules: Selmer groups and Tamagawa factors are finite $\mathbb{Z}_\ell$-modules measured by length and by Fitting ideals; the Hecke algebra $\mathbb{T}$ is a finite free $\mathbb{Z}$-algebra whose completion $\mathbb{T}\otimes\mathbb{Z}_\ell$ splits into local factors $\mathbb{T}_\mathfrak{m}$; the cohomology $H^1(X_0(N),\mathbb{Z}_\ell)$ is a lattice with a perfect alternating pairing for which $\mathbb{T}$ is self-adjoint; and the inequality of Lemma lem:ddt417 compares a Gram determinant with a congruence ideal. This chapter develops, with complete proofs except where a reference is given, the commutative algebra behind all of this: exact sequences and the snake lemma, Hom and $\otimes$, Nakayama's lemma and localisation, modules over principal ideal domains and saturation, discrete valuation rings and $\mathbb{Z}_\ell$, length (with the Jordan-Holder theorem) and Fitting ideals, Pontryagin duality, pairings and Gram determinants, finite free algebras over a discrete valuation ring with their idempotents and generalised eigenspaces, congruence ideals and Gorenstein algebras. It uses the ring theory of Chapter 2 and the finite abelian groups of Chapter 1, and does not reprove them.

Core results at a glance

Rings are commutative with 1 (except in item **3.36**); $\mathcal{O}$ is a discrete valuation ring with uniformiser ϖ, residue field k, fraction field K and valuation v; $M^\vee=\mathrm{Hom}(M,R)$ is the linear dual and M^* the Pontryagin dual; "length" is $\mathrm{length}_{\mathbb{Z}_\ell}$; $\mathbb{T}_\mathfrak{m}$ is a factor of $\mathbb{T}\otimes\mathbb{Z}_\ell$.

3.1 Conventions. Appendix B (B-C4, B-C10, B-C13, B-C15); rings commutative; $\mathcal{O}$, ϖ, k, K, v with $v(\varpi)=1$; $M[\mathfrak{a}]$; lattices; pairings, left and right orthogonals, self-adjointness; lengths in place of the order $\#\mathcal{O}/\Delta$; relations are rows; the letters I, J of Lemma lem:crit; $\mathbb{T}_\mathfrak{m}=e_\mathfrak{m}(\mathbb{T}\otimes\mathbb{Z}_\ell)$, never the algebraic localisation $\mathbb{T}_{(\mathfrak{m})}$. Conventions 3.1 and 3.2.

3.2 Modules (definition: module, submodule, quotient, finitely generated, cyclic, homomorphism, kernel, image, cokernel, Hom_R, End_R; action of an algebra, faithful action). Definitions 3.3 and 3.6.

3.3 Basic facts. The set $\mathrm{Hom}_R(M,N)$ is an R-module, the ring $\mathrm{End}_R(M)$ is an R-algebra, and $Rm\simeq R/\operatorname{Ann}_R(m)$ for $m\in M$. *(proved here)* Proposition 3.4.

3.4 Isomorphism theorems. $M/\ker f\simeq f(M)$; $(A+B)/B\simeq A/(A\cap B)$; $(M/B)/(A/B)\simeq M/A$ with the correspondence of submodules; for f surjective with kernel K_0, $M/(K_0+A)\simeq N/f(A)$. *(proved here)* Theorem 3.8.

3.5 Exact sequences; splitting lemma (definition: exactness, short exact sequences). For $0 \to M' \to M \to M'' \to 0$: a section of $M \to M''$ exists iff a retraction of $M' \to M$ exists iff $M \simeq M' \oplus M''$ compatibly. *(proved here)* Definition 3.10, Lemma 3.11.

3.6 Two submodules. $0 \to M/(A \cap B) \to M/A \oplus M/B \to M/(A+B) \to 0$ is exact; $A + B$ is direct iff $A \cap B = 0$. *(proved here)* Proposition 3.13.

3.7 Snake lemma. A commutative diagram with exact rows $M' \to M \to M'' \to 0$ and $0 \to N' \to N \to N''$ gives an exact sequence $\ker f' \to \ker f \to \ker f'' \xrightarrow{\delta} \operatorname{coker} f' \to \operatorname{coker} f \to \operatorname{coker} f''$, with $0 \to$ at the left if $M' \to M$ is injective and $\to 0$ at the right if $N \to N''$ is surjective. *(proved here)* Lemma 3.15.

3.8 Multiplication by n. For $0 \to A \to B \to C \to 0$: $0 \to A[n] \to B[n] \to C[n] \to A/n \to B/n \to C/n \to 0$ is exact; $\#\ker\phi = \#\operatorname{coker}\phi$ for an endomorphism of a finite abelian group. *(proved here)* Corollary 3.16.

3.9 Five lemma. In a commutative ladder of exact rows of five terms, if the four outer maps are isomorphisms so is the middle one (with the two one-sided halves). *(proved here)* Lemma 3.17.

3.10 Sums and products. Hom turns direct sums in the first variable, and products in the second, into products; $M = A \oplus B$ iff $A + B = M$ and $A \cap B = 0$ iff $A = eM$, $B = (1-e)M$ for an idempotent $e \in \operatorname{End} M$. *(proved here)* Definition 3.18, Proposition 3.19.

3.11 Free modules. Universal property; every module has a presentation $F_1 \to F_0 \to M \to 0$; $R^m \simeq R^n$ implies $m = n$ $(R \neq 0)$; $A \in \mathrm{M}_n(R)$ is invertible iff $\det A \in R^\times$. *(proved here)* Definition 3.20, Proposition 3.21.

3.12 Projective modules. Equivalent: every surjection onto P splits; P is a summand of a free module; $\mathrm{Hom}(P, -)$ is exact; maps from P lift along surjections. eR is projective for an idempotent e; $\mathbb{Z}/2$ over $\mathbb{Z}/6$ is projective, not free. *(proved here)* Definition 3.22, Proposition 3.23.

3.13 Hom. $\mathrm{Hom}(R/\mathfrak{a}, M) = M[\mathfrak{a}]$; $\mathrm{Hom}(N, -)$ and $\mathrm{Hom}(-, N)$ are left exact, not right exact; $M \simeq M^{\vee\vee}$ for M free of finite rank; over a domain $M^\vee$ is torsion-free. *(proved here)* Proposition 3.25.

3.14 Tensor product. Existence and universal property; $(R/\mathfrak{a}) \otimes M = M/\mathfrak{a}M$; distributivity; adjunction $\mathrm{Hom}(M \otimes N, P) \simeq \mathrm{Hom}(M, \mathrm{Hom}(N, P))$; base change $S \otimes_R M$. Examples: $\mathbb{Z}/m \otimes \mathbb{Z}/n = \mathbb{Z}/\gcd(m,n)$, $\mathbb{Z}_\ell \otimes \mathbb{Z}/n = \mathbb{Z}/\ell^{v_\ell(n)}$, $\mathbb{Q}_\ell/\mathbb{Z}_\ell \otimes A = 0$ for A torsion. *(proved here)* Theorem 3.26, Example 3.27.

3.15 Right exactness. $- \otimes N$ is right exact and not left exact; N is flat if $- \otimes N$ is exact; projective modules are flat. *(proved here)* Proposition 3.28.

3.16 Flatness. $S^{-1}R$ is flat; over a principal ideal domain flat equals torsion-free (so $\mathbb{Z}_\ell$, $\mathbb{Q}$ are flat over $\mathbb{Z}$); for $R \to S$ flat, $S \otimes -$ commutes with kernels, images, cokernels, finite intersections, $M[\mathfrak{a}]$ ($\mathfrak{a}$ finitely generated) and Ann of finitely generated modules; saturation commutes with flat extensions of principal ideal domains. *(proved here)* Proposition 3.29.

3.17 Noetherian modules. Ascending chain condition, maximal condition, every submodule finitely generated: equivalent; closed under submodules, quotients, extensions; finitely generated modules over Noetherian rings are finitely presented; in a nonzero Noetherian ring every proper ideal lies in a maximal ideal; rings finite over Noetherian rings are Noetherian. Hilbert's basis theorem. *(proved here, except Hilbert's theorem: stated; reference)* Proposition 3.31.

3.18 Determinant trick. If M has n generators and $\phi(M) \subseteq \mathfrak{a}M$, then $\phi^n + a_1\phi^{n-1} + \cdots + a_n = 0$ with $a_i \in \mathfrak{a}^i$; if $\mathfrak{a}M = M$ some $x \equiv 1 \bmod \mathfrak{a}$ kills M; surjective endomorphisms of finitely generated modules are bijective. *(proved here)* Lemma 3.32.

3.19 Local rings. R is local iff its non-units form an ideal $\mathfrak{m}$; $1 + x$ is a unit for x in the Jacobson radical; examples $\mathbb{Z}/p^n$, $k[x]/(x^2)$, $\mathbb{T}_{\mathfrak{m}}$; non-examples $\mathbb{Z}_\ell \times \mathbb{Z}_\ell$, $\mathbb{Z}_{(11)}[x]/(x^2 + x - 1)$. *(proved here)* Definition 3.33, Proposition 3.34.

3.20 Nakayama's lemma. Over a local ring $(R, \mathfrak{m}, k)$ and M finitely generated: $\mathfrak{m}M = M \Rightarrow M = 0$ (also for ideals in the Jacobson radical); $N + \mathfrak{m}M = M \Rightarrow N = M$; x_i generate M iff they span $M/\mathfrak{m}M$, and the minimal number of generators is $\dim_k M/\mathfrak{m}M$; surjectivity and invertibility can be tested modulo $\mathfrak{m}$; finitely generated projective modules are free. *(proved here)* Theorem 3.35.

3.21 Localisation. $S^{-1}R$ has the universal property for inverting S; $S^{-1}M = S^{-1}R \otimes M$ and localisation is exact; primes of $S^{-1}R$ are the primes of R missing S; $R_{\mathfrak{p}}$ is local; $M = 0$ iff all $M_{\mathfrak{m}} = 0$; localisation commutes with sums, quotients and Ann of finitely generated modules (and with Hom out of finitely presented modules: stated); $(\mathbb{Z}/n)_{(p)} = \mathbb{Z}/p^{v_p(n)}$; localising $R_1 \times R_2$ at $\mathfrak{p}_1 \times R_2$ gives $(R_1)_{\mathfrak{p}_1}$. *(proved here, except the statement on* Hom*: stated; reference)* Theorem 3.38.

3.22 Submodules of free modules. Over a principal ideal domain a submodule of R^n is free of rank $\leq n$; finitely generated projective modules are free. *(proved here)* Theorem 3.40.

3.23 Smith normal form. Over a principal ideal domain, $UAV = \operatorname{diag}(d_1, \ldots, d_s, 0, \ldots)$ with $d_1 \mid \cdots \mid d_s$, U, V invertible; $(d_1 \cdots d_k)$ is the ideal of $k \times k$ minors, so the (d_i) are unique. *(proved here)* Theorem 3.41.

3.24 Structure theorem. Over a principal ideal domain, $M \simeq R^r \oplus \bigoplus R/(d_i)$ ($d_1 \mid \cdots \mid d_s$ non-units) $\simeq R^r \oplus \bigoplus R/(p_j^{a_j})$, with r, the (d_i) and the multiset of $(p_j^{a_j})$ unique. *(proved here)* Theorem 3.43.

3.25 Torsion. $M_{\mathrm{tor}} = \ker(M \to M \otimes K)$; over a principal ideal domain finitely generated torsion-free modules are free and $M \simeq M_{\mathrm{tor}} \oplus M/M_{\mathrm{tor}}$; if $R \subseteq R'$ with R' a principal ideal domain free of rank e over R, a finitely generated R'-module that is torsion-free of R-rank n is R'-free of rank n/e (so T_3E is free of rank one over $\mathbb{Z}_3[\zeta_3]$ in Lemma lem:IV). *(proved here)* Definition 3.45, Proposition 3.46.

3.26 Saturation. For L in a lattice M over a principal ideal domain: M/L torsion-free iff $L = M \cap KL$ iff L is a direct summand iff (over $\mathcal{O}$) $L \cap \varpi M = \varpi L$; $\operatorname{sat}(L) = M \cap KL$ is the least saturated submodule containing L; kernels to torsion-free modules, $M \cap W$, $M[\mathfrak{a}]$ and orthogonals are saturated. *(proved here)* Definition 3.48, Proposition 3.49.

3.27 Stacked bases. For $L \subseteq M \simeq R^n$ of rank d there is a basis e_i of M with $d_1 e_1, \dots, d_d e_d$ a basis of L, $d_1 \mid \cdots \mid d_d$ unique; L is saturated iff all d_i are units; for $d = n$, $[M : L] = |\det B|$ over $\mathbb{Z}$ and $\operatorname{length}(M/L) = v(\det B)$ over $\mathcal{O}$. *(proved here)* Theorem 3.50.

3.28 Dual of an inclusion. For lattices $L \subseteq M$ of the same rank, $M^\vee \hookrightarrow L^\vee$ and $L^\vee/M^\vee \simeq \operatorname{Hom}(M/L, K/R)$, which is $(M/L)^*$ over $\mathbb{Z}$ or $\mathbb{Z}_\ell$; so $[L^\vee : M^\vee] = [M : L]$. *(proved here)* Proposition 3.51.

3.29 Congruence module of a decomposition. If $M \otimes K = V_1 \oplus V_2$ and $L_i = M \cap V_i$, then $M/(L_1 \oplus L_2) \simeq p_1(M)/L_1 \simeq p_2(M)/L_2$; if $V_1 = Kf$ with f primitive, the quotient is cyclic $\simeq R/(r)$, $rh = f + g_0$ with $p_1(h) = f/r$, $g_0 \in L_2$, and $f \equiv g \pmod{r'M}$ for some $g \in L_2$ iff $r' \mid r$. *(proved here)* Proposition 3.53.

3.30 Discrete valuation rings. For a Noetherian local domain $\mathcal{O}$, not a field: $\mathfrak{m}$ principal iff $\mathcal{O}$ is a principal ideal domain iff the nonzero ideals are the $\mathfrak{m}^k$ iff $\mathcal{O}$ is the ring of a discrete valuation iff $\mathcal{O}$ is integrally closed of dimension one; then $x = u\varpi^{v(x)}$ uniquely. $\mathcal{O}$ is *complete* if $\mathcal{O} \to \varprojlim \mathcal{O}/\varpi^n$ is bijective. *(proved here, except the equivalence with integral closure: stated; reference)* Theorem 3.55.

3.31 Modules over a discrete valuation ring. $M \simeq \mathcal{O}^r \oplus \bigoplus_{i \le s} \mathcal{O}/\varpi^{a_i}$ uniquely; torsion-free implies free; $\dim_k M/\varpi M = r + s$, $\dim_k M[\varpi] = s$; formulas for $M[\varpi^k]$, $M/\varpi^k M$; cyclic iff $r + s \le 1$; L saturated iff $L \cap \varpi M = \varpi L$. *(proved here)* Proposition 3.57.

3.32 The ring $\mathbb{Z}_\ell$. $\mathbb{Z}_\ell = \varprojlim \mathbb{Z}/\ell^n$ is a discrete valuation ring with uniformiser ℓ and residue field $\mathbb{F}_\ell$; $\mathbb{Z}_\ell/\ell^n = \mathbb{Z}/\ell^n$; integers prime to ℓ are units, so a $\mathbb{Z}_\ell$-module killed by such an integer is 0; $\mathbb{Q}_\ell = \mathbb{Z}_\ell[1/\ell]$ and $\mathbb{Q} \cap \mathbb{Z}_\ell = \mathbb{Z}_{(\ell)}$; $\mathbb{Z}_\ell$ is flat over $\mathbb{Z}$ and $A \otimes \mathbb{Z}_\ell = \mathbb{Z}_\ell^r \oplus A_{\mathrm{tor}}[\ell^\infty]$; finitely generated $\mathbb{Z}_\ell$-modules are complete; completions of Noetherian rings are flat. *(proved here, except the statement on completions: stated; reference)* Theorem 3.58.

3.33 Baer's criterion. Over a principal ideal domain divisible modules are injective, and $\operatorname{Hom}(-, D)$ is exact. *(proved here)* Lemma 3.59.

3.34 The module $\mathbb{Q}_\ell/\mathbb{Z}_\ell$. $\mathbb{Q}_\ell/\mathbb{Z}_\ell = \mathbb{Z}[1/\ell]/\mathbb{Z} = (\mathbb{Q}/\mathbb{Z})[\ell^\infty] = \varinjlim \mathbb{Z}/\ell^k$; divisible, with $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)[\ell^k] \simeq \mathbb{Z}/\ell^k$ its only proper submodules; $\operatorname{End}_{\mathbb{Z}_\ell}(\mathbb{Q}_\ell/\mathbb{Z}_\ell) = \mathbb{Z}_\ell$; $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ and $\mathbb{Q}/\mathbb{Z}$ are injective. *(proved here)* Proposition 3.60.

3.35 Topology. Finitely generated $\mathbb{Z}_\ell$-modules are compact, Hausdorff and complete; linear maps are continuous, submodules and images closed; $\mathrm{GL}_n(\mathbb{Z}_\ell)$ is profinite; a compact $\mathbb{Z}_\ell$-module A with $A/\ell A$ finite is finitely generated. *(proved here, except topological Nakayama: proof sketched here)* Proposition 3.61.

3.36 Jordan-Holder and length. Over any ring, any two composition series have the same length and factors; submodules and quotients of finite-length modules have finite length; length is additive in exact sequences; finite length iff Noetherian and Artinian (stated). Over a local ring simple modules are $\simeq k$, $\operatorname{length} M = \sum \dim_k \mathfrak{m}^i M/\mathfrak{m}^{i+1} M$ when $\mathfrak{m}^N M = 0$, and finitely generated modules over a Noetherian local ring have finite length iff killed by a power of $\mathfrak{m}$; $\operatorname{length}_R = f \operatorname{length}_{R'}$ for a finite local extension with residue degree f. *(proved here, except "Noetherian and Artinian": stated; reference)* Definition 3.64, Theorem 3.65.

3.37 Length over a discrete valuation ring. $\operatorname{length} \mathcal{O}/\varpi^a = a$; finite length iff torsion; $\#M = (\#k)^{\operatorname{length} M}$ for finite k, so $\operatorname{length}_{\mathbb{Z}_\ell} M = v_\ell(\#M)$; $\operatorname{length} M[\varpi^k] = \operatorname{length} M/\varpi^k M$ for finite length. *(proved here)* Proposition 3.66.

3.38 Annihilators. $\operatorname{Ann}(R/\mathfrak{a}) = \mathfrak{a}$; $\operatorname{Ann}(M \oplus N) = \operatorname{Ann} M \cap \operatorname{Ann} N$; $M[\mathfrak{a}] = \operatorname{Hom}(R/\mathfrak{a}, M)$; $\mathbb{T}[\mathfrak{a}] = \operatorname{Ann}_{\mathbb{T}}(\mathfrak{a})$ and $L[\mathfrak{a}] = \operatorname{Ann}_{\mathbb{T}}(\mathfrak{a})^r$ for $L \simeq \mathbb{T}^r$; flat base change; $\operatorname{Ann}(\bigoplus \mathcal{O}/\varpi^{a_i}) = \varpi^{\max a_i}$. *(proved here)* Definition 3.67, Proposition 3.68.

3.39 Fitting ideals (definition: for generators $x_1, \dots, x_n$, the ideal generated by the determinants of n-tuples of relations, equivalently by the $n \times n$ minors of a presentation matrix; it does not depend on the choices). *(proved here)* Definition 3.69, Lemma 3.70.

3.40 Properties of Fitting ideals. $\operatorname{Fitt}(R/\mathfrak{a}) = \mathfrak{a}$ and $\operatorname{Fitt}(R^n) = 0$; the Fitting ideal of a direct sum is the product, $\operatorname{Fitt}(M \oplus N) = \operatorname{Fitt}(M)\operatorname{Fitt}(N)$; Fitt grows along surjections; for M with n generators, $\operatorname{Ann}(M)^n \subseteq \operatorname{Fitt}(M) \subseteq \operatorname{Ann}(M)$; Fitt commutes with every base change; for a short exact sequence with M' finitely generated, $\operatorname{Fitt}(M')\operatorname{Fitt}(M'') \subseteq \operatorname{Fitt}(M)$, with strict inclusion for the module $\mathbb{Z}[x]/(4, x)$; over a domain, $\operatorname{Fitt}(M) \neq 0$ if and only if M is torsion. *(proved here)* Proposition 3.71.

3.41 Fitting equals ϖ^{length}. Over a principal ideal domain $\operatorname{Fitt}(\bigoplus R/(d_i)) = (\prod d_i)$ (and 0 with a free summand); over $\mathcal{O}$, $\operatorname{Fitt}(M) = \varpi^{\operatorname{length} M}\mathcal{O}$ for torsion M, so $\operatorname{Fitt}_{\mathbb{Z}_\ell}(M) = \#M \cdot \mathbb{Z}_\ell$, multiplicative in exact sequences; $\operatorname{Fitt}_{\mathbb{Z}_\ell}(\mathbb{Z}/\ell^v \oplus \mathbb{Z}/\ell^m) = \ell^{v+m}\mathbb{Z}_\ell$, while $\operatorname{Ann} = \ell^{\max(v,m)}\mathbb{Z}_\ell$. *(proved here)* Theorem 3.72, Example 3.74.

3.42 Pontryagin duality for finite groups. $A^* = \operatorname{Hom}(A, \mathbb{Q}/\mathbb{Z}) \simeq A$; $A \simeq A^{**}$; duality is exact; $B^\perp \simeq (A/B)^*$, $B^* \simeq A^*/B^\perp$; for ℓ-primary A, $A^* = \operatorname{Hom}(A, \mathbb{Q}_\ell/\mathbb{Z}_\ell)$ and $\operatorname{length} A^* = \operatorname{length} A$. *(proved here)* Theorem 3.76.

3.43 Pontryagin duality for $\mathbb{Z}_\ell$-modules. $X^* = \operatorname{Hom}(X, \mathbb{Q}_\ell/\mathbb{Z}_\ell)$ is an exact duality between finitely generated $\mathbb{Z}_\ell$-modules and cofinitely generated ℓ-primary modules, with $\mathbb{Z}_\ell^* = \mathbb{Q}_\ell/\mathbb{Z}_\ell$, $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)^* = \mathbb{Z}_\ell$, $X \simeq X^{**}$, and $W^* = \varprojlim W[\ell^k]^*$ profinite; every cofinitely generated W is $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r \oplus F$ with F finite and $r = \operatorname{rank} W^*$; lengths are preserved. *(proved here; the extension to all compact and discrete modules: stated; reference)* Theorem 3.77.

3.44 T and $W = T \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$. For T free of rank r: $0 \to T \to V \to W \to 0$ is exact; $W \simeq (\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r$; $W[\ell^k] \simeq T/\ell^k T$; $T = \varprojlim W[\ell^k]$; $W^* \simeq T^\vee$; all functorially; the same over any complete $\mathcal{O}$. *(proved here)* Proposition 3.78.

3.45 Cyclic ℓ-primary modules. An ℓ-primary torsion module with $\#A[\ell] \leq \ell$ is 0, $\mathbb{Z}/\ell^h$ or $\mathbb{Q}_\ell/\mathbb{Z}_\ell$; if finite its length is the largest k with an element of exact order ℓ^k. *(proved here)* Corollary 3.79.

3.46 Perfect pairings and Gram determinants. A pairing between free modules of rank n over any ring is perfect iff its Gram determinant is a unit (over a domain, nondegenerate iff it is nonzero); $\det(P^{\mathsf{T}} G Q) = \det P \det Q \det G$, so ΔR, and over $\mathcal{O}$ the valuation $v(\Delta)$, are basis independent; perfectness survives base change. *(proved here)* Definition 3.81, Proposition 3.82.

3.47 Orthogonals. For a perfect pairing on a lattice of rank n, orthogonals are saturated, $N^\perp$ has rank $n - \operatorname{rank} N$, and ${}^\perp(N^\perp) = \operatorname{sat}(N)$. *(proved here)* Proposition 3.83.

3.48 Gram determinant of a saturated sublattice. For a perfect pairing on L over $\mathcal{O}$ and a *saturated* $L' \subseteq L$ with Gram determinant $\Delta \neq 0$: $L/L'^{\perp} \simeq L'^{\vee}$, $L' \cap L'^{\perp} = 0$, and $L/(L' \oplus L'^{\perp}) \simeq \operatorname{coker}(L' \to L'^{\vee})$ has length $v(\Delta)$ (order $\#\mathcal{O}/\Delta$ for finite k); $L'^{\perp}$ has the same Gram valuation; saturation is necessary. *(proved here)* Theorem 3.84.

3.49 Alternating pairings. Alternating implies antisymmetric (and conversely if 2 is a nonzerodivisor); odd-rank alternating Gram determinants vanish; in rank two $\Delta = a^2$ with $a\mathcal{O}$ the ideal of values; $\det = \mathrm{Pf}^2$ (stated, checked in rank 4); symplectic normal form. *(proved here, except the Pfaffian identity: stated; reference; and the normal form: proof sketched here)* Proposition 3.87.

3.50 Adjoints. For a perfect pairing $A^{\dagger} = G^{-1}A^{\mathsf{T}}G$; for a commutative algebra $\mathbb{T}$ of self-adjoint operators $(\mathfrak{a}L)^{\perp} = L[\mathfrak{a}]$, idempotents of $\mathbb{T}$ (or $\mathbb{T} \otimes S$) give orthogonal decompositions on whose summands the pairing stays perfect; if $A^{\dagger} = wAw^{-1}$ on $\mathbb{T}$ then $\langle x, wy\rangle$ is perfect with $\mathbb{T}$ self-adjoint, and alternating if $\langle\ ,\ \rangle$ is antisymmetric and $w^{\dagger} = w$. *(proved here)* Proposition 3.89.

3.51 An algebra paired with a module. If $S \times \mathbb{T} \to R$ is perfect with $\langle ts, u\rangle = \langle s, tu\rangle$, then $S \simeq \mathbb{T}^{\vee}$ as $\mathbb{T}$-modules, $S[\mathfrak{a}] \simeq \operatorname{Hom}(\mathbb{T}/\mathfrak{a}, R)$ is saturated, $\mathbb{T}$ acts faithfully, and for $\mathfrak{a} \cap \mathfrak{b} = 0$ with $\mathbb{T}/\mathfrak{a}$, $\mathbb{T}/\mathfrak{b}$ torsion-free and complementary ranks, $S/(S[\mathfrak{a}] \oplus S[\mathfrak{b}]) \simeq (\mathbb{T}/(\mathfrak{a}+\mathfrak{b}))^*$ over $\mathbb{Z}$ or $\mathbb{Z}_{\ell}$. *(proved here)* Proposition 3.91.

3.52 Finite-dimensional commutative algebras. Finitely many maximal ideals, all primes maximal, nilpotent Jacobson radical; $A \simeq \prod A_{\mathfrak{m}_i}$ via idempotents; reduced iff a product of fields; $V = \bigoplus e_i V$ with $e_i V = V_{\mathfrak{m}_i}$. *(proved here)* Theorem 3.93.

3.53 Finite free algebras over $\mathcal{O}$. Noetherian; maximal ideals contain ϖ and correspond to those of $\mathbb{T}/\varpi\mathbb{T}$; $\mathbb{T} \subseteq \mathbb{T}_K$; $\mathbb{T}$ reduced iff $\mathbb{T}_K$ is; for $\pi\colon \mathbb{T} \twoheadrightarrow \mathcal{O}$, $\mathbb{T} = \mathcal{O} \oplus \wp$, $\mathfrak{m}_{\pi} = \wp + \varpi\mathbb{T}$, and π_K factors through exactly one local factor of $\mathbb{T}_K$. *(proved here)* Theorem 3.94.

3.54 Idempotent lifting. Over a complete $\mathcal{O}$, idempotents of $\mathbb{T}/\varpi\mathbb{T}$ lift uniquely (Newton iteration $e \mapsto 3e^2 - 2e^3$); $\mathbb{T} = \prod_{\mathfrak{m}} \mathbb{T}_{\mathfrak{m}}$ with $\mathbb{T}_{\mathfrak{m}} = e_{\mathfrak{m}}\mathbb{T}$ local and finite free; $L = \bigoplus e_{\mathfrak{m}}L$; a map to a local ring factors through one $\mathbb{T}_{\mathfrak{m}}$; completeness is necessary ($\mathbb{Z}_{(11)}[x]/(x^2+x-1)$). *(proved here)* Theorem 3.95.

3.55 Hecke-type algebras. If $\mathbb{T}$ is free of finite rank over $\mathbb{Z}$, then $\mathbb{T} \otimes \mathbb{Z}_{\ell} = \prod_{\mathfrak{m} \ni \ell} \mathbb{T}_{\mathfrak{m}}$ over the maximal ideals of $\mathbb{T}$ containing ℓ. Example: the level-23 algebra $\mathbb{Z}[x]/(x^2+x-1)$ splits over $\mathbb{Z}_{11}$, and is local over $\mathbb{Z}_2$, $\mathbb{Z}_3$, $\mathbb{Z}_5$. *(proved here)* Corollary 3.96, Example 3.98.

3.56 Generalised eigenspaces. For a commutative $\mathbb{T} \subseteq \mathrm{End}_F(V)$ with split characteristic polynomials, $V = \bigoplus_{\phi} V(\phi)$ over the systems of eigenvalues, with projections the idempotents of $\mathbb{T}$, a common eigenvector in each $V(\phi)$, and $W = \bigoplus(W \cap V(\phi))$ for stable W; integrally, over a complete $\mathcal{O}$, systems of eigenvalues are $\mathcal{O}$-valued, $\mathfrak{m}_{\phi} = \mathfrak{m}_{\psi}$ iff $\phi \equiv \psi \bmod \varpi$, and $e_{\mathfrak{m}}L \otimes K = \bigoplus_{\mathfrak{m}_{\phi} = \mathfrak{m}} V(\phi)$. *(proved here)* Theorem 3.100.

3.57 Projecting a congruence. $e_{\mathfrak{m}}$ preserves L and $\mathbb{T}$-stable subspaces and fixes $V(\phi)$ for $\mathfrak{m}_{\phi} = \mathfrak{m}$; so $x \equiv y \pmod{\varpi^t L}$ with $x \in V(\phi)$ gives $x \equiv e_{\mathfrak{m}}y$. *(proved here)* Proposition 3.102.

3.58 Semisimple operators. A is semisimple iff μ_A is squarefree iff $F[A]$ is reduced (iff diagonalisable over $\overline{F}$ for perfect F); a cyclic vector makes μ_A the characteristic polynomial;

a commutative $\mathbb{T}$ is reduced iff all its elements are semisimple; Jordan-Chevalley (stated). The shift operator (U_p on oldforms) has characteristic polynomial $X^{e-1}(X^2 - aX + p)$, is not semisimple for $e \geq 3$, yet every eigenvalue has an eigenvector. *(proved here, except Jordan-Chevalley: stated; reference)* Proposition 3.104, Example 3.105.

3.59 Common eigenvectors. Over an algebraically closed field, a nonzero joint generalised eigenspace of commuting operators contains a common eigenvector of every commutative algebra containing them; for operators acting on the factors of a tensor product, $V(\lambda) = \bigotimes V_i(\lambda_i)$. *(proved here)* Lemma 3.107.

3.60 Congruence ideal (definition: for $\pi\colon \mathbb{T} \twoheadrightarrow \mathcal{O}$, $\wp = \ker \pi$, $I = \mathrm{Ann}_{\mathbb{T}}(\wp)$, $\eta = \pi(I)$; congruence module $\mathbb{T}/(\wp + I) \simeq \mathcal{O}/\eta$). Definition 3.109.

3.61 Congruence ideals. $I \neq 0$; $\eta \neq 0$ iff $\wp \cap I = 0$ iff the factor of π in $\mathbb{T}_K$ is K (proof: $\pi(t)x = tx + (\pi(t) - t)x = 0$); then $I \simeq \eta$, $\mathrm{Ann}_{\mathbb{T}}(I) = \wp$, η is the denominator of e_π; over complete $\mathcal{O}$, $\mathrm{Ann}_{\mathbb{T}}(\wp) = \mathrm{Ann}_{\mathbb{T}_\mathfrak{m}}(\wp_\mathfrak{m}) \times 0$, so η is computed in $\mathbb{T}_\mathfrak{m}$ (the other factors lie in $\wp$); η commutes with flat base change. *(proved here)* Proposition 3.110, Example 3.112.

3.62 Ingredients of Lemma lem:ddt417. For L free over $\mathcal{O}$ with a perfect pairing making $\mathbb{T}$ self-adjoint and $\eta \neq 0$: $L[\wp]$, $L[I]$ are saturated, $L[\wp] \cap L[I] = 0$, $L[\wp]^\perp = L[I]$, $Q = L/(L[\wp] \oplus L[I])$ is killed by η, and $Q \simeq (\mathcal{O}/\eta)^r$ if $L \simeq \mathbb{T}^r$. *(proved here)* Proposition 3.113, Remark 3.118.

3.63 Gorenstein algebras (definition: $\mathrm{Hom}_{\mathcal{O}}(\mathbb{T}, \mathcal{O})$ free of rank one over $\mathbb{T}$). Equivalent to a perfect pairing $\lambda(st)$; over complete $\mathcal{O}$ local by local; for local $\mathbb{T}$, iff the socle of $\mathbb{T}/\varpi\mathbb{T}$ is a line; $\mathcal{O}[x]/(f)$ and $\mathbb{T}_r$ are Gorenstein, $\mathbb{T}_3^\flat$ is not; complete intersections are Gorenstein (stated). *(proved here, except the last statement: stated; reference)* Definition 3.114, Proposition 3.115.

3.64 Mazur-style freeness. For $\mathbb{T}$ local finite free over $\mathcal{O}$ and L free over $\mathcal{O}$ with a perfect pairing making $\mathbb{T}$ self-adjoint: if $\dim L/\mathfrak{m}L = d$ and $\mathrm{rank}\, L = d\,\mathrm{rank}\,\mathbb{T}$, then $L \simeq \mathbb{T}^d$ and $\mathbb{T}$ is Gorenstein. *(proved here)* Theorem 3.116.

Where the paper uses this chapter

- **Section 1.2** (the Tamagawa factor $\mathrm{Tam}_p(M) = \mathrm{Fitt}_{\mathbb{Z}_\ell}((H^1(I_p, M)_{\mathrm{tor}})^{G_{\mathbb{Q}_p}})$): Fitting ideals and $\mathrm{Fitt} = \ell^{\mathrm{length}}$ (Definition 3.69 and Theorem 3.72).
- **Lemma lem:tamfactor** (the Tamagawa factor at a multiplicative prime): the structure $H^1(I, M) = (\mathbb{Z}_\ell/n')^2 \oplus \mathbb{Z}_\ell$ and its torsion (Theorem 3.43); the Fitting ideal of $\mathbb{Z}/\ell^v \oplus \mathbb{Z}/\ell^m$ (Theorem 3.72, Paper link 3.75).
- **Lemma lem:fpr** ($\mathrm{Fitt}_{\mathbb{Z}_\ell} H^1_f(\mathbb{Q}_p, T^D) = L_p(A_f, 1)^{-1}\,\mathrm{Tam}_p(T^D)$): Fitting ideals as lengths (Theorem 3.72); $\mathbb{Q} \cap \mathbb{Z}_\ell = \mathbb{Z}_{(\ell)}$ (Theorem 3.58(iv)).
- **Theorem thm:main, Theorem thm:dfg37, Remark rem:ns, Conjecture conj:euler** (lengths of Selmer groups and of $H^0(\mathbb{Q}, W^D)$): additivity of length (Theorem 3.65), length over $\mathbb{Z}_\ell$ (Proposition 3.66), Pontryagin duality preserves length (Theorem 3.77, Paper link 3.80).

- **Lemma lem:dfg21** (the four-term sequence with Pontryagin duals) and the paragraph after it ($H^1(\mathbb{R}, T^D)$ killed by 2): Theorems 3.76 and 3.77, Theorem 3.58(iii).
- **Lemma lem:h0** (W^D, its ℓ^k-torsion, cyclicity, Nakayama): Proposition 3.78 and Corollary 3.79, Theorem 3.35.
- **Lemma lem:crit** (congruence criterion): $\mathbb{T}/(I+J) \simeq \mathbb{Z}/\phi_f(J)$ (Theorem 3.8); $\mathbb{T} \hookrightarrow \mathbb{T}/I \times \mathbb{T}/J$ (Proposition 3.13); dualising it (Propositions 3.51 and 3.91); the congruence module of $S_2 = \mathbb{Z}f + L$ (Proposition 3.53); $\mathbb{T} \otimes \mathbb{Q} = \mathbb{Q} \times \mathbb{T}'$ and $I \cap J = 0$ (Theorem 3.93, Proposition 3.110); the passage to $\mathbb{Z}_\ell$ (Proposition 3.29). The lemma itself is proved in full in Chapter 15.
- **Lemma lem:old** (oldforms): the non-semisimple U_p and its eigenvectors (Example 3.105); common eigenforms in a tensor product (Lemma 3.107).
- **Lemma lem:IV** and Lemma lem:tamadd (T_3E free of rank one over $\mathbb{Z}_3[\zeta_3]$): Proposition 3.46(iii).
- **Section 4.1** (the pairing $\hat{\delta}_!$, perfect, alternating, with self-adjoint Hecke operators; Gram determinant $(\eta_{f,\lambda}^{\Sigma})^2$) and **Proposition prop:pullback**: Propositions 3.87 and 3.89.
- **Lemma lem:ddt417** (inequality half of DDT Lemma 4.17): every ingredient, Propositions 3.110 and 3.113 and Theorem 3.84, Proposition 3.49, summarised in Remark 3.118; the lemma itself is proved in Chapter 20.
- **Lemma lem:hecke** and the paragraph after it ($\mathbb{T}_\mathfrak{m}$, the congruence ideal computed in $\mathbb{T}_\mathfrak{m}$, $e_\mathfrak{m}$ self-adjoint): Convention 3.2, Theorem 3.95 and Corollary 3.96, Proposition 3.110(v), Proposition 3.89(iii).
- **Remark rem:free** (Gorenstein, freeness): Proposition 3.115 and Theorem 3.116, Theorem 3.35.
- **Theorem thm:twist** ($g^\perp$ as a sum of generalised eigenspaces) and **Lemma lem:step1** and **Theorem thm:quant**, Steps 1 and 2 (idempotents of $\mathbb{T}_\ell$, generalised eigenspaces, projecting a congruence, the $\mathbb{Z}_\ell$-version of Lemma lem:crit, Lemma lem:ddt417 without freeness): Theorem 3.100, Proposition 3.102, Theorem 3.95, Proposition 3.29.

3.1 Modules, submodules, quotients and homomorphisms

This section fixes the language. Every object of the paper's commutative algebra is a module over a commutative ring: the space $S_2(\Gamma_0(N);\mathbb{Z})$ of integral cusp forms and the cohomology $H^1(X_0(N),\mathbb{Z}_\ell)$ are modules over the Hecke algebra $\mathbb{T}$; the Tate module $T = T_\ell E$ is a module over $\mathbb{Z}_\ell$, and in Lemma lem:IV over $\mathbb{Z}_3[\zeta_3]$; the lattice L of Lemma lem:ddt417 is a module over an $\mathcal{O}$-algebra $\mathbb{T}$. We first record the conventions of the chapter.

Convention 3.1 (notation of the chapter)**.** The book-wide conventions of Appendix B apply, in particular B-C4 (one symbol for each dual: the linear dual $M^\vee = \mathrm{Hom}_R(M,R)$, the Pontryagin dual M^*, the Kummer dual T^D, which is not used here, and the adjoint $A^\dagger$ of an operator, never A^*; a star after the name of a map is a pullback), B-C10 ("length" without subscript is $\mathrm{length}_{\mathbb{Z}_\ell}$, and $\#X = \ell^{\mathrm{length}\,X}$ for finite $\mathbb{Z}_\ell$-modules), B-C13(a), (c) (the paper's $\mathbb{T}_\mathfrak{m}$ and its two uses of the

letter I) and B-C15(a), (h) (uniformisers are ϖ; the paper's $\pi\colon \mathbb{T} \to \mathcal{O}$ and Gram determinant Δ keep their names). In addition:

(a) Rings are commutative with 1, ring homomorphisms preserve 1 and modules are unital, as in Chapter 2, except in the Jordan-Holder theorem (Theorem 3.65). An R-algebra is a ring A with a ring homomorphism $R \to A$. The algebras $\mathbb{T}$ acting on modules, like the Hecke algebra, are commutative subrings of the (noncommutative) ring $\mathrm{End}_R(M)$.

(b) $\mathcal{O}$ is a discrete valuation ring (Theorem 3.55) with uniformiser ϖ, residue field $k = \mathcal{O}/\varpi\mathcal{O}$, fraction field K and valuation $v\colon K \to \mathbb{Z} \cup \{+\infty\}$, $v(\varpi) = 1$; $v(a\mathcal{O}) = v(a)$ for a nonzero ideal. For $\mathcal{O} = \mathbb{Z}_\ell$: $\varpi = \ell$, $k = \mathbb{F}_\ell$, $v = v_\ell$. The paper writes λ and v_λ.

(c) $M[\mathfrak{a}] = \{m \in M : am = 0 \text{ for all } a \in \mathfrak{a}\}$, $M[x] = M[xR]$ and $M[\ell^\infty] = \bigcup_k M[\ell^k]$; these are the paper's $L[\wp]$ and $L[I]$. The Pontryagin dual is $M^* = \mathrm{Hom}(M, \mathbb{Q}/\mathbb{Z})$ for a finite abelian group and $M^* = \mathrm{Hom}_{\mathbb{Z}_\ell}(M, \mathbb{Q}_\ell/\mathbb{Z}_\ell)$ for a $\mathbb{Z}_\ell$-module that is finitely generated or ℓ-primary torsion (the paper's * in Lemma lem:dfg21).

(d) Over a principal ideal domain R with fraction field K, a *lattice* is a finitely generated free R-module, and a lattice in a finite-dimensional K-vector space V is a finitely generated R-submodule spanning V (free of rank $\dim V$ by Theorem 3.40).

(e) A *pairing* is an R-bilinear map $\langle\ ,\ \rangle\colon L \times M \to R$; its Gram matrix in bases (e_i), (f_j) is $G = (\langle e_i, f_j\rangle)_{i,j}$. For $S' \subseteq L$ and $S \subseteq M$, $S'^{\perp} = \{y \in M : \langle S', y\rangle = 0\}$ is the *right* and ${}^{\perp}S = \{x \in L : \langle x, S\rangle = 0\}$ the *left* orthogonal; for a symmetric or antisymmetric pairing on $L = M$ they agree and we write $S^{\perp}$. An endomorphism t of L is *self-adjoint* if $\langle tx, y\rangle = \langle x, ty\rangle$ for all x, y.

(f) The paper's order $\#\mathcal{O}/\Delta$ is $(\#k)^{v(\Delta)}$ and makes sense only for finite k; the book writes the length $\mathrm{length}_{\mathcal{O}}(\mathcal{O}/\Delta\mathcal{O}) = v(\Delta)$.

(g) Relations are rows: a presentation $R^m \xrightarrow{A} R^n \to M \to 0$ means $M = R^n/(\text{row space of } A)$. The letter ε is not used (dual numbers are $k[x]/(x^2)$), and no Frobenius element occurs.

(h) Where the text quotes Lemma lem:crit (in the list above and in paperlinks), $I = \ker \phi_f$ and $J = \mathrm{Ann}_{\mathbb{T}}(f^{\perp})$ are that lemma's letters (J equals $\mathrm{Ann}_{\mathbb{T}}(I)$, Proposition 3.91 and its paperlink); everywhere else $I = \mathrm{Ann}_{\mathbb{T}}(\wp)$, as in Lemma lem:ddt417.

Convention 3.2 (the paper's $\mathbb{T}_{\mathfrak{m}}$)**.** Let $\mathbb{T}$ be a commutative ring that is free of finite rank as a $\mathbb{Z}$-module, and $\mathfrak{m}$ a maximal ideal of $\mathbb{T}_\ell = \mathbb{T} \otimes \mathbb{Z}_\ell$ (equivalently, by Corollary 3.96, a maximal ideal of $\mathbb{T}$ containing ℓ). Then $\mathbb{T}_{\mathfrak{m}}$ *always* means $(\mathbb{T} \otimes \mathbb{Z}_\ell)_{\mathfrak{m}}$, the direct factor $e_{\mathfrak{m}}\mathbb{T}_\ell$ of $\mathbb{T}_\ell$ cut out by an idempotent $e_{\mathfrak{m}}$ (Theorem 3.95); likewise $L_{\mathfrak{m}} = e_{\mathfrak{m}}(L \otimes \mathbb{Z}_\ell)$ for a $\mathbb{T}$-module L. The algebraic localisation of $\mathbb{T}$ itself at a maximal ideal is written $\mathbb{T}_{(\mathfrak{m})}$; it is not complete and is not a direct factor of anything. This is the paper's usage in Lemma lem:hecke, Remark rem:free and Theorem thm:quant.

Definition 3.3 (modules)**.** An *R-module* is an abelian group M with a map $R \times M \to M$, $(r, m) \mapsto rm$, such that $r(m + m') = rm + rm'$, $(r + r')m = rm + r'm$, $(rr')m = r(r'm)$ and $1m = m$. A *submodule* is a subgroup $N \subseteq M$ with $RN \subseteq N$, and the *quotient* M/N is the module of cosets with $r(m + N) = rm + N$. The submodule generated by a family (m_i) is $\sum_i Rm_i$, the set of finite sums $\sum r_i m_i$; M is *finitely generated* (f.g.) if $M = \sum_{i=1}^n Rm_i$ for some $m_1, \ldots, m_n$,

and *cyclic* if $M = Rm$. A *homomorphism* (R-linear map) $f\colon M \to N$ is a group homomorphism with $f(rm) = rf(m)$; its kernel $\ker f$, image $f(M) = \operatorname{im} f$ and cokernel $\operatorname{coker} f = N/f(M)$ are modules. $\operatorname{Hom}_R(M,N)$ is the set of homomorphisms and $\operatorname{End}_R(M) = \operatorname{Hom}_R(M,M)$.

Proposition 3.4. *(i)* $\operatorname{Hom}_R(M,N)$ *is an* R*-module under* $(f+g)(m) = f(m)+g(m)$ *and* $(rf)(m) = rf(m)$*, and* $\operatorname{End}_R(M)$ *is a ring under composition, with an* R*-algebra structure* $R \to \operatorname{End}_R(M)$*,* $r \mapsto (m \mapsto rm)$*.*

(ii) For $m \in M$ *let* $\operatorname{Ann}_R(m) = \{r \in R : rm = 0\}$*. Then* $\operatorname{Ann}_R(m)$ *is an ideal and* $R/\operatorname{Ann}_R(m) \simeq Rm$*,* $r \mapsto rm$*.*

Proof. (i) rf is R-linear because R is commutative: $(rf)(sm) = rsf(m) = s(rf)(m)$. This is the only place where commutativity matters; over a noncommutative ring rf would in general not be linear. The module axioms for $\operatorname{Hom}_R(M,N)$ are inherited pointwise from those of N: for instance $((r+r')f)(m) = (r+r')f(m) = rf(m)+r'f(m) = (rf+r'f)(m)$. Composition of linear maps is linear and distributes over the sum, so $\operatorname{End}_R(M)$ is a ring with unit id_M. The map $r \mapsto (m \mapsto rm)$ preserves sums and products by the module axioms ($(rr')m = r(r'm)$), sends 1 to id_M, and its image is central: for $g \in \operatorname{End}_R(M)$, $g(rm) = rg(m)$ is exactly the statement that g commutes with multiplication by r. (ii) The map $R \to Rm$, $r \mapsto rm$, is R-linear and surjective with kernel $\operatorname{Ann}_R(m)$; apply Theorem 3.8(i) below (whose proof does not use this proposition). □

Example 3.5. A $\mathbb{Z}$-module is an abelian group, with $nm = m + \cdots + m$; a module over a field K is a K-vector space. A module over the polynomial ring $K[x]$ is a K-vector space V together with one endomorphism (the action of x); submodules are the subspaces stable under it. This dictionary underlies Section 3.10. A module over $R/\mathfrak{a}$ is the same as an R-module killed by $\mathfrak{a}$. The submodules of R are its ideals.

Definition 3.6 (algebras acting on modules)**.** Let $\phi\colon R \to S$ be a ring homomorphism. Every S-module M is an R-module by $rm = \phi(r)m$ (*restriction of scalars*). If A is an R-algebra and M an R-module, an *action* of A on M is a homomorphism of R-algebras $A \to \operatorname{End}_R(M)$; equivalently, an A-module structure on M whose restriction to R is the given one. The action is *faithful* if $A \to \operatorname{End}_R(M)$ is injective.

Example 3.7 (running examples)**.** (a) A module over $R_1 \times R_2$ is the same as a pair of modules: with the idempotents $e_1 = (1,0)$ and $e_2 = (0,1)$ (Chapter 2), $M = e_1M \oplus e_2M$, where e_iM is an R_i-module, and every pair (M_1, M_2) arises from $M_1 \times M_2$. This is how a module over $\mathbb{T} \otimes \mathbb{Z}_\ell = \prod_{\mathfrak{m}} \mathbb{T}_{\mathfrak{m}}$ splits (Theorem 3.95).

(b) The Hecke algebra $\mathbb{T} \subset \operatorname{End}_{\mathbb{Z}} S_2(\Gamma_0(N);\mathbb{Z})$ acts faithfully on the integral cusp forms, by definition (Chapters 12 and 13); it also acts on $H^1(X_0(N),\mathbb{Z}_\ell)$ (Chapter 14).

(c) Let T be a free $\mathbb{Z}_3$-module of rank 2 and $\sigma \in \operatorname{Aut}(T)$ with $\sigma^2 + \sigma + 1 = 0$ (the generator of the image of inertia in Lemma lem:IV). Then T is a module over $\mathbb{Z}_3[X]/(X^2+X+1)$, with X acting as σ; this ring is $\mathbb{Z}_3[\zeta_3]$, a discrete valuation ring (Chapter 6). Proposition 3.46(iii) shows that T is free of rank one over it.

(d) The toy Hecke algebras of Example 3.112, which are the smallest algebras exhibiting a congruence.

Theorem 3.8 (isomorphism theorems). *(i) For $f\colon M\to N$, $m+\ker f\mapsto f(m)$ is an isomorphism $M/\ker f\simeq f(M)$.*

(ii) For submodules $A,B\subseteq M$, $(A+B)/B\simeq A/(A\cap B)$.

(iii) For submodules $B\subseteq A\subseteq M$, $(M/B)/(A/B)\simeq M/A$, and $A\mapsto A/B$ is an inclusion-preserving bijection between submodules of M containing B and submodules of M/B.

(iv) If $f\colon M\to N$ is surjective with kernel K_0 and $A\subseteq M$ is a submodule, then f induces an isomorphism $M/(K_0+A)\simeq N/f(A)$.

Proof. (i) The map is well defined and injective because $f(m)=f(m')$ iff $m-m'\in\ker f$; it is R-linear and onto $f(M)$. (ii) Apply (i) to $A\to(A+B)/B$, $a\mapsto a+B$, which is surjective (every $a+b+B$ equals $a+B$) with kernel $A\cap B$. (iii) Apply (i) to $M/B\to M/A$, $m+B\mapsto m+A$, surjective with kernel A/B. A submodule $X\subseteq M/B$ is the image of its preimage, which contains B, and $A=\{m : m+B\in A/B\}$ for $A\supseteq B$. (iv) The composite $M\to N\to N/f(A)$ is surjective; its kernel is $f^{-1}(f(A))$. This equals $A+K_0$: if $f(m)=f(a)$ with $a\in A$, then $m-a\in K_0$, so $m\in A+K_0$; conversely $f(a+k)=f(a)$ for $k\in K_0$. Apply (i). □

Part (iii) is used constantly in the form "a submodule of a quotient is the image of a submodule containing what was divided out"; for instance the subgroups of $\mathbb{Z}/n$ are the $d\mathbb{Z}/n\mathbb{Z}$ for $d\mid n$, the images of the subgroups $d\mathbb{Z}\supseteq n\mathbb{Z}$. Part (iv) says that dividing first by the kernel of f and then by $f(A)$ is the same as dividing by K_0+A at once.

In the paper 3.9. Lemma lem:crit writes "$\mathbb{T}/(I+J)\simeq\mathbb{Z}/\phi_f(J)$". This is Theorem 3.8(iv) for the surjection $\phi_f\colon\mathbb{T}\to\mathbb{Z}$ with kernel I and the submodule $A=J$. In the same way the congruence module of Definition 3.109 is $\mathbb{T}/(\wp+I)\simeq\mathcal{O}/\pi(I)$ for $\pi\colon\mathbb{T}\twoheadrightarrow\mathcal{O}$ with kernel $\wp$. A toy case: for $\mathbb{T}=\mathbb{Z}[x]/(x^2-4)$, $\phi(x)=2$, the kernel is $I=(x-2)$; take $J=(x+2)$. In $\mathbb{T}/(I+J)$ one has $x\equiv 2$ and $x\equiv -2$, hence $4\equiv 0$, and $\mathbb{T}/(I+J)\simeq\mathbb{Z}/4$; on the other side $\phi(J)=\phi(x+2)\phi(\mathbb{T})=4\mathbb{Z}$, so $\mathbb{Z}/\phi(J)=\mathbb{Z}/4$ as (iv) predicts. This algebra returns in Example 3.112(b) as the smallest example of a congruence modulo 4.

3.2 Exact sequences, the snake lemma, sums, free and projective modules

Exact sequences are the bookkeeping device of the whole book. The paper's identity (eq:identity) is obtained by adding lengths along the four-term exact sequence of Lemma lem:dfg21, and every connecting map of Chapter 16 is built from the snake lemma proved here. The sequence of two submodules (Proposition 3.13) is the exact form of two sentences of the paper: "the inclusion $\mathbb{T}\subset\mathbb{T}/I\times\mathbb{T}/J$, whose cokernel is $\mathbb{T}/(I+J)$" in Lemma lem:crit, and the directness of the sum $L[\wp]+L[I]$ in Lemma lem:ddt417. Projective modules enter because the local factors $e\mathbb{T}$ of a finite free $\mathbb{Z}_\ell$-algebra are again free over $\mathbb{Z}_\ell$.

Definition 3.10 (exact sequences). A sequence of homomorphisms $\cdots\to M_{i-1}\xrightarrow{f_{i-1}}M_i\xrightarrow{f_i}M_{i+1}\to\cdots$ is *exact at M_i* if $\ker f_i=\operatorname{im} f_{i-1}$, and *exact* if it is exact at every interior term. A *short exact sequence* is an exact sequence $0\to M'\xrightarrow{i}M\xrightarrow{p}M''\to 0$: i is injective, p is surjective and $\operatorname{im} i=\ker p$, so $M''\simeq M/i(M')$. It *splits* if the equivalent conditions of Lemma 3.11 hold.

Lemma 3.11 (splitting lemma)**.** *For a short exact sequence* $0 \to M' \xrightarrow{i} M \xrightarrow{p} M'' \to 0$ *the following are equivalent: (a) there is* $s\colon M'' \to M$ *with* $ps = \mathrm{id}$*; (b) there is* $r\colon M \to M'$ *with* $ri = \mathrm{id}$*; (c) there is an isomorphism* $\theta\colon M \to M' \oplus M''$ *with* $\theta i(x) = (x, 0)$ *and* $p\theta^{-1}(x, y) = y$*.*

Proof. (a)⇒(c): for $m \in M$, $m - sp(m) \in \ker p = \operatorname{im} i$, so $m - sp(m) = i(r(m))$ for a unique $r(m) \in M'$; put $\theta(m) = (r(m), p(m))$, with inverse $(x, y) \mapsto i(x) + s(y)$. Indeed r is linear by the uniqueness of $r(m)$, and $i(r(m)) + s(p(m)) = m$ by construction; conversely, for $m = i(x) + s(y)$ one has $p(m) = ps(y) = y$ and $m - sp(m) = i(x)$, so $r(m) = x$. The two compatibilities hold: $\theta i(x) = (x, 0)$ because $pi = 0$ and $r(i(x)) = x$, and $p\theta^{-1}(x, y) = p(i(x) + s(y)) = y$. (b)⇒(c): put $\theta(m) = (r(m), p(m))$. It is injective: if $p(m) = 0$ then $m = i(x)$ and $r(m) = x$, so $r(m) = 0$ forces $m = 0$. It is surjective: given (x, y), choose m with $p(m) = y$; then $m' = m + i(x - r(m))$ has $\theta(m') = (x, y)$. (c)⇒(a),(b): take $s(y) = \theta^{-1}(0, y)$ and r the first component of θ. □

Example 3.12. The sequence $0 \to \mathbb{Z} \xrightarrow{n} \mathbb{Z} \to \mathbb{Z}/n \to 0$ does not split for $n \geq 2$, since $\mathbb{Z}$ has no element of order n. Likewise $0 \to \mathbb{Z}_\ell \xrightarrow{\ell^k} \mathbb{Z}_\ell \to \mathbb{Z}/\ell^k \to 0$ does not split for $k \geq 1$. If $T \neq 0$ is a free $\mathbb{Z}_\ell$-module of finite rank, $V = T \otimes \mathbb{Q}_\ell$ and $W = T \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$, the sequence $0 \to T \to V \to W \to 0$ (Proposition 3.78) does not split: a splitting would embed the torsion module $W \neq 0$ into V, which has no nonzero torsion.

Proposition 3.13 (two submodules)**.** *For submodules* A, B *of* M *the sequence*

$$0 \to M/(A \cap B) \xrightarrow{x \mapsto (x,x)} M/A \oplus M/B \xrightarrow{(y,z) \mapsto y - z} M/(A + B) \to 0$$

is exact. In particular, if $A \cap B = 0$ *then* $M \hookrightarrow M/A \oplus M/B$ *with cokernel* $M/(A + B)$*. The sum* $A + B$ *is direct (that is,* $A \oplus B \to A + B$*,* $(a, b) \mapsto a + b$*, is an isomorphism) if and only if* $A \cap B = 0$*.*

Proof. The first map is well defined and injective: $(x + A, x + B) = 0$ iff $x \in A \cap B$. The second is surjective, and the composite is zero. If $y - z \in A + B$, say $y - z = a + b$, then $x = y - a = z + b$ satisfies $(x + A, x + B) = (y + A, z + B)$, which is exactness in the middle. The last statement: the kernel of $(a, b) \mapsto a + b$ is $\{(c, -c) : c \in A \cap B\}$. This is the module form of the two-ideal sequence of Chapter 2. □

In the paper 3.14. In Lemma lem:crit, $I \cap J = 0$ in $\mathbb{T}$, so Proposition 3.13 gives $\mathbb{T} \hookrightarrow \mathbb{T}/I \times \mathbb{T}/J$ with cokernel $\mathbb{T}/(I + J)$; Proposition 3.91(iii) dualises this inclusion. In Lemma lem:ddt417 the directness of $L[\wp] + L[I]$ is the statement $L[\wp] \cap L[I] = 0$, proved in Proposition 3.113(ii).

Lemma 3.15 (the snake lemma)**.** *Consider a commutative diagram with exact rows*

$$\begin{array}{cccccccc} & M' & \xrightarrow{i} & M & \xrightarrow{p} & M'' & \to 0 \\ & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f''} & \\ 0 \to & N' & \xrightarrow{j} & N & \xrightarrow{q} & N'' & \end{array}$$

(so $fi = jf'$ *and* $f''p = qf$*). There is an* R*-linear map* $\delta\colon \ker f'' \to \operatorname{coker} f'$ *defined as follows: for* $x'' \in \ker f''$ *choose* $x \in M$ *with* $p(x) = x''$*; then* $q(f(x)) = f''(x'') = 0$*, so* $f(x) = j(y')$ *for a unique* $y' \in N'$*; put* $\delta(x'') = y' + f'(M')$*. It is well defined, and the sequence*

$$\ker f' \xrightarrow{i} \ker f \xrightarrow{p} \ker f'' \xrightarrow{\delta} \operatorname{coker} f' \xrightarrow{\bar{j}} \operatorname{coker} f \xrightarrow{\bar{q}} \operatorname{coker} f''$$

is exact. If i *is injective, so is* $\ker f' \to \ker f$*; if* q *is surjective, so is* $\operatorname{coker} f \to \operatorname{coker} f''$*.*

Proof. The restrictions of i, p map kernels to kernels, and j, q induce maps of cokernels, by commutativity. *δ is well defined.* The element y' is unique because j is injective. If x_1 is another lift of x'', then $x_1 - x = i(m')$ with $m' \in M'$, and $f(x_1) - f(x) = fi(m') = j(f'(m'))$, so y' changes by $f'(m')$, which does not change its class. Linearity follows from the same uniqueness: if x lifts x'' and $\tilde{x}$ lifts $\tilde{x}''$, with $f(x) = j(y')$ and $f(\tilde{x}) = j(\tilde{y}')$, then $x + r\tilde{x}$ lifts $x'' + r\tilde{x}''$ and $f(x + r\tilde{x}) = j(y' + r\tilde{y}')$, so $\delta(x'' + r\tilde{x}'') = \delta(x'') + r\delta(\tilde{x}'')$. *Exactness at* $\ker f$. $pi = 0$. If $x \in \ker f$ and $p(x) = 0$, then $x = i(m')$ and $jf'(m') = f(x) = 0$, so $f'(m') = 0$ as j is injective: $m' \in \ker f'$. *Exactness at* $\ker f''$. If $x'' = p(x)$ with $x \in \ker f$, take this x as the lift: $f(x) = 0$, so $\delta(x'') = 0$. Conversely, if $\delta(x'') = 0$ then $f(x) = j(f'(m')) = f(i(m'))$ for some m', so $x - i(m') \in \ker f$ maps to x''. *Exactness at* $\operatorname{coker} f'$. $\bar{j}\delta(x'')$ is the class of $j(y') = f(x)$, which is 0 in $\operatorname{coker} f$. Conversely, if $j(y') = f(x)$ for some $x \in M$, then $x'' = p(x)$ satisfies $f''(x'') = qf(x) = qj(y') = 0$, and $\delta(x'') = [y']$ by construction. *Exactness at* $\operatorname{coker} f$. $qj = 0$. If $q(y) = f''(x'')$, write $x'' = p(x)$; then $q(y - f(x)) = 0$, so $y - f(x) = j(y')$ and $[y] = \bar{j}[y']$. The last two assertions: $\ker f' \to \ker f$ is a restriction of i, so it is injective when i is; and if q is surjective, every class $[z] \in \operatorname{coker} f''$ is $[q(y)] = \bar{q}[y]$. □

The way to remember δ is the path it follows through the diagram: up from $\ker f''$ to M'', back along p to M, down by f to N, and back along j to N'. Each backward step is possible only up to an ambiguity (the choice of a lift along p) or only because of an exactness property ($f(x)$ lands in $\ker q = \operatorname{im} j$), and the proof checks that the ambiguity dies in $\operatorname{coker} f'$. Every connecting homomorphism of group cohomology in Chapter 16 is built this way.

Corollary 3.16. *(a) For a short exact sequence $0 \to A \to B \to C \to 0$ and $n \in R$ there is an exact sequence*

$$0 \to A[n] \to B[n] \to C[n] \to A/nA \to B/nB \to C/nC \to 0.$$

(b) If ϕ is an endomorphism of a finite abelian group A, then $\#\ker\phi = \#\operatorname{coker}\phi$.

Proof. (a) Apply Lemma 3.15 to the diagram whose two rows are the given sequence and whose vertical maps are multiplication by n. The squares commute because the maps of the sequence are R-linear. The kernel of multiplication by n on A is $A[n]$ and its cokernel is A/nA, and likewise for B and C; both end maps behave as stated because $A \to B$ is injective and $B \to C$ surjective. (b) By Theorem 3.8(i), $A/\ker\phi \simeq \operatorname{im}\phi$, so $\#A = \#\ker\phi \cdot \#\operatorname{im}\phi$; and $\operatorname{coker}\phi = A/\operatorname{im}\phi$, so $\#A = \#\operatorname{im}\phi \cdot \#\operatorname{coker}\phi$. Compare the two. □

For example, multiplication by 2 on $\mathbb{Z}/4$ has kernel $\{0, 2\}$ and cokernel $(\mathbb{Z}/4)/(2\mathbb{Z}/4) \simeq \mathbb{Z}/2$, both of order 2. Part (b) fails for infinite groups: multiplication by 2 on $\mathbb{Z}$ has kernel 0 and cokernel $\mathbb{Z}/2$. Part (a) with $n = \ell^k$ is how the ℓ^k-torsion of the coefficient module W is related to $T/\ell^k T$ in Proposition 3.78(ii).

Lemma 3.17 (the five lemma)**.** *Consider a commutative diagram with exact rows $M_1 \to M_2 \to M_3 \to M_4 \to M_5$ and $N_1 \to N_2 \to N_3 \to N_4 \to N_5$ and vertical maps $f_i\colon M_i \to N_i$. If f_2, f_4 are injective and f_1 is surjective, then f_3 is injective; if f_2, f_4 are surjective and f_5 is injective, then f_3 is surjective. In particular, if f_1, f_2, f_4, f_5 are isomorphisms, so is f_3.*

Proof. Write $a_i\colon M_i \to M_{i+1}$ and $b_i\colon N_i \to N_{i+1}$. *Injectivity.* Let $f_3(x) = 0$. Then $f_4a_3(x) = b_3f_3(x) = 0$, so $a_3(x) = 0$ and $x = a_2(y)$. Now $b_2f_2(y) = f_3(x) = 0$, so $f_2(y) = b_1(z)$, and $z = f_1(w)$. Then $f_2(y - a_1(w)) = b_1(z) - b_1f_1(w) = 0$, so $y = a_1(w)$ and $x = a_2a_1(w) = 0$. *Surjectivity.* Let $u \in N_3$. Write $b_3(u) = f_4(x)$. Then $f_5a_4(x) = b_4b_3(u) = 0$, so $a_4(x) = 0$ and $x = a_3(y)$. Now $b_3(u - f_3(y)) = 0$, so $u - f_3(y) = b_2(v)$ with $v = f_2(w)$, and $u = f_3(y + a_2(w))$. □

Definition 3.18 (direct sums and products)**.** For a family $(M_i)_{i\in I}$ the *direct product* $\prod_i M_i$ is the set of all families (m_i) with componentwise operations, and the *direct sum* $\bigoplus_i M_i$ is the submodule of families with finitely many nonzero terms. If the M_i are submodules of M, the sum $\sum M_i$ is *direct*, written $\bigoplus M_i$ (internal direct sum), if the map $\bigoplus_i M_i \to M$ is injective.

Proposition 3.19. *(i) By restriction to the summands and composition with the projections,*

$$\operatorname{Hom}_R\Big(\bigoplus_i M_i, N\Big) = \prod_i \operatorname{Hom}_R(M_i, N), \qquad \operatorname{Hom}_R\Big(N, \prod_i M_i\Big) = \prod_i \operatorname{Hom}_R(N, M_i).$$

For finite I, $\bigoplus_i M_i = \prod_i M_i$.

(ii) For submodules $A, B \subseteq M$ the following are equivalent: $M = A \oplus B$ internally; $A + B = M$ and $A \cap B = 0$; there is an idempotent $e \in \operatorname{End}_R(M)$ with $eM = A$ and $(1-e)M = B$.

Proof. (i) A map out of $\bigoplus M_i$ is determined by its restrictions, which may be arbitrary because each element is a finite sum; a map into $\prod M_i$ is the family of its components. (ii) The first two conditions agree by Proposition 3.13. If $M = A \oplus B$, every m is uniquely $a + b$, so $e(a + b) = a$ is well defined, and it is linear because the decomposition of $rm + m'$ is the corresponding combination of decompositions; then $e^2 = e$, $eM = A$, and $(1 - e)(a + b) = b$ gives $(1 - e)M = B$. Conversely, given e, every $m = em + (1 - e)m$, and $x \in A \cap B$ gives $x = ex'$, $x = (1 - e)x''$, so $x = ex = e(1 - e)x'' = 0$. □

Definition 3.20 (free modules)**.** A family $(e_i)_{i\in I}$ in M is a *basis* if every $m \in M$ is uniquely a finite sum $\sum r_i e_i$. A module with a basis is *free*; $R^{(I)} = \bigoplus_{i\in I} R$ is free with the standard basis, and $R^n = R^{(\{1,\dots,n\})}$. A *presentation* of M is an exact sequence $F_1 \to F_0 \to M \to 0$ with F_0, F_1 free; M is *finitely presented* if F_0 and F_1 can be taken of finite rank.

Proposition 3.21. *(i) (Universal property.) For any family $(m_i)_{i\in I}$ in N there is a unique homomorphism $R^{(I)} \to N$ with $e_i \mapsto m_i$. Hence every module is a quotient of a free module and has a presentation.*

(ii) (Rank.) If $R \neq 0$ and $R^m \simeq R^n$, then $m = n$.

(iii) A matrix $A \in \mathrm{M}_n(R)$ is invertible if and only if $\det A \in R^\times$; an endomorphism of R^n is an automorphism if and only if the determinant of its matrix is a unit.

Proof. (i) Send $\sum r_i e_i$ to $\sum r_i m_i$. Taking all elements of M as the family gives $R^{(M)} \twoheadrightarrow M$; its kernel is again a quotient of a free module, which gives F_1. (ii) Let $\mathfrak{m}$ be a maximal ideal of R; it exists by Zorn's lemma (Chapter 2), or by Proposition 3.31(iii) when R is Noetherian. By Theorem 3.26(ii), $R^m \simeq R^n$ gives $(R/\mathfrak{m})^m \simeq (R/\mathfrak{m})^n$ as vector spaces over the field $R/\mathfrak{m}$, so $m = n$ by linear algebra. (We use the tensor product before proving its properties only to keep the statement here; the proof of Theorem 3.26 does not use (ii).) (iii) If $AB = 1$ then $\det A \det B = 1$. Conversely, the adjugate satisfies $A \operatorname{adj}(A) = \operatorname{adj}(A) A = \det(A) \cdot 1$ over any commutative ring (the identity is a polynomial identity in the entries, true over $\mathbb{Z}[x_{ij}]$), so $A^{-1} = \det(A)^{-1} \operatorname{adj}(A)$. □

Definition 3.22 (projective modules)**.** A module P is *projective* if the equivalent conditions of Proposition 3.23 hold.

Proposition 3.23. *For an R-module P the following are equivalent: (a) every surjection $M \twoheadrightarrow P$ splits; (b) P is a direct summand of a free module; (c) $\mathrm{Hom}_R(P,-)$ is exact, that is, carries short exact sequences to short exact sequences; (d) for every surjection $g\colon M \twoheadrightarrow N$ and every $h\colon P \to N$ there is $\tilde h\colon P \to M$ with $g\tilde h = h$. Free modules are projective, and so is eR for every idempotent $e \in R$; so each factor R_i of $R = \prod R_i$ is a projective R-module. The $\mathbb{Z}/6$-module $\mathbb{Z}/2 \simeq 3\mathbb{Z}/6$ is projective and not free.*

Proof. (a)⇒(b): split a surjection $R^{(P)} \twoheadrightarrow P$ and use Lemma 3.11. (b)⇒(d): let $F = P \oplus Q$ be free with basis (e_i); extend h by 0 on Q, lift each image $h(e_i)$ to M and use the universal property of F; restrict the lift to P. (d)⇒(a): lift id_P along $M \twoheadrightarrow P$. (c)⇔(d): $\mathrm{Hom}(P,-)$ is always left exact (Proposition 3.25(ii)), and (d) is exactly surjectivity of $\mathrm{Hom}(P,M) \to \mathrm{Hom}(P,N)$. For an idempotent e, $R = eR \oplus (1-e)R$. Under $\mathbb{Z}/6 \simeq \mathbb{Z}/2 \times \mathbb{Z}/3$ the module $\mathbb{Z}/2$ is the first factor, so it is projective; it is not free because a nonzero free $\mathbb{Z}/6$-module has at least 6 elements. □

Remark 3.24. Over a local ring every finitely generated projective module is free (Theorem 3.35(v)), and over a principal ideal domain every submodule of a free module is free (Theorem 3.40). Consequently, if $\mathbb{T}$ is a commutative $\mathbb{Z}_\ell$-algebra that is finite and free as a $\mathbb{Z}_\ell$-module and $e \in \mathbb{T}$ is an idempotent, then $e\mathbb{T}$ is a direct summand of $\mathbb{T}$, hence a finitely generated free $\mathbb{Z}_\ell$-module. This is why the local factors $\mathbb{T}_{\mathfrak{m}}$ in Lemma lem:hecke and Theorem thm:quant are again finite free $\mathbb{Z}_\ell$-algebras, to which Lemma lem:ddt417 applies.

3.3 Hom and tensor product; flatness

The paper changes coefficients constantly: $\mathbb{T} \otimes \mathbb{Z}_\ell$ and $\mathbb{T} \otimes \mathbb{Q}$ in Lemmas lem:crit and lem:hecke and in Theorem thm:quant, $W = \mathrm{ad}^0 T \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$ in Theorem thm:main and Lemma lem:h0, and the sentence "The same statements hold with $\mathbb{Z}$ replaced by $\mathbb{Z}_\ell$ and r by its ℓ-part" at the end of Lemma lem:crit. This section proves what makes such changes harmless: Hom is left exact, the tensor product is right exact, and tensoring with a flat module such as $\mathbb{Z}_\ell$ or $\mathbb{Q}$ (over $\mathbb{Z}$) commutes with kernels, annihilators and saturation.

Proposition 3.25 (Hom)**.** *(i)* $\mathrm{Hom}_R(R,M) \simeq M$ *by* $f \mapsto f(1)$*;* $\mathrm{Hom}_R(R^n,M) \simeq M^n$*; and* $\mathrm{Hom}_R(R/\mathfrak{a},M) \simeq M[\mathfrak{a}]$ *by* $f \mapsto f(1)$*.*

(ii) $\mathrm{Hom}_R(N,-)$ *and* $\mathrm{Hom}_R(-,N)$ *are left exact: if* $0 \to M' \xrightarrow{i} M \xrightarrow{p} M''$ *is exact then so is* $0 \to \mathrm{Hom}(N,M') \to \mathrm{Hom}(N,M) \to \mathrm{Hom}(N,M'')$*, and if* $M' \xrightarrow{i} M \xrightarrow{p} M'' \to 0$ *is exact then so is* $0 \to \mathrm{Hom}(M'',N) \to \mathrm{Hom}(M,N) \to \mathrm{Hom}(M',N)$*.*

(iii) Neither is right exact in general: applying $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/2,-)$ *to* $0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \mathbb{Z}/2 \to 0$ *gives* $0 \to 0 \to 0 \to \mathbb{Z}/2$*, and applying* $\mathrm{Hom}_{\mathbb{Z}}(-,\mathbb{Z})$ *gives* $0 \to 0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z}$*; in both the last map is not surjective.*

(iv) For M free with basis $e_1,\dots,e_n$, $M^\vee = \mathrm{Hom}_R(M,R)$ is free with the dual basis *$e_i^\vee$, $e_i^\vee(e_j) = \delta_{ij}$, and the evaluation map $M \to M^{\vee\vee}$, $m \mapsto (\varphi \mapsto \varphi(m))$, is an isomorphism. Over a domain $M^\vee$ is torsion-free for every M.*

Proof. (i) A homomorphism out of R is determined by the image of 1, which may be arbitrary; out of $R/\mathfrak{a}$ the image of 1 must be killed by $\mathfrak{a}$, and every such element occurs. (ii) For the first sequence: if $if = 0$ then $f = 0$ since i is injective; if $pf = 0$ then $f(N) \subseteq \ker p = i(M')$ and

$f = ig$ with $g = i^{-1}f$. For the second: if $fp = 0$ then $f = 0$ as p is surjective; if $fi = 0$ then f vanishes on $\ker p$ and factors through $M/\ker p \simeq M''$. (iii) $\mathrm{Hom}(\mathbb{Z}/2, \mathbb{Z}) = 0$, and $\mathrm{Hom}(\mathbb{Z}, \mathbb{Z}) = \mathbb{Z}$ with the induced map multiplication by 2. (iv) $\varphi = \sum \varphi(e_i) e_i^\vee$, and the evaluation map sends e_i to the dual basis of $(e_i^\vee)$. Over a domain, $r\varphi = 0$ with $r \neq 0$ gives $r\varphi(m) = 0$, so $\varphi(m) = 0$ for all m. □

Theorem 3.26 (tensor product)**.** *(i) For R-modules M, N there is an R-module $M \otimes_R N$ with an R-bilinear map $M \times N \to M \otimes_R N$, $(m, n) \mapsto m \otimes n$, such that every bilinear map $b\colon M \times N \to P$ factors uniquely as $b(m, n) = \beta(m \otimes n)$ with β linear. It is unique up to unique isomorphism, and generated by the elements $m \otimes n$.*

(ii) $R \otimes M \simeq M$; $(\bigoplus_i M_i) \otimes N \simeq \bigoplus_i (M_i \otimes N)$; $R^m \otimes R^n \simeq R^{mn}$; $(R/\mathfrak{a}) \otimes M \simeq M/\mathfrak{a}M$; $M \otimes N \simeq N \otimes M$ and $(M \otimes N) \otimes P \simeq M \otimes (N \otimes P)$.

(iii) (Adjunction.) $\mathrm{Hom}_R(M \otimes N, P) \simeq \mathrm{Hom}_R(M, \mathrm{Hom}_R(N, P))$, $\beta \mapsto (m \mapsto (n \mapsto \beta(m \otimes n)))$.

(iv) (Base change.) For an R-algebra S, $S \otimes_R M$ is an S-module by $s(s' \otimes m) = ss' \otimes m$; $S \otimes_R R^n \simeq S^n$ and $S \otimes_R (R/\mathfrak{a}) \simeq S/\mathfrak{a}S$. If A, B are R-algebras, $A \otimes_R B$ is an R-algebra with $(a \otimes b)(a' \otimes b') = aa' \otimes bb'$.

Proof. (i) Let F be the free module on the set $M \times N$ and F_0 its submodule generated by the elements $(m + m', n) - (m, n) - (m', n)$, $(m, n + n') - (m, n) - (m, n')$, $(rm, n) - r(m, n)$ and $(m, rn) - r(m, n)$. Put $M \otimes N = F/F_0$ and $m \otimes n$ the class of (m, n); the map is bilinear by construction. A bilinear b defines a linear map $F \to P$ (Proposition 3.21(i)) that kills F_0 because b is bilinear, hence β; it is unique because the $m \otimes n$ generate. Uniqueness up to unique isomorphism is the usual consequence of a universal property. (ii) Each isomorphism is produced by the universal property from an evident bilinear map, with inverse written down directly: $r \otimes m \mapsto rm$ with inverse $m \mapsto 1 \otimes m$; $(m_i) \otimes n \mapsto (m_i \otimes n)$ with inverse given on each summand; $R^m \otimes R^n$ follows, with basis $e_i \otimes e_j$; for $R/\mathfrak{a}$, the bilinear map $(\bar{r}, m) \mapsto rm + \mathfrak{a}M$ gives $(R/\mathfrak{a}) \otimes M \to M/\mathfrak{a}M$, with inverse $m + \mathfrak{a}M \mapsto \bar{1} \otimes m$, well defined because $\bar{1} \otimes am = \bar{a} \otimes m = 0$ for $a \in \mathfrak{a}$. Commutativity and associativity are proved in the same way. The bilinear map $(m, n) \mapsto n \otimes m$ gives $M \otimes N \to N \otimes M$, and $(n, m) \mapsto m \otimes n$ its inverse. For associativity fix $p \in P$; then $(m, n) \mapsto m \otimes (n \otimes p)$ is bilinear, giving $\gamma_p\colon M \otimes N \to M \otimes (N \otimes P)$, and $(z, p) \mapsto \gamma_p(z)$ is bilinear on $(M \otimes N) \times P$, giving $(M \otimes N) \otimes P \to M \otimes (N \otimes P)$ with $(m \otimes n) \otimes p \mapsto m \otimes (n \otimes p)$; the inverse is built symmetrically, and the two composites are the identity on the generators, hence everywhere. (iii) Bilinear maps $M \times N \to P$ are exactly the linear maps $M \to \mathrm{Hom}(N, P)$. (iv) For fixed s, multiplication by s on S is R-linear and induces the action on $S \otimes M$; the rest follows from (ii). The product on $A \otimes B$ is induced by the R-multilinear map $(a, b, a', b') \mapsto aa' \otimes bb'$. □

Example 3.27. Over $\mathbb{Z}$ (all isomorphisms by Theorem 3.26(ii)):

tensor product	value
$\mathbb{Z}/m \otimes \mathbb{Z}/n$	$\mathbb{Z}/(m\mathbb{Z} + n\mathbb{Z}) = \mathbb{Z}/\gcd(m, n)$
$\mathbb{Q} \otimes \mathbb{Z}/n$	$\mathbb{Q}/n\mathbb{Q} = 0$
$\mathbb{Z}_\ell \otimes \mathbb{Z}/n$	$\mathbb{Z}_\ell/n\mathbb{Z}_\ell \simeq \mathbb{Z}/\ell^{v_\ell(n)}$ (Theorem 3.58(iii): $n = \ell^{v_\ell(n)}u$ with $u \in \mathbb{Z}_\ell^\times$)
$\mathbb{Q}_\ell/\mathbb{Z}_\ell \otimes A$, A torsion	0
$\mathbb{Q}_\ell/\mathbb{Z}_\ell \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$	0

The first row is $(R/\mathfrak{a}) \otimes M \simeq M/\mathfrak{a}M$ with $\mathfrak{a} = m\mathbb{Z}$ and $M = \mathbb{Z}/n$: the quotient of $\mathbb{Z}/n$ by $m(\mathbb{Z}/n) = (m\mathbb{Z} + n\mathbb{Z})/n\mathbb{Z}$ is $\mathbb{Z}/(m\mathbb{Z} + n\mathbb{Z})$, and $m\mathbb{Z} + n\mathbb{Z} = \gcd(m, n)\mathbb{Z}$. The second is the same rule with the roles exchanged, $\mathbb{Q} \otimes \mathbb{Z}/n \simeq \mathbb{Q}/n\mathbb{Q}$, and $n\mathbb{Q} = \mathbb{Q}$. For the fourth row, if $na = 0$ write $x = ny$ in the divisible group $\mathbb{Q}_\ell/\mathbb{Z}_\ell$; then $x \otimes a = y \otimes na = 0$. The fifth row is a case of the fourth. The same argument shows $D \otimes A = 0$ whenever D is divisible and A is torsion. These rows also show that a tensor product can be much smaller than either factor, and that elements $m \otimes n$ can vanish without m or n vanishing: $1 \otimes 1 = 0$ in $\mathbb{Z}/2 \otimes \mathbb{Z}/3$.

Proposition 3.28 (right exactness)**.** *If $M' \xrightarrow{i} M \xrightarrow{p} M'' \to 0$ is exact, so is $M' \otimes N \to M \otimes N \to M'' \otimes N \to 0$. The functor $- \otimes N$ is not left exact: tensoring the injection $\mathbb{Z} \xrightarrow{2} \mathbb{Z}$ with $\mathbb{Z}/2$ gives the zero map $\mathbb{Z}/2 \to \mathbb{Z}/2$. A module N is* flat *if $- \otimes_R N$ is exact (carries injections to injections). Free modules, and more generally projective modules, are flat.*

Proof. First a criterion: a sequence $A \xrightarrow{a} B \xrightarrow{b} C \to 0$ is exact if $0 \to \mathrm{Hom}(C, P) \to \mathrm{Hom}(B, P) \to \mathrm{Hom}(A, P)$ is exact for every module P. Indeed, with $P = \operatorname{coker} b$ the projection $C \to P$ restricts to 0 on B, so it is 0, and b is surjective; with $P = C$, the image of id_C in $\mathrm{Hom}(A, C)$ is ba, which is 0 because the composite of the two maps of Hom sequences is 0; with $P = B/a(A)$, the projection $B \to P$ kills $a(A)$, so it factors through b, and $\ker b \subseteq a(A)$. By the adjunction (Theorem 3.26(iii)) the sequence $0 \to \mathrm{Hom}(M'' \otimes N, P) \to \mathrm{Hom}(M \otimes N, P) \to \mathrm{Hom}(M' \otimes N, P)$ is the sequence $0 \to \mathrm{Hom}(M'', Q) \to \mathrm{Hom}(M, Q) \to \mathrm{Hom}(M', Q)$ with $Q = \mathrm{Hom}(N, P)$, which is exact by Proposition 3.25(ii). The criterion gives right exactness. For flatness of free modules: $M \otimes R \simeq M$ naturally, so $- \otimes R$ is exact, and for $F = R^{(I)}$ the isomorphism $M \otimes F \simeq \bigoplus_{i \in I} M$ of Theorem 3.26(ii) turns $f \otimes \mathrm{id}_F$ into the map $\bigoplus f$, applied componentwise, which is injective when f is. If $F = P \oplus Q$, then $M \otimes F = (M \otimes P) \oplus (M \otimes Q)$ and $f \otimes \mathrm{id}_F = (f \otimes \mathrm{id}_P) \oplus (f \otimes \mathrm{id}_Q)$; a direct sum of two maps is injective only if each is, so $f \otimes \mathrm{id}_P$ is injective. Hence projective modules, the direct summands of free ones, are flat. □

The failure of left exactness comes from torsion: under $\mathbb{Z} \otimes \mathbb{Z}/2 \simeq \mathbb{Z}/2$ the map $2 \otimes \mathrm{id}$ sends $1 \otimes 1$ to $2 \otimes 1 = 1 \otimes 2 = 0$, so multiplication by 2, injective on $\mathbb{Z}$, becomes zero once the second factor is killed by 2. Over a principal ideal domain, flatness means exactly torsion-freeness (Proposition 3.29(ii)), which is why tensoring with $\mathbb{Z}_\ell$ or $\mathbb{Q}$ never loses information about kernels.

Proposition 3.29 (flatness)**.** *(i) For a multiplicative set $S \subseteq R$, the ring $S^{-1}R$ is a flat R-module.*

(ii) Over a principal ideal domain a module is flat if and only if it is torsion-free. Hence $\mathbb{Q}$, $\mathbb{Z}_{(\ell)}$, $\mathbb{Z}_\ell$ and $\mathbb{Q}_\ell$ are flat over $\mathbb{Z}$, and $\mathbb{Q}_\ell$ is flat over $\mathbb{Z}_\ell$.

(iii) Let $R \to S$ be flat. Then $S \otimes_R -$ commutes with kernels, images, cokernels and finite intersections of submodules. If $\mathfrak{a} = (a_1, \dots, a_k)$ is finitely generated, $M[\mathfrak{a}] \otimes_R S = (M \otimes_R S)[\mathfrak{a}S]$ inside $M \otimes_R S$. If M is finitely generated, $\mathrm{Ann}_S(M \otimes_R S) = \mathrm{Ann}_R(M)S$.

(iv) If $R \subseteq S$ are principal ideal domains with S flat over R, and $L' \subseteq L$ with L a lattice over R, then the saturation of $L' \otimes S$ in $L \otimes S$ is $\mathrm{sat}(L') \otimes S$ (Definition 3.48).

Proof. (i) By Theorem 3.38(ii) below, $S^{-1}R \otimes_R M \simeq S^{-1}M$ and $M \mapsto S^{-1}M$ is exact; that proof does not use this proposition. (ii) If N is flat and $r \neq 0$, tensoring the injection $R \xrightarrow{r} R$ with N shows that r is injective on N. Conversely let N be torsion-free. If N is finitely generated it is free (Proposition 3.46(ii)), hence flat. In general let $f\colon M' \to M$ be injective and

$z = \sum_i m'_i \otimes n_i \in M' \otimes N$ with $(f \otimes 1)(z) = 0$. In the construction of Theorem 3.26(i), this says that $\sum_i (f(m'_i), n_i)$ is a finite combination of the defining relations of $M \otimes N$; these involve finitely many elements of N. Let $N_0 \subseteq N$ be the submodule generated by them and the n_i. The same relations show that $z_0 = \sum m'_i \otimes n_i \in M' \otimes N_0$ maps to 0 in $M \otimes N_0$. As N_0 is finitely generated and torsion-free, it is flat, so $z_0 = 0$, and z, the image of z_0, is 0. (iii) Kernels, images and cokernels: tensor the exact sequences $0 \to \ker g \to M \to M''$ and $M \to M'' \to \operatorname{coker} g \to 0$ with S. Intersections: $A \cap B = \ker(M \to M/A \oplus M/B)$; after tensoring, flatness identifies $A \otimes S$ with a submodule of $M \otimes S$, right exactness identifies $(M/A) \otimes S$ with $(M \otimes S)/(A \otimes S)$, and the kernel of $M \otimes S \to (M \otimes S)/(A \otimes S) \oplus (M \otimes S)/(B \otimes S)$ is $(A \otimes S) \cap (B \otimes S)$, while by exactness it is also $(A \cap B) \otimes S$. Torsion: $M[\mathfrak{a}]$ is the kernel of $M \to M^k$, $m \mapsto (a_i m)$, and after tensoring the kernel of the same map is $(M \otimes S)[\mathfrak{a}S]$. Annihilators: for generators $m_1, \dots, m_n$, $\operatorname{Ann}_R(M)$ is the kernel of $R \to M^n$, $r \mapsto (rm_i)$, and after tensoring the kernel of $S \to (M \otimes S)^n$ is $\operatorname{Ann}_S(M \otimes S)$, because the $m_i \otimes 1$ generate $M \otimes S$ over S. (iv) Write $L/L' \simeq F \oplus C$ with F free and C torsion (Theorem 3.43); then $\operatorname{sat}(L')$ is the kernel of $L \to L/L' \to F$. After tensoring, $\operatorname{sat}(L') \otimes S$ is the kernel of $L \otimes S \to F \otimes S$, a free target, so it is saturated in $L \otimes S$; it contains $L' \otimes S$ with quotient $C \otimes S$, which is killed by the nonzero element of R killing C, hence torsion. A saturated submodule containing $L' \otimes S$ with torsion quotient is its saturation (Proposition 3.49). □

In the paper 3.30. "The same statements hold with $\mathbb{Z}$ replaced by $\mathbb{Z}_\ell$ and r by its ℓ-part" (Lemma lem:crit) and "Every step holds verbatim over $\mathbb{Z}_\ell$" (the end of its proof) are Proposition 3.29: $\mathbb{Z}_\ell$ is flat over $\mathbb{Z}$, so $\ker \phi_f \otimes \mathbb{Z}_\ell$ is the kernel of $\phi_f \otimes \mathbb{Z}_\ell$, the annihilator $\operatorname{Ann}_{\mathbb{T}}(\ker \phi_f) \otimes \mathbb{Z}_\ell$ is the annihilator in $\mathbb{T} \otimes \mathbb{Z}_\ell$, and the congruence ideal $\phi_f(\operatorname{Ann}_{\mathbb{T}} \ker \phi_f)$ becomes $\phi_f(\operatorname{Ann}_{\mathbb{T}} \ker \phi_f)\mathbb{Z}_\ell$, whose generator is the ℓ-part of r. The same proposition is used in Lemma lem:step1 and in the proof of Theorem thm:quant, which work over $\mathbb{Z}_\ell$ from the start.

3.4 Noetherian rings, Nakayama's lemma, local rings and localisation

Every ring in the paper is Noetherian: $\mathbb{Z}$, $\mathbb{Z}_\ell$, the Hecke algebra $\mathbb{T}$ (a finitely generated $\mathbb{Z}$-module) and its completions $\mathbb{T}_{\mathfrak{m}}$. Nakayama's lemma enters the paper twice: in Remark rem:free, where the two-dimensionality of $J_0(N)[\mathfrak{m}]$ gives two generators of the Tate module over $\mathbb{T}_{\mathfrak{m}}$ (Theorem 3.116), and in Lemma lem:h0, by name, where a homomorphism $T/\ell^k \to (T/\ell^k)(1)$ that is nonzero modulo ℓ is an isomorphism. Local rings and localisation give the meaning of $\mathbb{T}_{\mathfrak{m}}$.

Proposition 3.31 (Noetherian modules)**.** *(i) For an R-module M the following are equivalent: every ascending chain of submodules is eventually constant; every nonempty set of submodules has a maximal element; every submodule is finitely generated. Such M is* Noetherian*; R is a Noetherian ring if it is Noetherian as an R-module, that is, if every ideal is finitely generated.*

(ii) Submodules and quotients of Noetherian modules are Noetherian, and if $0 \to M' \to M \to M'' \to 0$ is exact with M', M'' Noetherian then M is Noetherian. Over a Noetherian ring every finitely generated module is Noetherian; hence submodules of finitely generated modules are finitely generated, and finitely generated modules are finitely presented.

(iii) In a nonzero Noetherian ring every proper ideal is contained in a maximal ideal.

(iv) (Hilbert's basis theorem.) If R is Noetherian, so is $R[x]$.

(v) *Fields, principal ideal domains, $\mathbb{Z}_\ell$ (Theorem 3.58), and every ring that is finitely generated as a module over a Noetherian ring (such as the Hecke algebra $\mathbb{T}$ over $\mathbb{Z}$, or $\mathbb{T}\otimes\mathbb{Z}_\ell$ over $\mathbb{Z}_\ell$) are Noetherian.*

Proof. (i) If chains stabilise and a nonempty set Σ of submodules had no maximal element, we could choose a strictly increasing infinite chain in Σ. If maximal elements exist and $N \subseteq M$, a maximal element of the set of finitely generated submodules of N is N itself (otherwise add an element of N outside it). If every submodule is finitely generated and $N_1 \subseteq N_2 \subseteq \cdots$, then $\bigcup N_i$ is generated by finitely many elements, all in some N_k, so the chain is constant from k on. (ii) Submodules: by the third condition. Quotients: by the first, via Theorem 3.8(iii). Extensions: if $N_1 \subseteq N_2 \subseteq \cdots$ in M, both $N_i \cap M'$ and the images of N_i in M'' stabilise, and then so does N_i (if $N \subseteq N'$ have the same intersection with M' and the same image in M'', then $N = N'$: for $x \in N'$ choose $y \in N$ with the same image in M''; then $x - y \in N' \cap M' = N \cap M'$, so $x \in N$). By induction R^n is Noetherian, and a finitely generated module is a quotient of some R^n. The kernel of $R^n \twoheadrightarrow M$ is then finitely generated. (iii) The set of proper ideals containing a given proper ideal is nonempty and has a maximal element by (i), which is a maximal ideal. (iv) We do not prove this; see [7, Theorem 7.5] (number not verified against the printed edition). (v) Fields and principal ideal domains: every ideal is generated by one element. A ring A finite over a Noetherian R is a Noetherian R-module by (ii), and its ideals are R-submodules. □

Lemma 3.32 (the determinant trick)**.** *Let M be generated by n elements, $\mathfrak{a} \subseteq R$ an ideal and $\phi \in \mathrm{End}_R(M)$ with $\phi(M) \subseteq \mathfrak{a}M$. Then $\phi^n + a_1\phi^{n-1} + \cdots + a_n = 0$ in $\mathrm{End}_R(M)$ for some $a_i \in \mathfrak{a}^i$. Consequently:*

(a) if M is finitely generated and $\mathfrak{a}M = M$, there is $x \in R$ with $x \equiv 1 \pmod{\mathfrak{a}}$ and $xM = 0$;

(b) a surjective endomorphism of a finitely generated module is an isomorphism.

Proof. Let $m_1, \ldots, m_n$ generate M and write $\phi(m_i) = \sum_j a_{ij} m_j$ with $a_{ij} \in \mathfrak{a}$. Work in the commutative ring $R[\phi] \subseteq \mathrm{End}_R(M)$ and let $B = (\delta_{ij}\phi - a_{ij})$, a matrix over it. Then B applied to the column (m_j) is 0. Multiplying by the adjugate of B gives $\det(B)m_j = 0$ for all j, so $\det B = 0$ in $\mathrm{End}_R(M)$. Expanding $\det(\delta_{ij}\phi - a_{ij})$ as a sum over permutations, each term is a product of n entries; multiplying out the diagonal entries $\phi - a_{jj}$, every resulting monomial is $\pm\phi^{n-i}$ times a product of i entries a_{jk}; so the coefficient a_i of ϕ^{n-i} is a sum of products of i elements of $\mathfrak{a}$, which lies in $\mathfrak{a}^i$, and the coefficient of ϕ^n is 1 (from the identity permutation only). This is the stated polynomial; it is the characteristic polynomial of the matrix (a_{ij}), evaluated at ϕ, and for $M = R^n$ free it is Cayley-Hamilton. (a) Take $\phi = \mathrm{id}$, which maps M into $\mathfrak{a}M = M$: then $x = 1 + a_1 + \cdots + a_n$ kills M, and $x \equiv 1 \pmod{\mathfrak{a}}$. (b) Let ϕ be surjective and regard M as an $R[X]$-module, X acting as ϕ; it is finitely generated over $R[X]$ (by the same generators), and $(X)M = \phi(M) = M$. By (a) over the ring $R[X]$ with the ideal (X) there is $x \equiv 1 \pmod{X}$, that is, $x = 1 - Xg(X)$ with $g \in R[X]$, with $xM = 0$; that is, $\phi \circ g(\phi) = \mathrm{id}$. If $\phi(m) = 0$ then $m = g(\phi)\phi(m) = 0$ (the two commute); so ϕ is injective. □

Definition 3.33 (local rings)**.** A ring is *local* if it has exactly one maximal ideal $\mathfrak{m}$; we write $(R, \mathfrak{m}, k)$ with $k = R/\mathfrak{m}$ the *residue field*. The *Jacobson radical* $\mathfrak{J}(R)$ is the intersection of all maximal ideals.

Proposition 3.34. *(i) R is local if and only if its non-units form an ideal; then this ideal is $\mathfrak{m}$, and $R^\times = R \setminus \mathfrak{m}$.*

(ii) *If $x \in \mathfrak{J}(R)$ then $1+x$ is a unit.*

(iii) *Examples of local rings: fields; $\mathbb{Z}_{(p)}$ (Chapter 2); discrete valuation rings (Theorem 3.55); $\mathbb{Z}/p^n$; $k[x]/(x^2)$; $\mathbb{Z}_\ell[x]/(x^2)$; each factor $\mathbb{T}_\mathfrak{m}$ of a finite free $\mathbb{Z}_\ell$-algebra (Theorem 3.95). Non-examples: $\mathbb{Z}$; $\mathbb{Z}_\ell \times \mathbb{Z}_\ell$ (maximal ideals $\ell\mathbb{Z}_\ell \times \mathbb{Z}_\ell$ and $\mathbb{Z}_\ell \times \ell\mathbb{Z}_\ell$); $\mathbb{Z}_{(11)}[x]/(x^2+x-1)$, which has two maximal ideals (Theorem 3.95(v)).*

Proof. (i) A non-unit x generates a proper ideal, which lies in a maximal ideal (Chapter 2, by Zorn's lemma; or Proposition 3.31(iii)). If R is local this ideal is $\mathfrak{m}$, so the non-units are exactly $\mathfrak{m}$. Conversely if the non-units form an ideal $\mathfrak{n}$, every proper ideal consists of non-units and lies in $\mathfrak{n}$, which is therefore the unique maximal ideal. (ii) If $1+x$ were not a unit it would lie in a maximal ideal $\mathfrak{m}'$; so would x, and then $1 \in \mathfrak{m}'$. (iii) In $\mathbb{Z}/p^n$ an integer prime to p is invertible modulo p^n, and a multiple of p is nilpotent, so the non-units are the multiples of p. In $k[x]/(x^2)$ and $\mathbb{Z}_\ell[x]/(x^2)$ write an element as $a+bx$; then $(a+bx)(a-bx) = a^2$, so $a+bx$ is a unit as soon as a is a unit of k, respectively of $\mathbb{Z}_\ell$, while if $a = 0$ in k (respectively $a \in \ell\mathbb{Z}_\ell$) the element lies in the proper ideal (x) (respectively (ℓ, x), with quotient $\mathbb{F}_\ell$). So the non-units are the multiples of x, respectively the ideal (ℓ, x); these form ideals. The others are proved where cited. □

The elements of the Jacobson radical are the "small" elements of R: in a local ring $\mathfrak{J}(R) = \mathfrak{m}$, and (ii) is the algebraic shadow of the geometric series $1/(1+x) = 1 - x + x^2 - \cdots$. In $\mathbb{Z}_\ell$, for example, $1+\ell y$ is a unit for every $y \in \mathbb{Z}_\ell$. Nakayama's lemma, next, exploits exactly this.

Theorem 3.35 (Nakayama's lemma)**.** *Let $(R, \mathfrak{m}, k)$ be a local ring and M a finitely generated R-module.*

(i) *If $\mathfrak{m}M = M$ then $M = 0$. More generally, for any ring R and any ideal $\mathfrak{a} \subseteq \mathfrak{J}(R)$, $\mathfrak{a}M = M$ implies $M = 0$.*

(ii) *If $N \subseteq M$ is a submodule with $N + \mathfrak{m}M = M$, then $N = M$.*

(iii) *Elements $x_1, \dots, x_r$ generate M if and only if their images span the k-vector space $M/\mathfrak{m}M$. The minimal number of generators of M is $\dim_k M/\mathfrak{m}M$.*

(iv) *A homomorphism $f\colon N' \to M$ is surjective if and only if $f \otimes k\colon N'/\mathfrak{m}N' \to M/\mathfrak{m}M$ is. A matrix in $\mathrm{M}_n(R)$ is invertible if and only if its reduction modulo $\mathfrak{m}$ is; an endomorphism of R^n is an automorphism if and only if it is so modulo $\mathfrak{m}$.*

(v) *Every finitely generated projective R-module is free.*

Proof. (i) By Lemma 3.32(a) some $x = 1+a$ with $a \in \mathfrak{a}$ kills M; x is a unit by Proposition 3.34(ii), so $M = 0$. (In a local ring $\mathfrak{J}(R) = \mathfrak{m}$, so the two forms of (i) agree.) (ii) The quotient M/N is finitely generated, and $\mathfrak{m}(M/N) = (\mathfrak{m}M + N)/N = M/N$; by (i), $M/N = 0$. (iii) Apply (ii) to $N = \sum Rx_i$; conversely generators of M span $M/\mathfrak{m}M$. A minimal generating set therefore has $\dim_k M/\mathfrak{m}M$ elements. (iv) The first statement is (ii) for $N = f(N')$. A matrix is invertible iff its determinant is a unit (Proposition 3.21(iii)), iff the determinant is not in $\mathfrak{m}$, iff the reduced determinant is nonzero. (v) Let P be finitely generated projective and $n = \dim_k P/\mathfrak{m}P$. By (iii) there is a surjection $R^n \twoheadrightarrow P$; it splits, so $R^n \simeq P \oplus Q$ with Q finitely generated (a quotient of R^n). Reducing modulo $\mathfrak{m}$ gives $k^n \simeq P/\mathfrak{m}P \oplus Q/\mathfrak{m}Q$, so $Q/\mathfrak{m}Q = 0$ and $Q = 0$ by (i). □

Example 3.36. A finitely generated $\mathbb{Z}_\ell$-module M with $M/\ell M \simeq \mathbb{F}_\ell^2$ is generated by two elements. An endomorphism of $(\mathbb{Z}/\ell^k)^n$ whose reduction modulo ℓ is invertible is invertible (apply (iv) over the local ring $\mathbb{Z}/\ell^k$).

The hypothesis "finitely generated" cannot be dropped: $\mathbb{Q}$ is a module over the local ring $\mathbb{Z}_{(p)}$ with $p\mathbb{Q}=\mathbb{Q}$, and $\mathbb{Q}\neq 0$. In (iii) the point is that one reduction suffices: over $\mathbb{Z}_\ell$, to know that M is cyclic it is enough to know that $M/\ell M$ is a line, while over $\mathbb{Z}$ one would have to look at M/pM for every prime p (and over a general ring even that is not enough). This is how the two-dimensionality of $J_0(N)[\mathfrak{m}]$ in Remark rem:free yields two generators (Paper link 3.37).

In the paper 3.37. In the proof of Lemma lem:h0 the paper writes: "An element of exact order ℓ^k is a map $\phi\colon T/\ell^k \to (T/\ell^k)(1)$ whose reduction modulo ℓ is nonzero, hence an isomorphism, so ϕ is an isomorphism by Nakayama's lemma". The underlying module map is an endomorphism of $(\mathbb{Z}/\ell^k)^2$ (the twist does not change the module), invertible modulo ℓ because a nonzero $G_{\mathbb{Q}}$-map between irreducible representations is an isomorphism, its kernel and image being subrepresentations (Chapter 4); it is therefore invertible by Example 3.36. In Remark rem:free, the two-dimensionality of $J_0(N)[\mathfrak{m}]$ is turned into two generators by Theorem 3.35(iii); see Theorem 3.116.

Theorem 3.38 (localisation)**.** *Let $S\subseteq R$ be multiplicative ($1\in S$, $SS\subseteq S$). Let $S^{-1}M$ be the set of fractions m/s ($m\in M$, $s\in S$), where $m/s=m'/s'$ if and only if $u(s'm-sm')=0$ for some $u\in S$; with the evident operations $S^{-1}R$ is a ring and $S^{-1}M$ an $S^{-1}R$-module.*

(i) The map $R\to S^{-1}R$, $r\mapsto r/1$, sends S to units, and every ring homomorphism $R\to A$ sending S to units factors uniquely through it.

(ii) $S^{-1}R\otimes_R M\simeq S^{-1}M$, $(a/s)\otimes m\mapsto am/s$, and $M\mapsto S^{-1}M$ is exact.

(iii) $\mathfrak{b}\mapsto \mathfrak{b}\cap R$ (preimage) and $\mathfrak{p}\mapsto S^{-1}\mathfrak{p}$ are inverse bijections between the prime ideals of $S^{-1}R$ and the prime ideals of R not meeting S.

(iv) For a prime $\mathfrak{p}$, $R_{\mathfrak{p}}=(R\setminus\mathfrak{p})^{-1}R$ is local with maximal ideal $\mathfrak{p}R_{\mathfrak{p}}$; we write $M_{\mathfrak{p}}$ for the localised module.

(v) $M=0$ if and only if $M_{\mathfrak{m}}=0$ for every maximal ideal $\mathfrak{m}$; a homomorphism is injective (surjective) if and only if it is so after localising at every maximal ideal.

(vi) Localisation commutes with finite direct sums, quotients, and annihilators of finitely generated modules: $S^{-1}\operatorname{Ann}_R(M)=\operatorname{Ann}_{S^{-1}R}(S^{-1}M)$. It commutes with Hom *out of finitely presented modules (stated; see [7, Chapter 3]).*

(vii) Examples: $\mathbb{Z}_{(p)}$; $\mathbb{Q}=\mathbb{Z}_{(0)}$; $\mathbb{Z}[1/\ell]$; $(\mathbb{Z}/n)_{(p)}\simeq\mathbb{Z}/p^{v_p(n)}$; for $R=R_1\times R_2$ and the prime $\mathfrak{p}=\mathfrak{p}_1\times R_2$, $R_{\mathfrak{p}}\simeq(R_1)_{\mathfrak{p}_1}$.

Proof. The relation is an equivalence relation. Reflexivity and symmetry are clear. For transitivity, let $u(s'm-sm')=0$ and $u'(s''m'-s'm'')=0$. Multiply the first by $u's''$ and the second by us and add: the terms in m' cancel and $uu's'(s''m-sm'')=0$, with $uu's'\in S$. (The factor u cannot be omitted: without it the relation need not be transitive when M has elements killed by elements of S.) The operations $m/s+m'/s'=(s'm+sm')/ss'$ and $(r/t)(m/s)=rm/ts$ are well defined by computations of the same kind. (i) $s/1$ has inverse $1/s$. If $\phi\colon R\to A$ inverts S, put $\psi(r/s)=\phi(r)\phi(s)^{-1}$; if $u(s'r-sr')=0$ then $\phi(u)$ is a unit and $\phi(r)\phi(s)^{-1}=\phi(r')\phi(s')^{-1}$. Uniqueness is forced by $\psi(r/s)\psi(s/1)=\psi(r/1)$. (ii) The bilinear map $(a/s,m)\mapsto am/s$ gives $\alpha\colon S^{-1}R\otimes M\to S^{-1}M$. Every element of $S^{-1}R\otimes M$ has the form $(1/s)\otimes m$ (bring the finitely many fractions to a common denominator). Define $\beta(m/s)=(1/s)\otimes m$; it is well defined: if $u(s'm-sm')=0$ then $(1/s)\otimes m=(us'/uss')\otimes m=(1/uss')\otimes us'm=$

$(1/uss')\otimes usm' = (1/s')\otimes m'$. The two composites are identities: $\alpha\beta(m/s) = \alpha((1/s)\otimes m) = m/s$, and $\beta\alpha((a/s)\otimes m) = \beta(am/s) = (1/s)\otimes am = (a/s)\otimes m$. Exactness: let $M' \xrightarrow{f} M \xrightarrow{g} M''$ be exact at M and $g(m)/s = 0$. Then $ug(m) = 0$ for some $u \in S$, so $um = f(m')$ and $m/s = f(m')/us$. (iii) If $\mathfrak{b}$ is prime in $S^{-1}R$, its preimage is prime and misses S (it contains no unit), and $\mathfrak{b} = S^{-1}(\mathfrak{b}\cap R)$ because $r/s \in \mathfrak{b}$ iff $r/1 \in \mathfrak{b}$. If $\mathfrak{p}$ is prime with $\mathfrak{p}\cap S = \emptyset$, then $S^{-1}\mathfrak{p}$ is a proper ideal, it is prime (if $(a/s)(b/t) \in S^{-1}\mathfrak{p}$ then $uab \in \mathfrak{p}$ for some $u \in S$, and $u \notin \mathfrak{p}$), and its preimage is $\mathfrak{p}$ (if $r/1 = p/s$ then $u(sr-p) = 0$, so $usr \in \mathfrak{p}$ and $r \in \mathfrak{p}$). (iv) By (iii) the primes of $R_{\mathfrak{p}}$ correspond to the primes contained in $\mathfrak{p}$, so $\mathfrak{p}R_{\mathfrak{p}}$ is the unique maximal ideal. (v) If $0 \neq m \in M$, then $\operatorname{Ann}(m)$ is proper and lies in a maximal ideal $\mathfrak{m}$; then $m/1 \neq 0$ in $M_{\mathfrak{m}}$, since $um = 0$ would put $u \in \operatorname{Ann}(m) \subseteq \mathfrak{m}$. Apply this to kernels and cokernels, which commute with localisation by (ii). (vi) Direct sums and quotients: by (ii) and Theorem 3.26(ii). Annihilators: $S^{-1}R$ is flat by (ii), so Proposition 3.29(iii) applies. (vii) The first three are the definitions (with $S = \mathbb{Z}\setminus p\mathbb{Z}$, $\mathbb{Z}\setminus\{0\}$, $\{\ell^k\}$). For $\mathbb{Z}/n = \mathbb{Z}/p^a \times \mathbb{Z}/m$ with $p \nmid m$: m is a unit of $\mathbb{Z}_{(p)}$ and kills $\mathbb{Z}/m$, so $(\mathbb{Z}/m)_{(p)} = 0$, while every element of $\mathbb{Z}\setminus p\mathbb{Z}$ acts invertibly on $\mathbb{Z}/p^a$. For the product, $(1,0) \notin \mathfrak{p}$ becomes a unit in $R_{\mathfrak{p}}$ and $(1,0)(0,1) = 0$, so $(0,1) = 0$ in $R_{\mathfrak{p}}$, and $R_{\mathfrak{p}} = (R_1 \times 0)_{\mathfrak{p}} \simeq (R_1)_{\mathfrak{p}_1}$. □

Remark 3.39. The last example of (vii) is the reason why, for a finite algebra over a *complete* discrete valuation ring, the localisation at a maximal ideal is a direct factor (Theorem 3.95): completeness produces the decomposition into a product, and localisation then picks out one factor. Without completeness there is in general no such decomposition (Theorem 3.95(v)), which is why the paper always works with $\mathbb{T}\otimes\mathbb{Z}_\ell$ (Convention 3.2).

With the general machinery of exactness, tensor products, Nakayama and localisation in place, the next section specialises to principal ideal domains, where finitely generated modules can be classified completely. That classification is what turns statements about lattices of modular forms into statements about integers: indices, invariant factors and congruence moduli.

3.5 Finitely generated modules over a principal ideal domain; lattices and saturation

All the lattices of the paper live over the principal ideal domains $\mathbb{Z}$ and $\mathbb{Z}_\ell$: $S_2(\Gamma_0(N);\mathbb{Z})$ and its sublattices $\mathbb{Z}f$ and $L = f^\perp \cap S_2(\Gamma_0(N);\mathbb{Z})$ in Lemma lem:crit; T_3E in Lemma lem:IV; the lattice L and its saturated sublattices $L[\wp]$, $L[I]$ in Lemma lem:ddt417; the module $H^1(I,M) \simeq (\mathbb{Z}_\ell/n')^2 \oplus \mathbb{Z}_\ell$ in Lemma lem:tamfactor. This section proves the structure theorem through the Smith normal form, introduces saturation, and ends with the two results that carry the second paragraph of the proof of Lemma lem:crit: the dual of an inclusion of lattices (Proposition 3.51) and the congruence module of a decomposition (Proposition 3.53). Throughout, R is a principal ideal domain with fraction field K.

Theorem 3.40 (submodules of free modules)**.** *A submodule of a free R-module of rank n is free of rank at most n. Consequently finitely generated R-modules are finitely presented, and finitely generated projective R-modules are free.*

Proof. Induction on n, the case $n = 0$ being trivial. Let $N \subseteq R^n$ and let $\pi_n\colon R^n \to R$ be the last coordinate. Then $\pi_n(N)$ is an ideal, aR say. If $a = 0$, $N \subseteq R^{n-1}$ and we are done. Otherwise choose $x \in N$ with $\pi_n(x) = a$. Then $N = (N \cap R^{n-1}) \oplus Rx$: every $y \in N$ has $\pi_n(y) = ra$, and $y - rx \in N \cap R^{n-1}$; the sum is direct because $\pi_n(rx) = ra = 0$ forces $r = 0$ in the domain R. By induction $N \cap R^{n-1}$ is free of rank at most $n-1$, and $Rx \simeq R$. The consequences: the kernel of

$R^n \twoheadrightarrow M$ is free of finite rank, and a projective module is a direct summand, hence a submodule, of a free module. □

Theorem 3.41 (Smith normal form)**.** *For $A \in \mathrm{M}_{m\times n}(R)$ there are $U \in \mathrm{GL}_m(R)$ and $V \in \mathrm{GL}_n(R)$ such that UAV is the matrix with diagonal entries $d_1, \dots, d_s, 0, \dots, 0$ and zeros elsewhere, where $d_i \neq 0$ and $d_1 \mid d_2 \mid \cdots \mid d_s$. For each k the ideal $D_k(A)$ generated by the $k \times k$ minors of A (the k-th* determinantal ideal*) satisfies $D_k(UAV) = D_k(A)$; hence $D_k(A) = (d_1 \cdots d_k)$ for $k \leq s$ and 0 for $k > s$, and the ideals (d_i), the* invariant factors *of A, are uniquely determined.*

Proof. For $a \neq 0$ let $\lambda(a)$ be the number of prime factors of a counted with multiplicity (R is a unique factorisation domain, Chapter 2); units have $\lambda = 0$. We use row and column operations by invertible matrices: permutations, adding a multiple of one row (column) to another, and the following *Bezout operation*: if $g = \gcd(a, b) = xa + yb$ with a, b not both 0, then $\begin{pmatrix} x & y \\ -b/g & a/g \end{pmatrix}$ has determinant 1 and sends the column $(a, b)^{\mathsf{T}}$ to $(g, 0)^{\mathsf{T}}$; acting on two rows (or, transposed, on two columns) it replaces a by g. If $A = 0$ there is nothing to do. Otherwise move a nonzero entry with λ minimal to position $(1, 1)$; call it a. If a does not divide some entry b of the first column, the Bezout operation on the two rows replaces a by g with $\lambda(g) < \lambda(a)$; similarly for the first row. Since λ cannot decrease forever, after finitely many steps a divides every entry of the first row and column, which we clear by elementary operations. Now $A = \mathrm{diag}(a, A')$. If a does not divide an entry b of A', add the row of b to the first row: the first row now contains b, and the previous step lowers $\lambda(a)$ again. Eventually a divides every entry of A', and this persists under operations on A', whose entries are combinations of the old ones. Induction on the size finishes the existence, with $d_1 = a$. For invariance: each $k \times k$ minor of UA is an R-combination of $k \times k$ minors of A (Cauchy-Binet, or expand the rows of UA as combinations of rows of A by multilinearity), so $D_k(UA) \subseteq D_k(A)$, and equality follows by applying the same to U^{-1}; columns likewise. For a diagonal matrix with $d_1 \mid \cdots \mid d_s$ the nonzero $k \times k$ minors are products of k of the d_i, all divisible by $d_1 \cdots d_k$. Hence $(d_1 \cdots d_k)$ is determined by A, and so is $(d_k) = (d_1 \cdots d_k)/(d_1 \cdots d_{k-1})$. □

Example 3.42. Computed by hand and checked with PARI's `matsnf`, over $\mathbb{Z}$: $\begin{pmatrix} 2 & 4 \\ 6 & 8 \end{pmatrix} \sim \mathrm{diag}(2, 4)$; the relation matrix with rows $(2, 4, 4)$, $(-6, 6, 12)$, $(10, -4, -16)$ (from [58, Section 12.1]) $\sim \mathrm{diag}(2, 6, 12)$; $\begin{pmatrix} 3 & 6 \\ 9 & 3 \end{pmatrix} \sim \mathrm{diag}(3, 15)$ (its determinant is -45); the 3×2 matrix with rows $(6, 0)$, $(0, 4)$, $(2, 2) \sim \mathrm{diag}(2, 2)$ (the gcd of its entries is 2 and its 2×2 minors are 24, 12, -8, with gcd 4). Over $\mathbb{Z}_3$ the matrix $\begin{pmatrix} 3 & 6 \\ 9 & 3 \end{pmatrix}$ is equivalent to $\mathrm{diag}(3, 3)$, since $15 = 3 \cdot 5$ and $5 \in \mathbb{Z}_3^{\times}$.

```
matsnf([2,4;6,8])                    \\ [4, 2]
matsnf([2,4,4;-6,6,12;10,-4,-16])    \\ [12, 6, 2]
matsnf([3,6;9,3])                    \\ [15, 3]
matsnf([6,0,2;0,4,2])                \\ [2, 2] (transpose of the 3x2 matrix)
```

PARI lists the invariant factors in decreasing order. Transposing a matrix does not change its invariant factors, since A and A^{T} have the same $k \times k$ minors; so it does not matter that the book writes relations as rows (Convention 3.1(g)). By hand, for the first matrix: subtracting 3 times the first row from the second gives rows $(2, 4)$, $(0, -4)$; subtracting 2 times the first column from the second gives $\mathrm{diag}(2, -4)$; changing the sign of the second row gives $\mathrm{diag}(2, 4)$. The

invariance statement checks this: the gcd of the entries $2,4,6,8$ is $2=d_1$, and the determinant -8 gives $d_1d_2=8$ up to sign, so $d_2=4$.

Theorem 3.43 (structure of finitely generated modules over a principal ideal domain)**.** *Let M be a finitely generated R-module.*

(i) (Invariant factors.) $M\simeq R^r\oplus R/(d_1)\oplus\cdots\oplus R/(d_s)$ with d_i nonzero non-units and $d_1\mid\cdots\mid d_s$; the integer r and the ideals (d_i) are uniquely determined.

(ii) (Elementary divisors.) $M\simeq R^r\oplus\bigoplus_j R/(p_j^{a_j})$ with p_j primes and $a_j\geq 1$; the multiset of the ideals $(p_j^{a_j})$ is uniquely determined.

(iii) Special cases: for $R=\mathbb{Z}$ this is the structure of finitely generated abelian groups (for finite groups, Chapter 1); for a discrete valuation ring, $M\simeq\mathcal{O}^r\oplus\bigoplus_i\mathcal{O}/\varpi^{a_i}$ (Proposition 3.57); for $R=F[x]$ and M a finite-dimensional vector space with an endomorphism, the rational canonical form, and over an algebraically closed F the Jordan form.

Proof. Existence. By Theorem 3.40 there is a presentation $R^m\xrightarrow{A}R^n\to M\to 0$. Replacing A by UAV changes the basis of the relations by U and the basis of R^n by V^{-1}, so $M\simeq R^n/(\text{row space of }UAV)$. For $UAV=\operatorname{diag}(d_1,\dots,d_s,0,\dots)$ this is $\bigoplus_{i\leq s}R/(d_i)\oplus R^{n-s}$; drop the summands with d_i a unit. (ii) follows from (i) by the Chinese remainder theorem $R/(d)\simeq\bigoplus_p R/(p^{v_p(d)})$ (Chapter 2). *Uniqueness.* The torsion submodule M_{tor} (Definition 3.45) is intrinsic, and $M/M_{\mathrm{tor}}\simeq R^r$, so $r=\dim_K(M\otimes K)$ is determined. For a prime p the p-primary part $M(p)=M_{\mathrm{tor}}[p^\infty]$ is intrinsic and is the sum of the summands $R/(p^{a_j})$ with $p_j=p$ (up to units). Since $p^kR/(p^a)/p^{k+1}R/(p^a)$ is $R/(p)$ if $k<a$ and 0 otherwise, $\dim_{R/(p)}(p^kM(p)/p^{k+1}M(p))=\#\{j:p_j=p,\ a_j>k\}$, and these numbers determine the exponents a_j belonging to p. So the elementary divisors are unique, and the invariant factors, which are recovered from them (d_s is the product of the largest prime powers for each prime, d_{s-1} of the next ones, and so on), are unique too. □

Example 3.44. The abelian group with relation rows $(2,4,4)$, $(-6,6,12)$, $(10,-4,-16)$ is $\mathbb{Z}/2\oplus\mathbb{Z}/6\oplus\mathbb{Z}/12$ by Example 3.42; its elementary divisors are $2,2,4$ and $3,3$, that is, it is $\mathbb{Z}/2\oplus\mathbb{Z}/2\oplus\mathbb{Z}/4\oplus\mathbb{Z}/3\oplus\mathbb{Z}/3$.

The uniqueness proof can be watched at work on $M=\mathbb{Z}/2\oplus\mathbb{Z}/4$ and $p=2$: $\dim_{\mathbb{F}_2}M/2M=2$ (both summands have exponent ≥ 1), $\dim_{\mathbb{F}_2}2M/4M=1$ (only $\mathbb{Z}/4$ has exponent ≥ 2), and $\dim_{\mathbb{F}_2}4M/8M=0$. So exactly two exponents are ≥ 1 and one is ≥ 2, which forces the exponents 1 and 2; no rearrangement such as $\mathbb{Z}/8$ or $(\mathbb{Z}/2)^3$ gives the same numbers.

Definition 3.45 (torsion)**.** Let R be a domain with fraction field K. An element $m\in M$ is *torsion* if $rm=0$ for some $r\neq 0$. The torsion elements form a submodule M_{tor}; M is *torsion-free* if $M_{\mathrm{tor}}=0$ and *torsion* if $M_{\mathrm{tor}}=M$. The *rank* of M is $\operatorname{rank}M=\dim_K(M\otimes_R K)$.

Proposition 3.46. *(i) M_{tor} is the kernel of $M\to M\otimes_R K$, $m\mapsto m\otimes 1$, and M/M_{tor} is torsion-free.*

(ii) Over a principal ideal domain a finitely generated torsion-free module is free, and $M\simeq M_{\mathrm{tor}}\oplus M/M_{\mathrm{tor}}$ for every finitely generated M (the splitting is not canonical).

(iii) Let $R\subseteq R'$ be domains with R' a principal ideal domain that is free of rank e as an R-module. A finitely generated R'-module X that is torsion-free over R, of R-rank n, is free over R' of rank n/e. For instance, $\mathbb{Z}_3[\zeta_3]$ is free of rank 2 over $\mathbb{Z}_3$, with basis $1,\zeta_3$.

Proof. (i) $M \otimes K = S^{-1}M$ with $S = R \setminus \{0\}$ (Theorem 3.38(ii)), and $m/1 = 0$ iff $um = 0$ for some $u \neq 0$. If $rm \in M_{\text{tor}}$ with $r \neq 0$, then $r'rm = 0$ with $r' \neq 0$, so $m \in M_{\text{tor}}$. (ii) By Theorem 3.43, a finitely generated torsion-free module has no summands $R/(d_i)$; and M/M_{tor} is free, so $M \twoheadrightarrow M/M_{\text{tor}}$ splits (Proposition 3.23). (iii) First, X is torsion-free over R'. Let $0 \neq r' \in R'$ and let μ be multiplication by r' on $R' \simeq R^e$; it is injective (R' is a domain), so $\delta = \det \mu \neq 0$ (it is injective on $R' \otimes K \simeq K^e$, hence invertible there). By Cayley-Hamilton, $\mu^e + c_1\mu^{e-1} + \cdots + c_e = 0$ with $c_e = \pm\delta$, so $\delta = r'y$ for some $y \in R'$. If $r'x = 0$ then $\delta x = 0$ with $0 \neq \delta \in R$, so $x = 0$. By (ii) over the principal ideal domain R', $X \simeq R'^m$, which is free of rank me over R; so $n = me$. □

In the paper 3.47. The paragraph after the proof of Lemma lem:IV says that "T_3E is a torsion-free module of $\mathbb{Z}_3$-rank 2 over the discrete valuation ring $\mathbb{Z}_3[X]/(X^2+X+1) \simeq \mathbb{Z}_3[\zeta_3]$, with X acting as σ, hence free of rank one over it". Apply Proposition 3.46(iii) with $R = \mathbb{Z}_3$, $R' = \mathbb{Z}_3[\zeta_3]$ (a discrete valuation ring, hence a principal ideal domain, by Chapter 6), $e = 2$, and $X = T_3E$, which is a free $\mathbb{Z}_3$-module of rank 2 and an R'-module through σ (Example 3.7(c)): it is free of rank $2/2 = 1$ over R'. Lemma lem:tamadd uses the same statement. Exercise 3.120 works out the consequences for $T/3T$.

Definition 3.48 (saturation)**.** Let M be a lattice and $L \subseteq M$ a submodule. L is *saturated* in M if M/L is torsion-free. The *saturation* of L is $\text{sat}(L) = M \cap KL$, computed inside $M \otimes K$ (where KL is the K-span of L).

The definition separates two ways in which a sublattice can be "small". A sublattice of smaller rank, such as $L = \mathbb{Z}(1,1) \subset \mathbb{Z}^2$, misses whole directions; a sublattice such as $\mathbb{Z}(2,2)$ misses in addition the points $(1,1)$ that lie on its own line. Saturation adds back exactly these points: $\text{sat}(\mathbb{Z}(2,2)) = \mathbb{Z}^2 \cap \mathbb{Q}(1,1) = \mathbb{Z}(1,1)$. The submodules that occur naturally in the paper, such as the forms killed by an ideal of the Hecke algebra or the lattice of forms orthogonal to f, are cut out by linear conditions and are automatically saturated (Proposition 3.49(iii)); a non-saturated sublattice would encode a congruence that is not visible in its own span, and the index $[\text{sat}(L) : L]$ measures it.

Proposition 3.49. *Let M be a lattice and $L \subseteq M$ a submodule.*

(i) The following are equivalent: (a) L is saturated; (b) $L = M \cap KL$; (c) L is a direct summand of M; and, when $R = \mathcal{O}$ is a discrete valuation ring, (d) $L \cap \varpi M = \varpi L$, that is, $L/\varpi L \to M/\varpi M$ is injective.

(ii) $\text{sat}(L)$ is the smallest saturated submodule containing L; it has the same rank as L, and $\text{sat}(L)/L = (M/L)_{\text{tor}}$. If $L \subseteq N \subseteq M$ with N saturated and N/L torsion, then $N = \text{sat}(L)$.

(iii) The following are saturated: kernels of homomorphisms $M \to N$ with N torsion-free; $M \cap W$ for a K-subspace $W \subseteq M \otimes K$; $M[\mathfrak{a}]$ for any action of a ring $\mathbb{T}$ on M and any ideal $\mathfrak{a} \subseteq \mathbb{T}$; and orthogonals for a pairing (Proposition 3.83). Non-examples: $3\mathbb{Z} \subset \mathbb{Z}$; $\mathbb{Z}(3,3) \subset \mathbb{Z}^2$; while $\mathbb{Z}(1,3) \subset \mathbb{Z}^2$ is saturated.

Proof. (i) (a)⇒(c): M/L is finitely generated and torsion-free, hence free (Proposition 3.46(ii)), so $M \twoheadrightarrow M/L$ splits. (c)⇒(a): M/L is isomorphic to a complement, a submodule of the torsion-free M. (a)⇔(b): $x \in M \cap KL$ iff $rx \in L$ for some $r \neq 0$, iff the class of x in M/L is torsion. (a)⇒(d): if $\varpi m \in L$ then $m \in L$ by torsion-freeness of M/L. (d)⇒(a): suppose $rx \in L$ with $r = u\varpi^k$, u a unit; we show $x \in L$ by induction on k. If $k \geq 1$, then $\varpi(\varpi^{k-1}x) \in L \cap \varpi M = \varpi L$, so

$\varpi(\varpi^{k-1}x - l) = 0$ for some $l \in L$, and $\varpi^{k-1}x = l \in L$ because M is torsion-free. (ii) $M/\operatorname{sat}(L)$ embeds in $(M \otimes K)/KL$, a K-vector space, so it is torsion-free. A saturated $N \supseteq L$ satisfies $N = M \cap KN \supseteq M \cap KL$. KL and $K\operatorname{sat}(L)$ coincide, so the ranks agree, and $\operatorname{sat}(L)/L$ consists of the classes killed by some $r \neq 0$. If N/L is torsion, $KN = KL$ and $N = M \cap KN = \operatorname{sat}(L)$. (iii) $M/\ker f \simeq f(M) \subseteq N$; $M/(M \cap W)$ embeds in $(M \otimes K)/W$; $M/M[\mathfrak{a}]$ embeds in $\prod_{a\in\mathfrak{a}} M$ by $x \mapsto (ax)_a$ (the $\mathbb{T}$-action is R-linear). In $\mathbb{Z}/3\mathbb{Z}$ and $\mathbb{Z}^2/\mathbb{Z}(3,3) \simeq \mathbb{Z} \oplus \mathbb{Z}/3$ there is torsion; $\mathbb{Z}(1,3)$ is a direct summand with complement $\mathbb{Z}(0,1)$. □

Theorem 3.50 (stacked bases)**.** *Let M be free of rank n and $L \subseteq M$ a submodule of rank d. There are a basis $e_1, \dots, e_n$ of M and nonzero $d_1 \mid \cdots \mid d_d$ such that $d_1e_1, \dots, d_de_d$ is a basis of L. The ideals (d_i), the* elementary divisors of L in M*, are unique. Hence $M/L \simeq R^{n-d} \oplus \bigoplus_i R/(d_i)$; L is saturated if and only if every d_i is a unit; and if $d = n$ and B is the matrix whose rows are the coordinates of a basis of L in a basis of M, then M/L is torsion, of order $|\det B|$ (the* index $[M : L]$*) when $R = \mathbb{Z}$, and of length $v(\det B)$ when R is a discrete valuation ring.*

Proof. L is free of rank d (Theorem 3.40); let $B \in \mathrm{M}_{d\times n}(R)$ be the matrix of a basis of L in a basis f of M. Its rows are independent, so in Theorem 3.41, $UBV = \operatorname{diag}(d_1, \dots, d_d)$ with all $d_i \neq 0$. The rows of UB form another basis of L, and in the basis $e = V^{-1}f$ of M (that is, $e_i = \sum_j (V^{-1})_{ij} f_j$) their coordinates are the rows of UBV. So d_ie_i is a basis of L. Then $M/L \simeq R^{n-d} \oplus \bigoplus R/(d_i)$, and uniqueness follows from Theorem 3.43 (the number of unit d_i is d minus the number of nonzero torsion summands). The other statements follow. $M/L \simeq R^{n-d} \oplus \bigoplus R/(d_i)$ is torsion-free iff no summand $R/(d_i)$ is nonzero, that is, iff every d_i is a unit. If $d = n$, the free summand disappears and M/L is torsion; from $UBV = \operatorname{diag}(d_1, \dots, d_n)$ we get $\det B = \det(U^{-1}) \det(V^{-1}) \prod d_i$, with $\det U$, $\det V$ units. Over $\mathbb{Z}$ the units are ± 1, so $|\det B| = \prod |d_i| = \#\bigoplus \mathbb{Z}/d_i$; over a discrete valuation ring $v(\det B) = \sum v(d_i) = \operatorname{length} \bigoplus \mathcal{O}/(d_i)$ by Proposition 3.66. □

For example, in $M = \mathbb{Z}^2$ the sublattice L spanned by $(2,0)$ and $(1,3)$ has $B = \begin{pmatrix} 2 & 0 \\ 1 & 3 \end{pmatrix}$, $\det B = 6$, and gcd of the entries 1; so its invariant factors are $1, 6$ (PARI: `matsnf([2,0;1,3])` returns `[6,1]`), and $\mathbb{Z}^2/L \simeq \mathbb{Z}/6$ is cyclic. The theorem says that in a suitable basis e_1, e_2 of $\mathbb{Z}^2$ the lattice is $\mathbb{Z}e_1 \oplus \mathbb{Z}\,6e_2$; one such basis is $e_1 = (1,3)$, $e_2 = (0,1)$, since $(2,0) = 2e_1 - 6e_2$.

Proposition 3.51 (the dual of an inclusion of lattices)**.** *Let $L \subseteq M$ be lattices of the same rank n, so M/L is torsion. Then restriction $M^\vee \to L^\vee$ is injective and $L^\vee/M^\vee \simeq \bigoplus_i R/(d_i)$, with the same invariant factors as M/L. More precisely, there is a canonical isomorphism*

$$L^\vee/M^\vee \xrightarrow{\sim} \operatorname{Hom}_R(M/L, K/R), \qquad \varphi \mapsto (m + L \mapsto \varphi_K(m) + R),$$

where φ_K is the K-linear extension of φ to $M \otimes K = L \otimes K$. For $R = \mathbb{Z}$ or $\mathbb{Z}_\ell$ the right-hand side is the Pontryagin dual $(M/L)^*$ (Theorem 3.76), so $[L^\vee : M^\vee] = [M : L]$. Equivalently: if $A \hookrightarrow B$ is an injection of lattices of the same rank with finite cokernel C, then $B^\vee \hookrightarrow A^\vee$ with cokernel $\simeq C^*$.

Proof. The displayed map is well defined: $\varphi_K(L) = \varphi(L) \subseteq R$, and if $\varphi \in M^\vee$ the image is 0. Its kernel is $\{\varphi : \varphi_K(M) \subseteq R\} = M^\vee$. For surjectivity take stacked bases (Theorem 3.50): $M = \bigoplus Re_i$, $L = \bigoplus Rd_ie_i$. A homomorphism $\psi\colon M/L \to K/R$ is determined by the values $\psi(e_i)$, which are killed by d_i, so $\psi(e_i) = c_i/d_i + R$ with $c_i \in R$; the functional $\varphi = \sum_i c_i e_i^\vee/d_i$ is integral on L and maps to ψ. In these bases $L^\vee$ has basis $e_i^\vee/d_i$ and $M^\vee$ has basis $e_i^\vee$, which gives the

invariant factors. For a finite group, $\mathrm{Hom}(X, \mathbb{Q}/\mathbb{Z})$ and, for an ℓ-primary one, $\mathrm{Hom}(X, \mathbb{Q}_\ell/\mathbb{Z}_\ell)$ are the Pontryagin duals, and $\#X^* = \#X$ (Theorem 3.76). □

The direction of the inclusion is reversed by duality: the smaller lattice has the larger dual. In rank one, $L = 2\mathbb{Z} \subset M = \mathbb{Z}$; the functional $e^\vee$ $(1 \mapsto 1)$ generates $M^\vee$, while $L^\vee$ is generated by the functional $2 \mapsto 1$, which is $\frac{1}{2}e^\vee$ extended to $\mathbb{Q}$. So $L^\vee = \frac{1}{2}\mathbb{Z}e^\vee \supset M^\vee = \mathbb{Z}e^\vee$, of index $2 = [M : L]$, and the isomorphism of the proposition sends $\frac{1}{2}e^\vee$ to the character $1 + 2\mathbb{Z} \mapsto \frac{1}{2} + \mathbb{Z}$ of $\mathbb{Z}/2$.

Remark 3.52. In the language of Chapter 16, $\mathrm{Hom}_R(M/L, K/R) \simeq \mathrm{Ext}^1_R(M/L, R)$, and Proposition 3.51 is the long exact Ext sequence of $0 \to L \to M \to M/L \to 0$. We do not need this.

Proposition 3.53 (the congruence module of a decomposition)**.** *Let M be a lattice, $M \otimes K = V_1 \oplus V_2$ a decomposition into K-subspaces with projections p_1, p_2, and $L_i = M \cap V_i$ (saturated).*

(i) $L_1 \oplus L_2 \subseteq M$ has torsion quotient, and $x \mapsto p_i(x)$ induces isomorphisms $M/(L_1 \oplus L_2) \simeq p_1(M)/L_1 \simeq p_2(M)/L_2$.

(ii) Suppose $V_1 = Kf$ with $f \in M$ and $L_1 = Rf$ (that is, f is primitive). Then $M/(L_1 \oplus L_2)$ embeds in $Kf/Rf \simeq K/R$, so it is cyclic, $\simeq R/(r)$, generated by the class of any $h \in M$ with $p_1(h) = f/r$; then $rh = f + g_0$ with $g_0 \in L_2$, so $f \equiv -g_0 \pmod{rM}$. For $0 \neq r' \in R$ there is $g \in L_2$ with $f \equiv g \pmod{r'M}$ if and only if $r' \mid r$. So (r) is the congruence modulus *of f against L_2: the largest modulus of a congruence between f and an element of L_2.*

(iii) Example: $M = \mathbb{Z}^2$, $f = (1, a)$, $g = (1, b)$ with $a \neq b$, $V_1 = \mathbb{Q}f$, $V_2 = \mathbb{Q}g$. Then $L_1 = \mathbb{Z}f$, $L_2 = \mathbb{Z}g$, $M/(\mathbb{Z}f \oplus \mathbb{Z}g) \simeq \mathbb{Z}/(a - b)$, and $f \equiv g \pmod{(a - b)}$ coordinatewise.

Proof. (i) Every $v \in V_1$ has a nonzero multiple in M (which spans $M \otimes K$), hence in L_1; so L_1 spans V_1, likewise L_2, and the quotient has rank 0. The map $M \to p_1(M)/L_1$ is onto; x lies in its kernel iff $p_1(x) \in L_1 \subseteq M$, and then $p_2(x) = x - p_1(x) \in M \cap V_2 = L_2$; so the kernel is $L_1 \oplus L_2$. Symmetrically for p_2. (ii) $p_1(M)$ is a finitely generated submodule of Kf containing Rf, hence free of rank one, $p_1(M) = R(f/r)$ for some $r \neq 0$ (a generator u satisfies $f = su$, so $u = f/s$). By (i) the quotient is $R(f/r)/Rf \simeq R/(r)$, generated by any h with $p_1(h) = f/r$. Then $rh - f = rp_2(h) \in M \cap V_2 = L_2$. If $f - g = r'm$ with $g \in L_2$ and $m \in M$, then $p_1(m) = f/r' \in R(f/r)$, so $r = sr'$; conversely $f \equiv -g_0 \pmod{rM}$ implies the congruence modulo every divisor r' of r. (iii) f and g are primitive, so $L_1 = \mathbb{Z}f$ and $L_2 = \mathbb{Z}g$, and the index of $\mathbb{Z}f \oplus \mathbb{Z}g$ is $|\det \begin{pmatrix} 1 & a \\ 1 & b \end{pmatrix}| = |b - a|$ (Theorem 3.50); the quotient is cyclic by (ii), and $f - g = (0, a - b)$. □

Here is (ii) in the case $a = 0$, $b = 4$ of (iii), so $f = (1, 0)$, $g = (1, 4)$ and $r = 4$. To project $h = (0, -1)$ onto $\mathbb{Q}f$ along $\mathbb{Q}g$, solve $(0, -1) = \alpha(1, 0) + \beta(1, 4)$: $\beta = -\frac{1}{4}$, $\alpha = \frac{1}{4}$, so $p_1(h) = f/4$, and h generates the quotient $\mathbb{Z}^2/(\mathbb{Z}f \oplus \mathbb{Z}g) \simeq \mathbb{Z}/4$. Then $4h = (0, -4) = f + g_0$ with $g_0 = (-1, -4) = -g \in L_2$, and $f \equiv -g_0 = g \pmod{4\mathbb{Z}^2}$, the congruence of the two vectors modulo 4. No congruence modulo 8 exists: $f - mg = (1 - m, -4m)$ lies in $8\mathbb{Z}^2$ only if $m \equiv 1 \pmod 8$ and $4m \equiv 0 \pmod 8$, which is impossible. This is the pattern of the second paragraph of the proof of Lemma lem:crit, with f a newform and g ranging over the other forms.

In the paper 3.54. The second paragraph of the proof of Lemma lem:crit is Propositions 3.51 and 3.53 with $M = S_2(\Gamma_0(N);\mathbb{Z})$, $V_1 = \mathbb{Q}f$, $V_2 = f^\perp$, $L_1 = \mathbb{Z}f$ (as $a_1(f) = 1$, f is primitive) and $L_2 = L = f^\perp \cap S_2(\Gamma_0(N);\mathbb{Z})$. "Dualising the inclusion $\mathbb{T} \subset \mathbb{T}/I \times \mathbb{T}/J$, whose cokernel is $\mathbb{T}/(I+J)$, shows that $\mathbb{Z}f \oplus L$ has index r'" is Proposition 3.91(iii), which rests on Proposition 3.51. That the quotient $S_2(\Gamma_0(N);\mathbb{Z})/(\mathbb{Z}f \oplus L)$ "embeds in $\mathbb{Q}f/\mathbb{Z}f$ by projection onto $\mathbb{Q}f$ along $f^\perp$, so it is cyclic, generated by the class of a form h with projection f/r'; then $r'h = f + g_0$ with $g_0 \in L$" is Proposition 3.53(ii), whose last clause is the paper's "$r' \le r$" and "$r \mid r'$" in one statement: the congruence number is the congruence modulus. Lemma lem:ddt417 uses the same structure, with $L \otimes K = L[\wp]_K \oplus L[I]_K$ and $Q = L/(L[\wp] \oplus L[I])$.

3.6 Discrete valuation rings, $\mathbb{Z}_\ell$, $\mathbb{Q}_\ell$ and $\mathbb{Q}_\ell/\mathbb{Z}_\ell$

The coefficient rings of the paper are discrete valuation rings: $\mathbb{Z}_\ell$ everywhere, $\mathcal{O}$ in Lemma lem:ddt417 and Section 4.1, $\mathbb{Z}_3[\zeta_3]$ in Lemma lem:IV. Over such a ring finitely generated modules are classified by a rank and a list of exponents, which is what makes lengths and Fitting ideals computable (Section 3.7). The module $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ carries the discrete coefficients $W = \mathrm{ad}^0 T \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$ of the paper's Selmer groups, and its injectivity makes Pontryagin duality exact (Section 3.8). Here $\mathbb{Z}_\ell$ is built algebraically; the analytic theory is Chapter 7 (Warning 3.62).

Theorem 3.55 (discrete valuation rings)**.** *Let $\mathcal{O}$ be a Noetherian local domain that is not a field, with maximal ideal $\mathfrak{m}$ and fraction field K. The following are equivalent:*

(a) $\mathfrak{m}$ is principal;

(b) $\mathcal{O}$ is a principal ideal domain;

(c) every nonzero ideal is a power of $\mathfrak{m}$;

(d) there is a surjective homomorphism $v\colon K^\times \to \mathbb{Z}$ with $v(x+y) \ge \min(v(x), v(y))$ and $\mathcal{O} = \{x \in K^\times : v(x) \ge 0\} \cup \{0\}$;

(e) $\mathcal{O}$ is integrally closed in K (and of dimension one).

Such a ring is a discrete valuation ring*. A generator ϖ of $\mathfrak{m}$ is a* uniformiser*; every $x \in K^\times$ is uniquely $x = u\varpi^{v(x)}$ with $u \in \mathcal{O}^\times$; $\mathcal{O}^\times = \{v = 0\}$; and the nonzero ideals are the $\varpi^k\mathcal{O}$, $k \ge 0$.*

Proof. (a)⇒(c),(d),(b). Let $\mathfrak{m} = \varpi\mathcal{O}$. First, $\bigcap_k \mathfrak{m}^k = 0$: if $x = \varpi^k y_k$ for every k, then $\varpi^k y_k = \varpi^{k+1} y_{k+1}$ gives $y_k = \varpi y_{k+1}$ ($\mathcal{O}$ is a domain), so $(y_0) \subseteq (y_1) \subseteq \cdots$; this chain stabilises, $y_{k+1} = u y_k$ for some k and $u \in \mathcal{O}$, so $(1 - \varpi u)y_k = 0$, and $1 - \varpi u$ is a unit (Proposition 3.34); hence $y_k = 0$ and $x = 0$. So every $x \ne 0$ lies in $\mathfrak{m}^k$ but not $\mathfrak{m}^{k+1}$ for a unique k; then $x = \varpi^k u$ with $u \notin \mathfrak{m}$, a unit. The exponent is unique: $\varpi^k u = \varpi^j u'$ with $k < j$ would give $u = \varpi^{j-k}u' \in \mathfrak{m}$. Put $v(x) = k$. On $\mathcal{O} \setminus \{0\}$ it is additive: $x = \varpi^a u$, $y = \varpi^b u'$ give $xy = \varpi^{a+b}uu'$ with uu' a unit, so $v(xy) = v(x) + v(y)$. Extend by $v(x/y) = v(x) - v(y)$; this is well defined, since $x/y = x'/y'$ means $xy' = x'y$, whence $v(x) + v(y') = v(x') + v(y)$, and it is a homomorphism $K^\times \to \mathbb{Z}$, onto because $v(\varpi) = 1$. Finally $v(x+y) \ge \min(v(x), v(y))$ because $\varpi^{\min}$ divides both (clear denominators first for elements of K). A nonzero ideal $\mathfrak{a}$ contains an element of least valuation k, and then $\mathfrak{a} = \varpi^k\mathcal{O}$. This proves (c), (d) and (b). (b)⇒(a): trivial. (c)⇒(a): $\mathfrak{m} \ne \mathfrak{m}^2$, since otherwise $\mathfrak{m} = 0$ by Nakayama ($\mathfrak{m}$ is finitely generated); pick $\varpi \in \mathfrak{m} \setminus \mathfrak{m}^2$; then $\varpi\mathcal{O} = \mathfrak{m}^k$ for some k, and $k = 1$: $k = 0$ would make ϖ a unit, and $k \ge 2$ would put ϖ in $\mathfrak{m}^2$. (d)⇒(a): pick

ϖ with $v(\varpi) = 1$. If $x \in \mathfrak{m}$ then $v(x) \geq 1$ (if $v(x) = 0$ then $v(x^{-1}) = 0$ and $x^{-1} \in \mathcal{O}$), so $x/\varpi \in \mathcal{O}$. (e): we do not prove the equivalence with (e); see [7, Proposition 9.2] (number not verified against the printed edition) or [174, Chapter I, Section 2]. It is used only in Chapter 6. The last statements were proved along the way. □

A discrete valuation ring $\mathcal{O}$ is *complete* if the map $\mathcal{O} \to \varprojlim_n \mathcal{O}/\varpi^n\mathcal{O}$ is an isomorphism. Then every finitely generated $\mathcal{O}$-module M, in particular every free one of finite rank, is complete: $M \to \varprojlim_n M/\varpi^n M$ is an isomorphism, by the proof of Theorem 3.58(vi), which uses only completeness of the ring. $\mathbb{Z}_\ell$ is complete (Theorem 3.58(vi)); $\mathbb{Z}_{(\ell)}$ is not, since $\varprojlim \mathbb{Z}_{(\ell)}/\ell^n = \varprojlim \mathbb{Z}/\ell^n = \mathbb{Z}_\ell$ is uncountable.

Example 3.56. Discrete valuation rings: $\mathbb{Z}_{(p)}$ (Chapter 2); $F[[x]]$ for a field F (every nonzero series is $x^k u$ with u a unit, since a series with nonzero constant term is invertible, so the ideals are the (x^k)); $\mathbb{Z}_\ell$ (Theorem 3.58); and, with proofs in Chapters 6 and 7, $\mathbb{Z}_3[\zeta_3]$, $\mathbb{Z}_\ell[\zeta_3]$ for $\ell \equiv 2 \pmod 3$, and the completions $\mathcal{O}_\lambda$ of rings of integers. Not discrete valuation rings: $\mathbb{Z}$ (not local); $\mathbb{Z}/p^2$ and $\mathcal{O}[x]/(x^2)$ (not domains); $\mathbb{Z}_\ell \times \mathbb{Z}_\ell$ (not local); $\mathbb{Z}_\ell[x]$ (not local: (ℓ, x) and $(x-1, \ell)$ are distinct maximal ideals); $\mathbb{Z}_{(11)}[x]/(x^2+x-1)$ (a domain with two maximal ideals, Theorem 3.95(v)).

Proposition 3.57 (modules over a discrete valuation ring)**.** *Let M be a finitely generated $\mathcal{O}$-module.*

(i) $M \simeq \mathcal{O}^r \oplus \bigoplus_{i=1}^s \mathcal{O}/\varpi^{a_i}$ *with $a_i \geq 1$; r and the multiset $\{a_i\}$ are unique.*

(ii) If M is torsion-free, it is free.

(iii) $\dim_k M/\varpi M = r + s$ *is the minimal number of generators, and* $\dim_k M[\varpi] = s$.

(iv) If $r = 0$ then $M[\varpi^k] \simeq \bigoplus_i \mathcal{O}/\varpi^{\min(k,a_i)}$; in general $M/\varpi^k M \simeq (\mathcal{O}/\varpi^k)^r \oplus \bigoplus_i \mathcal{O}/\varpi^{\min(k,a_i)}$.

(v) M is cyclic if and only if $r + s \leq 1$; a torsion M with $\dim_k M[\varpi] \leq 1$ is cyclic.

(vi) A submodule L of a lattice M is saturated if and only if $L \cap \varpi M = \varpi L$.

Proof. (i) is Theorem 3.43, as ϖ is the only prime up to units; (ii) is Proposition 3.46(ii). For (iii) and (iv) compute summand by summand. For the summand $\mathcal{O}$: $\mathcal{O}/\varpi\mathcal{O} = k$ and $\mathcal{O}[\varpi] = 0$. For $\mathcal{O}/\varpi^a$: the quotient by ϖ is k, the ϖ-torsion is $\varpi^{a-1}\mathcal{O}/\varpi^a \simeq k$, the ϖ^k-torsion is $\varpi^{\max(a-k,0)}\mathcal{O}/\varpi^a \simeq \mathcal{O}/\varpi^{\min(k,a)}$, and the quotient by ϖ^k is $\mathcal{O}/\varpi^{\min(k,a)}$. The minimal number of generators is Theorem 3.35(iii). (v) By (iii) the minimal number of generators is $r + s$, so M is cyclic iff $r + s \leq 1$; if M is torsion then $r = 0$, and $s = \dim_k M[\varpi] \leq 1$. (vi) is Proposition 3.49(i)(d). □

For instance $M = \mathcal{O}/\varpi^2 \oplus \mathcal{O}/\varpi$ has $r = 0$, $s = 2$: it needs two generators, $M[\varpi] = \varpi\mathcal{O}/\varpi^2 \oplus \mathcal{O}/\varpi \simeq k^2$, and $M[\varpi^2] = M$, $M/\varpi M \simeq k^2$, in accordance with (iv). In general the two numbers $\dim_k M/\varpi M$ and $\dim_k M[\varpi]$ differ exactly by the rank r, so together they determine r and the number s of torsion summands, though not the exponents a_i.

Theorem 3.58 (the ring $\mathbb{Z}_\ell$)**.** *Let $\mathbb{Z}_\ell = \varprojlim_n \mathbb{Z}/\ell^n$, the ring of compatible sequences $x = (x_n)_{n\geq 1}$, $x_n \in \mathbb{Z}/\ell^n$, $x_{n+1} \equiv x_n \pmod{\ell^n}$, with componentwise operations (as a profinite group it is constructed in Chapter 1).*

(i) x is a unit if and only if $x_1 \neq 0$ in $\mathbb{F}_\ell$.

(ii) Every nonzero x is uniquely $\ell^k u$ with $k \geq 0$ and $u \in \mathbb{Z}_\ell^\times$. Hence $\mathbb{Z}_\ell$ is a discrete valuation ring with uniformiser ℓ, residue field $\mathbb{F}_\ell$ (via $x \mapsto x_1$) and ideals $\ell^k\mathbb{Z}_\ell$, and its valuation extends v_ℓ on $\mathbb{Z}$.

(iii) $\mathbb{Z} \to \mathbb{Z}_\ell$, $n \mapsto (n \bmod \ell^k)_k$, is injective; $\mathbb{Z}_{(\ell)} \subseteq \mathbb{Z}_\ell$; and $x \mapsto x_n$ induces $\mathbb{Z}_\ell/\ell^n\mathbb{Z}_\ell \simeq \mathbb{Z}/\ell^n$. An integer prime to ℓ is a unit of $\mathbb{Z}_\ell$, so a $\mathbb{Z}_\ell$-module killed by an integer prime to ℓ is 0.

(iv) $\mathbb{Q}_\ell := \operatorname{Frac}(\mathbb{Z}_\ell) = \mathbb{Z}_\ell[1/\ell]$, and $\mathbb{Q} \cap \mathbb{Z}_\ell = \mathbb{Z}_{(\ell)}$ inside $\mathbb{Q}_\ell$.

(v) $\mathbb{Z}_\ell$ is flat over $\mathbb{Z}$. For a finitely generated abelian group $A \simeq \mathbb{Z}^r \oplus A_{\mathrm{tor}}$, $A \otimes_{\mathbb{Z}} \mathbb{Z}_\ell \simeq \mathbb{Z}_\ell^r \oplus A_{\mathrm{tor}}[\ell^\infty]$; for finite A, $\#(A \otimes \mathbb{Z}_\ell) = \ell^{v_\ell(\#A)}$, the ℓ-part of $\#A$.

(vi) Every finitely generated $\mathbb{Z}_\ell$-module M is complete: $M \to \varprojlim_n M/\ell^n M$ is an isomorphism.

(vii) More generally, for a Noetherian ring R and an ideal I, the I-adic completion $\hat{R} = \varprojlim R/I^n$ is Noetherian and flat over R, and $\hat{M} = \varprojlim M/I^n M \simeq M \otimes_R \hat{R}$ for finitely generated M.

Proof. (i) If $x_1 \neq 0$, then $\ell \nmid x_n$ for all n, so each x_n is a unit of $\mathbb{Z}/\ell^n$, and the inverses are compatible (inverses are unique); conversely x_1 is the image of x in the field $\mathbb{F}_\ell$. (ii) Let $x \neq 0$ and let k be the largest index with $x_k = 0$ (with $x_0 = 0$ by convention); it exists because $x_n = 0$ forces $x_j = 0$ for $j \leq n$. For $n \geq 1$, $x_{n+k} \equiv x_k = 0 \pmod{\ell^k}$, so $x_{n+k} = \ell^k y_n$ with $y_n \in \mathbb{Z}/\ell^n$ well defined; the y_n are compatible, $y_1 \neq 0$ because $x_{k+1} \neq 0$, so $u = (y_n)$ is a unit with $x = \ell^k u$. Then $k = v(x)$ is determined by x. Since $\ell^k \neq 0$ (its component at $k+1$ is nonzero), the product $\ell^{a+b}uu'$ of two nonzero elements is nonzero: $\mathbb{Z}_\ell$ is a domain. A nonzero ideal is $\ell^k\mathbb{Z}_\ell$ for its least valuation k, so $\mathbb{Z}_\ell$ is a principal ideal domain, local with maximal ideal $\ell\mathbb{Z}_\ell$ (the non-units, by (i)): a discrete valuation ring by Theorem 3.55. The kernel of $x \mapsto x_1$ is $\{v \geq 1\} = \ell\mathbb{Z}_\ell$. (iii) $n \neq 0$ has nonzero image in $\mathbb{Z}/\ell^k$ for $\ell^k > |n|$. By (ii), $x_n = 0$ iff $v(x) \geq n$, so the kernel of $x \mapsto x_n$ is $\ell^n\mathbb{Z}_\ell$; it is onto because $\mathbb{Z}$ maps onto $\mathbb{Z}/\ell^n$. Integers prime to ℓ are units by (i), which gives $\mathbb{Z}_{(\ell)} \subseteq \mathbb{Z}_\ell$. (iv) $x/y = x\ell^{-v(y)}u^{-1}$ for $y = \ell^{v(y)}u$. By (iii), $\mathbb{Q} \subseteq \mathbb{Q}_\ell$ and $\mathbb{Z}_{(\ell)} \subseteq \mathbb{Z}_\ell$. Conversely, if a/b is in lowest terms with $\ell \mid b$, then $\ell \nmid a$ and $v(a/b) = -v_\ell(b) < 0$ by (ii), so $a/b \notin \mathbb{Z}_\ell$. (v) $\mathbb{Z}_\ell$ is torsion-free over $\mathbb{Z}$, hence flat (Proposition 3.29(ii)). $\mathbb{Z}/n \otimes \mathbb{Z}_\ell = \mathbb{Z}_\ell/n\mathbb{Z}_\ell = \mathbb{Z}_\ell/\ell^{v_\ell(n)}\mathbb{Z}_\ell \simeq \mathbb{Z}/\ell^{v_\ell(n)}$ by (ii), (iii); sum over the cyclic summands of A. (vi) For $M = \mathbb{Z}_\ell$ the map $\mathbb{Z}_\ell \to \varprojlim \mathbb{Z}_\ell/\ell^n\mathbb{Z}_\ell = \varprojlim \mathbb{Z}/\ell^n = \mathbb{Z}_\ell$ is the identity; for $M = \mathbb{Z}/\ell^a$ the system is eventually constant; and both sides commute with finite direct sums. Conclude by Proposition 3.57(i). (vii) We do not prove this; see [7, Chapter 10] (the Artin-Rees lemma) or [62, Chapter 7]. □

Lemma 3.59 (Baer's criterion over a principal ideal domain)**.** *Let R be a principal ideal domain and D a* divisible *R-module ($dD = D$ for every $d \neq 0$). Then D is* injective*: for every submodule $N \subseteq M$, every homomorphism $N \to D$ extends to M. Consequently $\operatorname{Hom}_R(-, D)$ is exact.*

Proof. Let $f\colon N \to D$. By Zorn's lemma there is a maximal extension $f_0\colon N_0 \to D$ ($N \subseteq N_0 \subseteq M$), the union of a chain of extensions being an extension. Suppose $m \in M \setminus N_0$. The ideal $\{r : rm \in N_0\}$ is dR. If $d = 0$, extend by $f(n + rm) = f_0(n)$. If $d \neq 0$, choose $y \in D$ with $dy = f_0(dm)$ and put $f(n + rm) = f_0(n) + ry$. This is well defined: if $n + rm = 0$ then $rm \in N_0$, so $r = sd$, and $f_0(n) + ry = f_0(n) + sf_0(dm) = f_0(n + rm) = 0$. This contradicts maximality, so $N_0 = M$. Exactness of $\operatorname{Hom}(-, D)$: by Proposition 3.25(ii) only surjectivity of $\operatorname{Hom}(M, D) \to \operatorname{Hom}(N, D)$ for $N \subseteq M$ remains, and that is injectivity of D. □

The choice of y is the only place where divisibility is used, and it cannot be avoided: $\mathbb{Z}$ is not divisible and not injective, since the map $2\mathbb{Z} \to \mathbb{Z}$, $2 \mapsto 1$, has no extension to $\mathbb{Z}$ (it would send 1

to an integer y with $2y = 1$). Over $\mathbb{Z}$ the divisible groups $\mathbb{Q}$, $\mathbb{Q}/\mathbb{Z}$ and $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ are injective, and these are the coefficient groups of duality.

Proposition 3.60 (the module $\mathbb{Q}_\ell/\mathbb{Z}_\ell$)**.** *(i) $\mathbb{Q}_\ell/\mathbb{Z}_\ell \simeq \mathbb{Z}[1/\ell]/\mathbb{Z} \simeq (\mathbb{Q}/\mathbb{Z})[\ell^\infty] \simeq \varinjlim_k \mathbb{Z}/\ell^k$, the transition maps being multiplication by ℓ. As an abstract group it is isomorphic to μ_{ℓ^∞} (no Galois action is involved here).*

(ii) It is divisible and ℓ-primary torsion; $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)[\ell^k] = \ell^{-k}\mathbb{Z}_\ell/\mathbb{Z}_\ell \simeq \mathbb{Z}/\ell^k$; its proper $\mathbb{Z}_\ell$-submodules are exactly these.

(iii) The ring $\mathrm{End}_{\mathbb{Z}_\ell}(\mathbb{Q}_\ell/\mathbb{Z}_\ell)$ is $\mathbb{Z}_\ell$, acting by multiplication; moreover $\mathrm{Hom}_{\mathbb{Z}_\ell}(\mathbb{Z}/\ell^k, \mathbb{Q}_\ell/\mathbb{Z}_\ell) \simeq \mathbb{Z}/\ell^k$, and $\mathrm{Hom}_{\mathbb{Z}_\ell}(\mathbb{Z}_\ell, \mathbb{Q}_\ell/\mathbb{Z}_\ell) = \mathbb{Q}_\ell/\mathbb{Z}_\ell$.

(iv) $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ is an injective $\mathbb{Z}_\ell$-module and $\mathbb{Q}/\mathbb{Z}$ an injective $\mathbb{Z}$-module; so $\mathrm{Hom}(-, \mathbb{Q}_\ell/\mathbb{Z}_\ell)$ and $\mathrm{Hom}(-, \mathbb{Q}/\mathbb{Z})$ are exact.

Proof. (i) Every element of $\mathbb{Q}_\ell$ is $x = \ell^{-k}u$ with $u \in \mathbb{Z}_\ell$; choosing $a \in \mathbb{Z}$ with $u \equiv a \pmod{\ell^k}$ gives $x \equiv a/\ell^k$ modulo $\mathbb{Z}_\ell$. So $\mathbb{Z}[1/\ell] \to \mathbb{Q}_\ell/\mathbb{Z}_\ell$ is onto, with kernel $\mathbb{Z}[1/\ell] \cap \mathbb{Z}_\ell = \mathbb{Z}$. A class $a/b + \mathbb{Z}$ in reduced form is killed by a power of ℓ iff b is a power of ℓ, which identifies $\mathbb{Z}[1/\ell]/\mathbb{Z}$ with $(\mathbb{Q}/\mathbb{Z})[\ell^\infty]$; and $\mathbb{Z}/\ell^k \simeq \ell^{-k}\mathbb{Z}/\mathbb{Z}$. The map $\mathbb{Z}[1/\ell]/\mathbb{Z} \to \mu_{\ell^\infty}$, $x \mapsto e^{2\pi i x}$, is an isomorphism. (ii) Divisibility: $x = \ell^{-k}u$ is $\ell^j u'$ times $\ell^{-k-j}u'^{-1}u$ for any j and unit u'. The ℓ^k-torsion is $\ell^{-k}\mathbb{Z}_\ell/\mathbb{Z}_\ell$, cyclic of order ℓ^k. A submodule containing elements of every order contains every $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)[\ell^k]$, since an element of exact order ℓ^k generates this cyclic group; otherwise it lies in some $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)[\ell^k]$ and is one of its subgroups $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)[\ell^j]$. (iii) An endomorphism ϕ preserves each $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)[\ell^k] \simeq \mathbb{Z}/\ell^k$, where it is multiplication by some $a_k \in \mathbb{Z}/\ell^k$; the a_k are compatible, so ϕ is multiplication by $a = (a_k) \in \mathbb{Z}_\ell$, and $a \neq 0$ acts nontrivially. The other two are Proposition 3.25(i). (iv) Both are divisible (for $\mathbb{Q}/\mathbb{Z}$ over $\mathbb{Z}$, x/n divides x), so Lemma 3.59 applies. □

Proposition 3.61 (the topology of finitely generated $\mathbb{Z}_\ell$-modules)**.** *Give every finitely generated $\mathbb{Z}_\ell$-module M the ℓ-adic topology, in which the $\ell^n M$ form a basis of neighbourhoods of 0.*

(i) M is compact, Hausdorff and complete.

(ii) Every $\mathbb{Z}_\ell$-linear map between finitely generated modules is continuous; every submodule of M is finitely generated and closed, and every linear map has closed image.

(iii) $\mathrm{GL}_n(\mathbb{Z}_\ell) = \mathrm{Aut}_{\mathbb{Z}_\ell}(\mathbb{Z}_\ell^n) = \varprojlim_k \mathrm{GL}_n(\mathbb{Z}/\ell^k)$ is profinite (Chapter 1).

(iv) (Topological Nakayama.) A compact Hausdorff $\mathbb{Z}_\ell$-module A on which $\mathbb{Z}_\ell$ acts continuously and with $A/\ell A$ finite is finitely generated.

Proof. (i) $M \simeq \mathbb{Z}_\ell^r \oplus F$ with F finite, and $\ell^n M$ corresponds to $(\ell^n\mathbb{Z}_\ell)^r \oplus \ell^n F$, so the ℓ-adic topology is the product topology. $\mathbb{Z}_\ell = \varprojlim \mathbb{Z}/\ell^n$ is a closed subset of the compact product $\prod \mathbb{Z}/\ell^n$ of finite discrete sets, and its subspace topology has the basis $\ell^n\mathbb{Z}_\ell$ (the kernels of the projections). Completeness is Theorem 3.58(vi). (ii) $f(\ell^n M) \subseteq \ell^n N$, so f is continuous. A submodule N is finitely generated (Proposition 3.31), hence the image of a continuous map $\mathbb{Z}_\ell^s \to M$, hence compact, hence closed. The same applies to $f(M)$. (iii) A matrix over $\mathbb{Z}_\ell$ is invertible iff it is invertible modulo ℓ (Theorem 3.35(iv)), and $\mathbb{Z}_\ell^{n\times n} = \varprojlim (\mathbb{Z}/\ell^k)^{n\times n}$. □

Sketch of proof of (iv). By Pontryagin duality for compact and discrete modules, which is Theorem 3.77(v), the dual A^* is a discrete ℓ-primary module with $A^*[\ell] = (A/\ell A)^*$ finite, hence cofinitely generated, so $A = A^{**}$ is finitely generated by Theorem 3.77(ii). The duality theory for compact modules is in [143, Chapter I, Section 1, and Chapter V, Section 2] and [167, Appendix B] (section numbers not verified against the printed editions). □

Warning 3.62. Theorem 3.58 constructs $\mathbb{Z}_\ell$ as a ring and proves only what is needed for modules. The absolute value, the description of $\mathbb{Q}_p$ as the completion of $\mathbb{Q}$, Hensel's lemma and the structure of $\mathbb{Z}_p^\times$ and $\mathbb{Q}_p^\times$ are proved in Chapter 7. Idempotent lifting (Theorem 3.95) is proved below by a Newton iteration that uses only completeness, not Hensel's lemma.

In the paper 3.63. After Lemma lem:dfg21 the paper says: "At ∞, $H^1(\mathbb{R}, T^D)$ is killed by 2, so $H^1_f(\mathbb{R}, T^D) = 0$ for ℓ odd". The group $H^1(\mathbb{R}, T^D)$ is a $\mathbb{Z}_\ell$-module (Chapter 16) killed by the integer 2, which is a unit of $\mathbb{Z}_\ell$ for ℓ odd (Theorem 3.58(iii)); so it is 0, and so is its submodule $H^1_f(\mathbb{R}, T^D)$. In Lemma lem:fpr, "a nonzero rational number which is an ℓ-adic integer" means an element of $\mathbb{Q} \cap \mathbb{Z}_\ell = \mathbb{Z}_{(\ell)}$ (Theorem 3.58(iv)).

3.7 Length, annihilators and Fitting ideals

The paper measures its finite modules in two ways. Selmer groups and H^0 are measured by their length over $\mathbb{Z}_\ell$ (Theorem thm:main, Theorem thm:dfg37, Remark rem:ns, Lemma lem:h0). Tamagawa factors are *Fitting ideals*: Section 1.2 defines $\mathrm{Tam}_p(M) = \mathrm{Fitt}_{\mathbb{Z}_\ell}\big((H^1(I_p, M)_{\mathrm{tor}})^{G_{\mathbb{Q}_p}}\big)$, and Lemma lem:fpr reads $\mathrm{Fitt}_{\mathbb{Z}_\ell} H^1_f(\mathbb{Q}_p, T^D) = L_p(A_f, 1)^{-1}\,\mathrm{Tam}_p(T^D)$. The main result of this section, Theorem 3.72, says that over a discrete valuation ring the two measurements agree: $\mathrm{Fitt} = \varpi^{\mathrm{length}}$. It is the reason why the paper can add valuations of Tamagawa factors to lengths of Selmer groups. The Jordan-Holder theorem is proved here for modules over any ring; Chapter 4 uses it for composition factors of representations.

Definition 3.64 (composition series and length)**.** In this definition and in Theorem 3.65, R is any ring with 1 (not necessarily commutative) and modules are left modules. A module is *simple* if it is nonzero and has no submodules other than 0 and itself. A *composition series* of M is a chain $0 = M_0 \subsetneq M_1 \subsetneq \cdots \subsetneq M_n = M$ with every M_i/M_{i-1} simple; n is its *length* and the M_i/M_{i-1} are its *factors*. The *length* $\mathrm{length}_R(M)$ is the length of any composition series (well defined by Theorem 3.65), and $\mathrm{length}_R(M) = \infty$ if M has none.

Theorem 3.65 (Jordan-Holder; length)**.** *Let R be any ring.*

(i) If M has a composition series, then every chain of submodules of M is finite and can be refined to a composition series, and any two composition series of M have the same length and the same factors up to order and isomorphism (Jordan-Holder). Submodules and quotients of M have composition series.

(ii) A module has finite length if and only if it is Noetherian and Artinian (descending chains stabilise).

(iii) (Additivity.) For an exact sequence $0 \to M' \to M \to M'' \to 0$, $\mathrm{length}(M) = \mathrm{length}(M') + \mathrm{length}(M'')$ (in $\mathbb{Z}_{\geq 0} \cup \{\infty\}$). For an exact sequence $0 \to M_1 \to \cdots \to M_k \to 0$ of modules of finite length, $\sum_i (-1)^i \mathrm{length}(M_i) = 0$.

Now let R be commutative.

(iv) Let R be local, with maximal ideal $\mathfrak{m}$ and residue field k. Every simple module is isomorphic to k. If $\mathfrak{m}^N M = 0$, then $\operatorname{length}_R(M) = \sum_{i<N} \dim_k \mathfrak{m}^i M/\mathfrak{m}^{i+1}M$. If R is Noetherian local, a finitely generated module has finite length if and only if it is killed by a power of $\mathfrak{m}$.

(v) If $R \to R'$ is a local homomorphism of local rings ($\mathfrak{m}_R$ maps into $\mathfrak{m}_{R'}$), R' is finitely generated as an R-module and $f = [k' : k]$ is the degree of the residue field extension, then $\operatorname{length}_R(M) = f \cdot \operatorname{length}_{R'}(M)$ for every R'-module M of finite length.

Proof. (i) For a module X with a composition series let $\lambda(X)$ be the least length of a composition series of X. *Step 1: if $N \subsetneq M$ then N has a composition series and $\lambda(N) < \lambda(M)$.* Let $(M_i)_{i\le n}$ be a composition series with $n = \lambda(M)$ and put $N_i = N \cap M_i$. Then $N_i/N_{i-1} = N_i/(N_i \cap M_{i-1}) \simeq (N_i + M_{i-1})/M_{i-1} \subseteq M_i/M_{i-1}$ (Theorem 3.8(ii), which holds verbatim over any ring), so it is 0 or simple. Deleting repetitions gives a composition series of N of length at most n. If the length were n, every N_i/N_{i-1} would be nonzero, hence equal to M_i/M_{i-1} inside it; by induction on i, $N_{i-1} = M_{i-1}$ and $N_i + M_{i-1} = M_i$ give $N_i = M_i$, so $N = M$, a contradiction. *Step 2: lengths.* A strictly decreasing chain $M = K_0 \supsetneq K_1 \supsetneq \cdots \supsetneq K_j$ gives $\lambda(M) > \lambda(K_1) > \cdots > \lambda(K_j) \ge 0$ by Step 1, so $j \le \lambda(M)$. Hence every chain is finite of length at most $\lambda(M)$, every composition series has length exactly $\lambda(M)$ (it is at most $\lambda(M)$ and at least $\lambda(M)$ by minimality), and a chain can be refined by inserting terms until all quotients are simple, which must stop. *Step 3: factors.* Induction on $n = \lambda(M)$, the case $n \le 1$ being clear. Let (M_i) and (M'_i) be composition series, both of length n by Step 2. If $M_{n-1} = M'_{n-1}$, apply the induction hypothesis to M_{n-1}, of length $n-1$. Otherwise $M_{n-1} + M'_{n-1} = M$ (it strictly contains M_{n-1}, and M/M_{n-1} is simple). Put $K = M_{n-1} \cap M'_{n-1}$. By Theorem 3.8(ii), $M/M_{n-1} \simeq M'_{n-1}/K$ and $M/M'_{n-1} \simeq M_{n-1}/K$, both simple. K has a composition series (K_j) (Step 1), of length $n-2$, because (K_j) followed by M_{n-1} is a composition series of M_{n-1}, of length $n-1$. By induction, the factors of $(M_i)_{i\le n-1}$ are those of (K_j) together with $M_{n-1}/K \simeq M/M'_{n-1}$; so the factors of (M_i) are those of (K_j) together with M/M'_{n-1} and M/M_{n-1}. The same computation for (M'_i) gives the factors of (K_j) together with $M'_{n-1}/K \simeq M/M_{n-1}$ and M/M'_{n-1}: the same list. Quotients: the image in M/N of a composition series of M has successive quotients that are quotients of simple modules, so 0 or simple. (ii) We do not prove this; see [7, Proposition 6.8] (number not verified). We use only the direction "finite length implies Noetherian", which is Step 2. (iii) If M has finite length so do M' and M'' by (i); conversely, the preimage in M of a composition series of M'', placed after a composition series of M', is a composition series of M. Its length is $\operatorname{length} M' + \operatorname{length} M''$. For the long sequence, cut it into short exact sequences $0 \to Z_i \to M_i \to Z_{i+1} \to 0$ with Z_i the images, and add. (iv) A simple module is Rs for any $s \ne 0$, so $\simeq R/\operatorname{Ann}(s)$ with $\operatorname{Ann}(s)$ maximal (Proposition 3.4), hence $\simeq k$. A module killed by $\mathfrak{m}$ is a k-vector space whose R-submodules are its subspaces, so its length is its dimension; apply (iii) to the filtration $M \supseteq \mathfrak{m}M \supseteq \cdots \supseteq \mathfrak{m}^N M = 0$. If R is Noetherian and M finitely generated, the $\mathfrak{m}^i M/\mathfrak{m}^{i+1}M$ are finitely generated over k, which gives one direction. Conversely if $\operatorname{length} M = n$, the chain $(\mathfrak{m}^i M)_i$ has at most n strict steps, so $\mathfrak{m}^j M = \mathfrak{m}^{j+1}M$ for some j, and $\mathfrak{m}^j M = 0$ by Nakayama. (v) By (iii) along an R'-composition series it suffices to treat the simple R'-module k'. It is killed by $\mathfrak{m}_R$, so by (iv) its R-length is $\dim_k k' = f$, which is finite as k' is a quotient of the finitely generated R-module R'. □

For finite abelian groups the theorem is the statement that the prime factorisation of the order can be read off any composition series. In $\mathbb{Z}/12$ the chains $0 \subset 6\mathbb{Z}/12 \subset 2\mathbb{Z}/12 \subset \mathbb{Z}/12$ and $0 \subset 4\mathbb{Z}/12 \subset 2\mathbb{Z}/12 \subset \mathbb{Z}/12$ have factors $\mathbb{Z}/2, \mathbb{Z}/3, \mathbb{Z}/2$ and $\mathbb{Z}/3, \mathbb{Z}/2, \mathbb{Z}/2$: the same multiset, in a different order, and $\operatorname{length}_{\mathbb{Z}}(\mathbb{Z}/12) = 3$, the number of prime factors of 12 with multiplicity. Over $\mathbb{Z}_2$ the same group becomes $\mathbb{Z}/12 \otimes \mathbb{Z}_2 \simeq \mathbb{Z}/4$ (Theorem 3.58(v)), of length $2 = v_2(12)$: the

length over $\mathbb{Z}_\ell$ counts only the factors $\mathbb{Z}/\ell$. Part (v) is the reason for the factor f when lengths over a ring $\mathcal{O}_\lambda$ with residue field $\mathbb{F}_{\ell^f}$ are compared with lengths over $\mathbb{Z}_\ell$: the residue field $\mathbb{F}_{\ell^f}$, simple over $\mathcal{O}_\lambda$, has a composition series of length f over $\mathbb{Z}_\ell$.

Proposition 3.66 (length over a discrete valuation ring)**.** *Let $\mathcal{O}$ be a discrete valuation ring.*

(i) $\operatorname{length}(\mathcal{O}/\varpi^a) = a$. *A finitely generated $\mathcal{O}$-module has finite length if and only if it is torsion, and then* $\operatorname{length}(\bigoplus_i \mathcal{O}/\varpi^{a_i}) = \sum_i a_i$.

(ii) If k is finite, $\#M = (\#k)^{\operatorname{length}_{\mathcal{O}} M}$. Over $\mathbb{Z}_\ell$, $\operatorname{length}_{\mathbb{Z}_\ell}(M) = v_\ell(\#M)$ for finite M; over a ring $\mathcal{O}_\lambda$ with residue field $\mathbb{F}_{\ell^f}$ (finite over $\mathbb{Z}_\ell$), $v_\ell(\#M) = f \operatorname{length}_{\mathcal{O}_\lambda}(M)$.

(iii) For a finite-length $\mathcal{O}$-module M and $k \geq 0$, $\operatorname{length} M[\varpi^k] = \operatorname{length} M/\varpi^k M$.

For example, $\operatorname{length}_{\mathbb{Z}_\ell}(\mathbb{Z}/\ell^v \oplus \mathbb{Z}/\ell^m) = v + m$ *and* $\operatorname{length}_{\mathbb{Z}_\ell}(\mathbb{Z}_\ell/n'\mathbb{Z}_\ell) = v_\ell(n')$ *for $n' \in \mathbb{Z}_\ell \setminus \{0\}$.*

Proof. (i) $0 \subsetneq \varpi^{a-1}\mathcal{O}/\varpi^a \subsetneq \cdots \subsetneq \mathcal{O}/\varpi^a$ has factors $\simeq k$. $\mathcal{O}$ itself has the infinite chain $\varpi^i\mathcal{O}$, so it has infinite length (Theorem 3.65(i)); now use Proposition 3.57(i) and additivity. (ii) Orders are multiplicative in exact sequences and $\#k$ is the order of each factor; for $\mathcal{O}_\lambda$ use Theorem 3.65(v). (iii) The sequence $0 \to M[\varpi^k] \to M \xrightarrow{\varpi^k} M \to M/\varpi^k M \to 0$ is exact; apply Theorem 3.65(iii). □

Definition 3.67 (annihilators)**.** $\operatorname{Ann}_R(M) = \{r \in R : rM = 0\}$, an ideal; $\operatorname{Ann}_R(m)$ was defined in Proposition 3.4; for an ideal $\mathfrak{b}$ of a ring $\mathbb{T}$, $\operatorname{Ann}_{\mathbb{T}}(\mathfrak{b})$ is the annihilator of $\mathfrak{b}$ viewed as a $\mathbb{T}$-module. "M is killed by η" means $\eta \subseteq \operatorname{Ann}(M)$.

Proposition 3.68. *(i)* $\operatorname{Ann}(R/\mathfrak{a}) = \mathfrak{a}$; $\operatorname{Ann}(M \oplus N) = \operatorname{Ann}(M) \cap \operatorname{Ann}(N)$; *for generators $m_1, \ldots, m_n$,* $\operatorname{Ann}(M)$ *is the kernel of $R \to M^n$, $r \mapsto (rm_i)$.*

(ii) $M[\mathfrak{a}] \simeq \operatorname{Hom}_R(R/\mathfrak{a}, M)$; $M[\mathfrak{a}] \cap M[\mathfrak{b}] = M[\mathfrak{a}+\mathfrak{b}]$; $M[\mathfrak{a}] + M[\mathfrak{b}] \subseteq M[\mathfrak{a}\cap\mathfrak{b}]$.

(iii) For a ring $\mathbb{T}$ and an ideal $\mathfrak{a}$, $\mathbb{T}[\mathfrak{a}] = \operatorname{Ann}_{\mathbb{T}}(\mathfrak{a})$; if $L \simeq \mathbb{T}^r$ as $\mathbb{T}$-modules, then $L[\mathfrak{a}] \simeq \operatorname{Ann}_{\mathbb{T}}(\mathfrak{a})^r$.

(iv) For a flat $R \to S$, finitely generated M and finitely generated $\mathfrak{a}$: $\operatorname{Ann}_S(M \otimes S) = \operatorname{Ann}_R(M)S$ *and* $M[\mathfrak{a}] \otimes S = (M \otimes S)[\mathfrak{a}S]$.

(v) Over a discrete valuation ring, $\operatorname{Ann}(\bigoplus_{i=1}^s \mathcal{O}/\varpi^{a_i}) = \varpi^{\max_i a_i}\mathcal{O}$ *(for $s \geq 1$), and* $\operatorname{Ann}(M) = 0$ *if M has a free summand.*

Proof. (i) r kills $R/\mathfrak{a}$ iff it kills the generator $1 + \mathfrak{a}$, iff $r \in \mathfrak{a}$. An element kills $M \oplus N$ iff it kills both summands. It kills M iff it kills each generator m_i, iff it lies in the kernel of $r \mapsto (rm_i)_i$. (ii) The first statement is Proposition 3.25(i). An element is killed by $\mathfrak{a}$ and by $\mathfrak{b}$ iff it is killed by every $a+b$, that is, by $\mathfrak{a}+\mathfrak{b}$. If m is killed by $\mathfrak{a}$ and m' by $\mathfrak{b}$, then $m+m'$ is killed by $\mathfrak{a}\cap\mathfrak{b}$, which lies in both. (Over a principal ideal domain the last inclusion is an equality for finitely generated M, as one checks on cyclic summands; in general it can be strict: for $R = k[x,y]$, $M = R/(x,y)^2$ with basis $1, x, y$, $\mathfrak{a} = (x)$ and $\mathfrak{b} = (y)$, one has $M[\mathfrak{a}] = M[\mathfrak{b}] = kx + ky$, while $\mathfrak{a}\cap\mathfrak{b} = (xy)$ kills all of M.) (iii) $\mathbb{T}[\mathfrak{a}]$ and $\operatorname{Ann}_{\mathbb{T}}(\mathfrak{a})$ are both the set of $t \in \mathbb{T}$ with $at = 0$ for all $a \in \mathfrak{a}$. For $L = \mathbb{T}^r$, an element $(t_1, \ldots, t_r)$ is killed by $\mathfrak{a}$ iff each coordinate is, so $L[\mathfrak{a}] = \operatorname{Ann}_{\mathbb{T}}(\mathfrak{a})^r$; an isomorphism $L \simeq \mathbb{T}^r$ of $\mathbb{T}$-modules carries $L[\mathfrak{a}]$ to $\mathbb{T}^r[\mathfrak{a}]$. (iv) is Proposition 3.29(iii). (v) ϖ^a kills $\mathcal{O}/\varpi^b$ iff $a \geq b$, so it kills the sum iff $a \geq \max_i b_i$; and $\mathcal{O}$ is torsion-free. □

Definition 3.69 (Fitting ideals)**.** Let M be a finitely generated R-module with generators $x = (x_1, \dots, x_n)$, and let $\mathrm{Rel}(x) = \{r \in R^n : \sum r_i x_i = 0\}$ be the module of relations (row vectors). The (zeroth) *Fitting ideal* $\mathrm{Fitt}_R(M)$ is the ideal generated by the determinants $\det(r^{(1)}, \dots, r^{(n)})$ of all n-tuples of relations (the $n \times n$ matrices with these rows). If $R^m \xrightarrow{A} R^n \to M \to 0$ is a presentation (Convention 3.1(g)), $\mathrm{Fitt}_R(M)$ is the ideal generated by the $n \times n$ minors of A (and is 0 if $m < n$); see Lemma 3.70. More generally $\mathrm{Fitt}_i(M)$ is generated by the $(n-i) \times (n-i)$ minors; we use only $\mathrm{Fitt} = \mathrm{Fitt}_0$.

The Fitting ideal is an ideal-valued replacement for the order of a finite abelian group. For a finite abelian group with a square presentation matrix A, the order is $|\det A|$ (Theorem 3.50), and $\mathrm{Fitt}_{\mathbb{Z}}(M) = (\det A) = \#M \cdot \mathbb{Z}$. Over a general ring there is no order to take, and a presentation need not be square, so one takes all maximal minors at once. The definition through determinants of n-tuples of relations, rather than through a fixed matrix, is what makes independence of the choices provable. A small check: $\mathbb{Z}/6$ with the single generator 1 has relations $6\mathbb{Z}$, so $\mathrm{Fitt} = (6)$. With the two generators $x_1 = 2$, $x_2 = 3$, a pair (a, b) is a relation iff $2a + 3b \equiv 0 \pmod 6$, iff $3 \mid a$ and $2 \mid b$; so the relations are generated by $(3, 0)$ and $(0, 2)$, and the ideal of 2×2 minors is again (6), as Lemma 3.70 guarantees.

Lemma 3.70 (the Fitting ideal is well defined)**.** *(i) If the rows of $A \in \mathrm{M}_{m\times n}(R)$ generate $\mathrm{Rel}(x)$, the ideal of $n \times n$ minors of A equals the ideal $F(x)$ generated by the determinants of n-tuples of relations.*

(ii) $F(x)$ does not depend on the generating family x.

Proof. (i) Every $n \times n$ minor of A is the determinant of n relations. Conversely, if $r^{(i)} = \sum_j c_{ij} a_j$ with a_j the rows of A, then by multilinearity

$$\det(r^{(1)}, \dots, r^{(n)}) = \sum_{j_1, \dots, j_n} c_{1j_1} \cdots c_{nj_n} \det(a_{j_1}, \dots, a_{j_n}),$$

and each term is 0 (two equal rows) or $\pm$ a minor of A. (ii) Permuting the generators permutes the columns of the relation matrices and changes determinants by a sign. Next let $x' = (x_1, \dots, x_n, y)$ with $y = \sum_i a_i x_i$. If the rows of A generate $\mathrm{Rel}(x)$, then $\mathrm{Rel}(x')$ is generated by the rows $(r, 0)$, r a row of A, and the row $(-a_1, \dots, -a_n, 1)$: given $(s, t) \in \mathrm{Rel}(x')$, subtracting t times the last row leaves $(s + ta, 0)$ with $s + ta \in \mathrm{Rel}(x)$. An $(n+1) \times (n+1)$ minor of this matrix that omits the last row has a zero last column; one that contains it equals, expanding along the last column, $\pm$ an $n \times n$ minor of A, and every such minor occurs. By (i), $F(x') = F(x)$. Finally, for two generating families x and $z = (z_1, \dots, z_p)$, add the z_j to x one at a time (each is a combination of the x_i, hence of the current family), and the x_i to z likewise; both processes end at the same family up to order. So $F(x) = F(x \cup z) = F(z)$. □

Proposition 3.71 (properties of Fitting ideals)**.** *Let M, N be finitely generated.*

(i) $\mathrm{Fitt}(R/\mathfrak{a}) = \mathfrak{a}$; $\mathrm{Fitt}(0) = R$; $\mathrm{Fitt}(R^n) = 0$ *for* $n \geq 1$.

(ii) $\mathrm{Fitt}(M \oplus N) = \mathrm{Fitt}(M)\,\mathrm{Fitt}(N)$.

(iii) If $M \twoheadrightarrow N$ *then* $\mathrm{Fitt}(M) \subseteq \mathrm{Fitt}(N)$.

(iv) $\mathrm{Fitt}(M) \subseteq \mathrm{Ann}(M)$, *and* $\mathrm{Ann}(M)^n \subseteq \mathrm{Fitt}(M)$ *if M is generated by n elements.*

(v) $\mathrm{Fitt}_S(S\otimes_R M)=\mathrm{Fitt}_R(M)S$ *for every ring homomorphism* $R\to S$ *(no flatness is needed).*

(vi) For an exact sequence $0\to M'\to M\to M''\to 0$ *with* M' *finitely generated (automatic if* R *is Noetherian, Proposition 3.31(ii)),* $\mathrm{Fitt}(M')\,\mathrm{Fitt}(M'')\subseteq\mathrm{Fitt}(M)$*. Equality can fail: over* $R=\mathbb{Z}[x]$*, with* $M=R/(4,x)\simeq\mathbb{Z}/4$*,* $M'=2M\simeq R/(2,x)$ *and* $M''=M/2M\simeq R/(2,x)$*, one has* $\mathrm{Fitt}(M)=(4,x)$ *but* $\mathrm{Fitt}(M')\,\mathrm{Fitt}(M'')=(2,x)^2=(4,2x,x^2)$*.*

(vii) Over a domain, $\mathrm{Fitt}(M)\neq 0$ *if and only if* M *is torsion.*

Proof. (i) $R/\mathfrak{a}$ has the generator 1 with relations $\mathfrak{a}$, and its 1×1 "determinants" generate $\mathfrak{a}$. For $M=0$ use the generator 0 with the relation (1). R^n with its basis has no nonzero relation. (ii) Use generators x of M and y of N; $\mathrm{Rel}(x,y)=\mathrm{Rel}(x)\oplus\mathrm{Rel}(y)$ is generated by the rows of $\mathrm{diag}(A,B)$, with A of size $m\times n$ and B of size $m'\times n'$. Consider $n+n'$ of these rows, j from the first block and j' from the second, so $j+j'=n+n'$. If $j>n$, the j rows from the first block are zero outside the first n columns, and the Laplace expansion along these j rows involves only $j\times j$ minors of them, each of which uses at least $j-n\geq 1$ of the last n' columns, where these rows vanish; so every such minor, and the determinant, is 0. Likewise if $j'>n'$; and since $j+j'=n+n'$, the only remaining case is $j=n$, $j'=n'$. If $j=n$ and $j'=n'$ the determinant is the product of an $n\times n$ minor of A and an $n'\times n'$ minor of B. So the ideal is $\mathrm{Fitt}(M)\,\mathrm{Fitt}(N)$. (iii) Generators of M map to generators of N, and relations among them in M remain relations in N. (iv) Let B be an $n\times n$ matrix of relations, so B kills the column x of generators; multiplying by the adjugate gives $\det(B)x_i=0$ for all i. For $a_1,\dots,a_n\in\mathrm{Ann}(M)$ the rows a_ie_i are relations, with determinant $a_1\cdots a_n$. (v) Tensoring the presentation gives a presentation of $S\otimes M$ with the image of the same matrix (Proposition 3.28). (vi) Let x' generate M' (viewed in M) and let $y\in M^{n''}$ lift generators of M''. For $r'\in\mathrm{Rel}(x')$, $(r',0)$ is a relation of (x',y); for $r''\in\mathrm{Rel}(\bar{y})$, $\sum r''_jy_j\in M'$, say $=\sum c_ix'_i$, and $(-c,r'')$ is a relation. The determinant of n' relations of the first kind followed by n'' of the second is block triangular, equal to $\det(r'\text{s})\det(r''\text{s})$. In the example: $M'=2\mathbb{Z}/4$ is killed by 2 and x, so it is $R/(2,x)$, as is $M/2M$; $\mathrm{Fitt}(R/(4,x))=(4,x)$ by (i); $(2,x)^2=(4,2x,x^2)$; and $x\notin(4,2x,x^2)$ (every element of that ideal has the coefficient of x even). (vii) If M is torsion, $\mathrm{Ann}(M)\neq 0$ (the product of nonzero annihilators of the generators), so $\mathrm{Fitt}(M)\supseteq\mathrm{Ann}(M)^n\neq 0$. If not, $M\otimes K\simeq K^r$ with $r\geq 1$ (Proposition 3.46(i)), and $\mathrm{Fitt}(M)K=\mathrm{Fitt}_K(K^r)=0$ by (i) and (v). □

Theorem 3.72 (Fitting ideals and length)**.** *(i) Over a principal ideal domain, the module* $M=R^r\oplus\bigoplus_i R/(d_i)$ *has* $\mathrm{Fitt}(M)=0$ *if* $r>0$*, and* $\mathrm{Fitt}(M)=(\prod_i d_i)$ *if* $r=0$*.*

(ii) Over a discrete valuation ring $\mathcal{O}$*, every finitely generated torsion module* M *has* $\mathrm{Fitt}_{\mathcal{O}}(M)=\varpi^{\mathrm{length}(M)}\mathcal{O}$*, so* $v(\mathrm{Fitt}\,M)=\mathrm{length}\,M$*. Over* $\mathbb{Z}_\ell$*:* $\mathrm{Fitt}_{\mathbb{Z}_\ell}(M)=\#M\cdot\mathbb{Z}_\ell=\ell^{v_\ell(\#M)}\mathbb{Z}_\ell$ *for finite* M*.*

(iii) Consequently, over a discrete valuation ring Fitting ideals of finite-length modules are multiplicative in short exact sequences, and $\mathrm{Fitt}(N)\supseteq\mathrm{Fitt}(M)$ *for every submodule or quotient* N *of* M*.*

(iv) The Fitting ideal is not the annihilator: $(\mathbb{Z}/\ell)^2$ *and* $\mathbb{Z}/\ell^2$ *both have Fitting ideal* $\ell^2\mathbb{Z}_\ell$*, with annihilators* $\ell\mathbb{Z}_\ell$ *and* $\ell^2\mathbb{Z}_\ell$*.*

Proof. (i) By Proposition 3.71(i), (ii). (ii) By (i), $\mathrm{Fitt}(\bigoplus\mathcal{O}/\varpi^{a_i})=\varpi^{\sum a_i}\mathcal{O}$, and $\sum a_i=\mathrm{length}\,M$ (Proposition 3.66). Over $\mathbb{Z}_\ell$, $\#M=\ell^{\mathrm{length}\,M}$. (iii) For $0\to M'\to M\to M''\to 0$ of finite length, additivity of length (Theorem 3.65(iii)) gives $\varpi^{\mathrm{length}\,M}=\varpi^{\mathrm{length}\,M'}\varpi^{\mathrm{length}\,M''}$, that is,

$\mathrm{Fitt}(M) = \mathrm{Fitt}(M')\,\mathrm{Fitt}(M'')$ by (ii). A submodule or quotient N of M has length $N \le$ length M, again by additivity, so $\mathrm{Fitt}(N) = \varpi^{\text{length } N}\mathcal{O} \supseteq \varpi^{\text{length } M}\mathcal{O} = \mathrm{Fitt}(M)$. (iv) By (ii), $\mathrm{Fitt} = \ell^2\mathbb{Z}_\ell$ for both modules, as both have length 2; the annihilators are given by Proposition 3.68(v). □

Warning 3.73. Over $\mathbb{Z}_\ell$ the Fitting ideal of a finite module sees its whole order, while the annihilator sees only its exponent. The Tamagawa factor is a Fitting ideal; reading it as an annihilator would replace $v_\ell(n) + \min(\dots)$ in Lemma lem:tamfactor by $\max(v_\ell(n), \min(\dots)) = v_\ell(n)$. Over a general ring the Fitting ideal is not determined by lengths either (Proposition 3.71(vi)).

Example 3.74. Over $\mathbb{Z}$ (relations as rows), and then over $\mathbb{Z}_3$ and $\mathbb{Z}_\ell$; all entries were computed by hand and the Smith forms checked with PARI (Example 3.42).

relations	module	Fitt	Ann
rows $(2,4)$, $(6,8)$	$\mathbb{Z}/2 \oplus \mathbb{Z}/4$	(8)	(4)
rows $(2,4,4)$, $(-6,6,12)$, $(10,-4,-16)$	$\mathbb{Z}/2 \oplus \mathbb{Z}/6 \oplus \mathbb{Z}/12$	(144)	(12)
rows $(3,6)$, $(9,3)$	$\mathbb{Z}/3 \oplus \mathbb{Z}/15$	(45)	(15)
the same over $\mathbb{Z}_3$	$\mathbb{Z}/3 \oplus \mathbb{Z}/3$	$9\mathbb{Z}_3$	$3\mathbb{Z}_3$

one generator, rows (2), (4)	$\mathbb{Z}/2$	(2)	(2)
over $\mathbb{Z}[x]$: one generator, rows (2), (x)	$\mathbb{Z}[x]/(2,x)$	$(2,x)$	$(2,x)$
over $\mathbb{Z}[x]$: the square of the previous	$(\mathbb{Z}[x]/(2,x))^2$	$(4,2x,x^2)$	$(2,x)$
over $\mathbb{Z}_\ell$: the paper's module	$\mathbb{Z}/\ell^v \oplus \mathbb{Z}/\ell^m$	$\ell^{v+m}\mathbb{Z}_\ell$	$\ell^{\max(v,m)}\mathbb{Z}_\ell$
$\ell = 3$, $v = 2$, $m = 1$	$\mathbb{Z}/9 \oplus \mathbb{Z}/3$	$27\mathbb{Z}_3$	$9\mathbb{Z}_3$

In the fifth row the three 2×2 minors are 24, 12, -8, with gcd 4, although there are more relations than generators. In the eighth row the four relation rows $(2,0)$, $(x,0)$, $(0,2)$, $(0,x)$ have 2×2 minors $0, 4, 2x, 2x, x^2, 0$, and the Fitting ideal $(2,x)^2$ is strictly smaller than the annihilator, as Proposition 3.71(iv) allows.

In the paper 3.75. Section 1.2 defines $\mathrm{Tam}_p(M) = \mathrm{Fitt}_{\mathbb{Z}_\ell}((H^1(I_p, M)_{\mathrm{tor}})^{G_{\mathbb{Q}_p}})$, the Fitting ideal *of the invariants* (Appendix B, convention B-C10). This is a finite $\mathbb{Z}_\ell$-module, so by Theorem 3.72(ii) $v_\ell(\mathrm{Tam}_p(M))$ is its length. In Lemma lem:tamfactor the invariants are the $x\bar{e} + y\bar{h}$ in $(\mathbb{Z}/\ell^{v_\ell(n)})\bar{e} \oplus (\mathbb{Z}/\ell^{v_\ell(n)})\bar{h}$ with $(q-1)y \equiv 0$ and $c'y \equiv 0$, a module isomorphic to $\mathbb{Z}/\ell^{v_\ell(n)} \oplus \mathbb{Z}/\ell^{\min(v_\ell(n), v_\ell(q-1), v_\ell(c'))}$, of length $v_\ell(n) + \min(v_\ell(n), v_\ell(q-1), v_\ell(c'))$: this is the count in the paper's proof, where $v_\ell(c')$ may be replaced by $v_\ell(c(u))$, and the Fitting ideal of $\mathbb{Z}/\ell^v \oplus \mathbb{Z}/\ell^m$ is $\ell^{v+m}\mathbb{Z}_\ell$ by the last rows of Example 3.74. In Lemma lem:fpr the identity of Fitting ideals is an identity of lengths, $\text{length}\, H^1_f(\mathbb{Q}_p, T^D) = v_\ell(L_p(A_f,1)^{-1}) + v_\ell(\mathrm{Tam}_p(T^D))$, which is how the proof of Theorem thm:main uses it. The definitions of Tam_p and H^1_f are Chapter 18.

3.8 Pontryagin duality

Lemma lem:dfg21 is an exact sequence

$$0 \to H^1_f(\mathbb{Q}, W) \to H^1_\Sigma(\mathbb{Q}, W) \to \bigoplus_{p \in \Sigma \cup \{\infty\}} H^1_f(\mathbb{Q}_p, T^D)^* \to H^0(\mathbb{Q}, W^D)^* \to 0$$

in which * is the Pontryagin dual, and the proof of Theorem thm:main adds lengths along it. This needs two facts proved here: Pontryagin duality is exact, and it preserves the length of finite

modules. The coefficient module $W = \mathrm{ad}^0 T \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$ is the basic example of a discrete module dual to a finitely generated one (Proposition 3.78), and Lemma lem:h0 identifies $H^0(\mathbb{Q}, W^D)$ by its ℓ^k-torsion, using $W[\ell^k] = T/\ell^k T$ and the cyclicity criterion Corollary 3.79.

Theorem 3.76 (Pontryagin duality for finite abelian groups)**.** *For a finite abelian group A let $A^* = \mathrm{Hom}(A, \mathbb{Q}/\mathbb{Z})$.*

(i) $(\mathbb{Z}/n)^* \simeq \mathbb{Z}/n$, *and* $A^* \simeq A$ *(non-canonically).*

(ii) The evaluation map $A \to A^{**}$, $a \mapsto (\xi \mapsto \xi(a))$, is an isomorphism.

(iii) $A \mapsto A^*$ is an exact contravariant functor, and $\#A^* = \#A$.

(iv) For a subgroup $B \subseteq A$ let $B^\perp = \{\xi \in A^* : \xi(B) = 0\}$. Then $B^\perp \simeq (A/B)^*$ and $B^* \simeq A^*/B^\perp$, and $B \mapsto B^\perp$ is an inclusion-reversing bijection between the subgroups of A and those of A^*.

(v) If A is ℓ-primary, then $A^* = \mathrm{Hom}_{\mathbb{Z}_\ell}(A, \mathbb{Q}_\ell/\mathbb{Z}_\ell)$ and $\mathrm{length}_{\mathbb{Z}_\ell} A^* = \mathrm{length}_{\mathbb{Z}_\ell} A$; dualising an exact sequence of finite $\mathbb{Z}_\ell$-modules gives an exact sequence with the arrows reversed.

(vi) Via $x \mapsto e^{2\pi i x}$, A^* is the group of characters $A \to \mathbb{C}^\times$ (Chapter 2); in the language of Riley, Hobson and Bence, Pontryagin duality is the discrete Fourier transform on A.

Proof. (i) $\mathrm{Hom}(\mathbb{Z}/n, \mathbb{Q}/\mathbb{Z}) \simeq (\mathbb{Q}/\mathbb{Z})[n] = \frac{1}{n}\mathbb{Z}/\mathbb{Z} \simeq \mathbb{Z}/n$ by Proposition 3.25(i); and A is a finite direct sum of cyclic groups (Chapter 1), and Hom turns finite sums into sums. (ii) Injectivity: for $a \neq 0$ of order d, the map $\langle a \rangle \to \mathbb{Q}/\mathbb{Z}$, $a \mapsto 1/d$, extends to A because $\mathbb{Q}/\mathbb{Z}$ is injective (Proposition 3.60(iv)); so some ξ has $\xi(a) \neq 0$. Both sides have order $\#A$ by (i). (iii) Exactness is the injectivity of $\mathbb{Q}/\mathbb{Z}$: $\mathrm{Hom}(-, \mathbb{Q}/\mathbb{Z})$ is left exact by Proposition 3.25(ii), and surjectivity of $A^* \to B^*$ for $B \subseteq A$ is the statement that characters of B extend to A (Lemma 3.59). $\#A^* = \#A$ is (i). (iv) The exact sequence $0 \to B \to A \to A/B \to 0$ dualises to $0 \to (A/B)^* \to A^* \to B^* \to 0$, with the image of the first map equal to $B^\perp$. Hence $\#B^\perp = \#A/\#B$. Under $A = A^{**}$, $B \subseteq (B^\perp)^\perp$ and $\#(B^\perp)^\perp = \#A^*/\#B^\perp = \#B$, so $B = (B^\perp)^\perp$; and symmetrically for subgroups of A^*. (v) A is killed by some ℓ^k, so every homomorphism lands in $(\mathbb{Q}/\mathbb{Z})[\ell^k] \subseteq (\mathbb{Q}/\mathbb{Z})[\ell^\infty] = \mathbb{Q}_\ell/\mathbb{Z}_\ell$ (Proposition 3.60(i)); it is $\mathbb{Z}_\ell$-linear because $\mathbb{Z}_\ell$ acts on a module killed by ℓ^k through $\mathbb{Z}/\ell^k$. Lengths agree because orders do (Proposition 3.66(ii)). (vi) $x \mapsto e^{2\pi i x}$ is an isomorphism from $\mathbb{Q}/\mathbb{Z}$ onto the roots of unity in $\mathbb{C}^\times$. □

For $A = \mathbb{Z}/n$ the duality is explicit: the character ξ_a with $\xi_a(1) = a/n + \mathbb{Z}$ corresponds to $a \in \mathbb{Z}/n$, and in the language of (vi) it is $x \mapsto e^{2\pi i a x/n}$, the a-th Fourier mode. For the subgroup $B = d\mathbb{Z}/n\mathbb{Z}$ (with $d \mid n$), $B^\perp$ consists of the ξ_a with $ad/n \in \mathbb{Z}$, that is, $a \in (n/d)\mathbb{Z}/n\mathbb{Z}$, a group of order $d = \#(A/B)$, as (iv) predicts. The isomorphism $A \simeq A^*$ depends on the choice of the generator, whereas the double duality $A \simeq A^{**}$ of (ii) is canonical and therefore compatible with any group action on A; only the canonical statements survive when A carries a Galois action.

Theorem 3.77 (Pontryagin duality for $\mathbb{Z}_\ell$-modules)**.** *Let $\mathcal{C}$ be the category of finitely generated $\mathbb{Z}_\ell$-modules and $\mathcal{D}$ that of ℓ-primary torsion $\mathbb{Z}_\ell$-modules W with $W[\ell]$ finite (*cofinitely generated *modules), with the discrete topology. For X in either, put $X^* = \mathrm{Hom}_{\mathbb{Z}_\ell}(X, \mathbb{Q}_\ell/\mathbb{Z}_\ell)$. (For $M \in \mathcal{C}$ every such homomorphism is continuous for the ℓ-adic topology, since its image is a finitely generated, hence finite, submodule of $\mathbb{Q}_\ell/\mathbb{Z}_\ell$, killed by some ℓ^k; so the homomorphism kills the open submodule $\ell^k M$.) For $W \in \mathcal{D}$, $W^* = \varprojlim_k (W[\ell^k])^*$ along the restriction maps, and we give*

it this inverse-limit topology, which is profinite; by (ii) below W^* is finitely generated, and the topology is its ℓ-adic one, because $\ell^k W^*$ kills $W[\ell^k]$ and a continuous bijection from a compact space onto a Hausdorff space is a homeomorphism.

(i) $\mathbb{Z}_\ell^* = \mathbb{Q}_\ell/\mathbb{Z}_\ell$, $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)^* = \mathbb{Z}_\ell$, *and* $(\mathbb{Z}/\ell^a)^* \simeq \mathbb{Z}/\ell^a$.

(ii) $X \mapsto X^*$ *is exact, maps* $\mathcal{C}$ *to* $\mathcal{D}$ *and* $\mathcal{D}$ *to* $\mathcal{C}$, *and the evaluation maps* $M \to M^{**}$, $W \to W^{**}$ *are isomorphisms.*

(iii) Every $W \in \mathcal{D}$ *is isomorphic to* $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r \oplus F$ *with* F *finite;* r, *the* corank *of* W, *equals* $\operatorname{rank}_{\mathbb{Z}_\ell} W^*$. W *is finite iff* $r = 0$, *and divisible iff* $F = 0$.

(iv) Lengths of finite modules are preserved: $\operatorname{length} X^* = \operatorname{length} X$.

(v) More generally, $X \mapsto \operatorname{Hom}_{\mathrm{cont}}(X, \mathbb{Q}_\ell/\mathbb{Z}_\ell)$ *is an exact anti-equivalence between compact and discrete* ℓ*-primary* $\mathbb{Z}_\ell$*-modules (stated; see [143, Chapter I, Section 1]).*

Proof. (iii) first. By induction $W[\ell^{k+1}]$ is finite: multiplication by ℓ maps it to $W[\ell^k]$ with kernel $W[\ell]$. Let $D = \bigcap_k \ell^k W$. *D is divisible.* Let $x \in D$; for each k write $x = \ell^{k+1} w_k$ and put $y_k = \ell^k w_k$, so $\ell y_k = x$ and $y_k \in \ell^k W$. The y_k all lie in the finite set $y_0 + W[\ell]$, so one value y occurs for infinitely many k; then $y \in \ell^k W$ for all k, so $y \in D$ and $\ell y = x$. Divisibility by units is automatic. $D \simeq (\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r$, $r = \dim_{\mathbb{F}_\ell} D[\ell]$. Choose an isomorphism $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r[\ell] \simeq D[\ell]$ and extend it to $\phi\colon (\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r \to D$ using the injectivity of D (Lemma 3.59). The kernel of ϕ has no ℓ-torsion, and an ℓ-primary module without ℓ-torsion is 0; so ϕ is injective. Its image is divisible, hence injective, hence a direct summand: $D = \phi((\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r) \oplus C$, where $C[\ell] = 0$ because $D[\ell]$ lies in the image; so $C = 0$. *$W = D \oplus F$ with F finite.* D is injective, so $W = D \oplus F$. Then $\ell^k W = D \oplus \ell^k F$, so $\bigcap_k \ell^k F = 0$. The subgroups $\ell^k F \cap F[\ell]$ of the finite group $F[\ell]$ decrease and have intersection 0, so $\ell^k F \cap F[\ell] = 0$ for some k; then $\ell^k F$ has no ℓ-torsion, so $\ell^k F = 0$, and $F = F[\ell^k]$ is finite. W is finite iff $r = 0$; it is divisible iff $F = 0$ (a finite divisible ℓ-primary module is 0). (i) $\operatorname{Hom}(\mathbb{Z}_\ell, X) = X$; $\operatorname{End}(\mathbb{Q}_\ell/\mathbb{Z}_\ell) = \mathbb{Z}_\ell$ and $\operatorname{Hom}(\mathbb{Z}/\ell^a, \mathbb{Q}_\ell/\mathbb{Z}_\ell) \simeq \mathbb{Z}/\ell^a$ (Proposition 3.60(iii)). (ii) Exactness: $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ is injective (Proposition 3.60(iv)). By Proposition 3.57(i) and (iii) above, every object of $\mathcal{C}$ or $\mathcal{D}$ is a finite direct sum of copies of $\mathbb{Z}_\ell$, $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ and $\mathbb{Z}/\ell^a$, and by (i) duality exchanges $\mathbb{Z}_\ell$ and $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ and preserves $\mathbb{Z}/\ell^a$. The evaluation map is natural and compatible with finite sums, so it suffices to check it on these three modules: for $\mathbb{Z}_\ell$, identify $\mathbb{Z}_\ell^* = \mathbb{Q}_\ell/\mathbb{Z}_\ell$ by $\xi \mapsto \xi(1)$; then the evaluation at $a \in \mathbb{Z}_\ell$ is multiplication by a on $\mathbb{Q}_\ell/\mathbb{Z}_\ell$, which is the element a of $\operatorname{End}(\mathbb{Q}_\ell/\mathbb{Z}_\ell) = \mathbb{Z}_\ell$. For $\mathbb{Q}_\ell/\mathbb{Z}_\ell$, identify $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)^* = \mathbb{Z}_\ell$; the evaluation at x is $a \mapsto ax$, which is the element x of $\operatorname{Hom}(\mathbb{Z}_\ell, \mathbb{Q}_\ell/\mathbb{Z}_\ell) = \mathbb{Q}_\ell/\mathbb{Z}_\ell$. For $\mathbb{Z}/\ell^a$ it is Theorem 3.76(ii). Finally $\operatorname{rank}_{\mathbb{Z}_\ell} W^* = r$ by the decomposition. (iv) is Theorem 3.76(v). (v) We do not prove this. □

Proposition 3.78 (the duality between T and $T \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$)**.** *Let T be a free $\mathbb{Z}_\ell$-module of rank r, $V = T \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$ and $W = T \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell$.*

(i) $0 \to T \to V \to W \to 0$ *is exact, and* $W \simeq (\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r$ *is divisible of corank r.*

(ii) $W[\ell^k] \simeq T/\ell^k T$, *by* $t \otimes \ell^{-k} \mapsto t \bmod \ell^k$. *Under these isomorphisms the inclusion* $W[\ell^k] \subseteq W[\ell^{k+1}]$ *becomes multiplication by* $\ell\colon T/\ell^k \to T/\ell^{k+1}$, *and multiplication by* $\ell\colon W[\ell^{k+1}] \to W[\ell^k]$ *becomes reduction* $T/\ell^{k+1} \to T/\ell^k$.

(iii) $T \simeq \varprojlim_k W[\ell^k]$, *the transition maps being multiplication by ℓ: T is the* Tate module *of W.*

(iv) $W^* = \mathrm{Hom}(T \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell, \mathbb{Q}_\ell/\mathbb{Z}_\ell) \simeq \mathrm{Hom}_{\mathbb{Z}_\ell}(T, \mathrm{End}(\mathbb{Q}_\ell/\mathbb{Z}_\ell)) = \mathrm{Hom}_{\mathbb{Z}_\ell}(T, \mathbb{Z}_\ell) = T^\vee$, *and* $T^* \simeq T^\vee \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$.

(v) Everything is functorial in T*: a group acting* $\mathbb{Z}_\ell$*-linearly on* T *acts on* V, W, $W[\ell^k] = T/\ell^k T$ *compatibly with the maps above, and on duals by* $(g\xi)(x) = \xi(g^{-1}x)$.

(vi) The same holds over any complete discrete valuation ring $\mathcal{O}$ *with fraction field* K*, with* $K/\mathcal{O}$ *in place of* $\mathbb{Q}_\ell/\mathbb{Z}_\ell$.

Proof. (i) Tensor the exact sequence $0 \to \mathbb{Z}_\ell \to \mathbb{Q}_\ell \to \mathbb{Q}_\ell/\mathbb{Z}_\ell \to 0$ with the free, hence flat, module T. (ii) Apply Corollary 3.16(a) with $n = \ell^k$: $V[\ell^k] = 0$ and $V/\ell^k V = 0$, so the connecting map $W[\ell^k] \to T/\ell^k T$ is an isomorphism. It sends the class of $v \in V$ (with $\ell^k v \in T$) to $\ell^k v \bmod \ell^k T$, which on $t \otimes \ell^{-k}$ is $t \bmod \ell^k$. If w is the class of v with $\ell^k v = t$, then in $W[\ell^{k+1}]$ it corresponds to $\ell^{k+1}v = \ell t$; and ℓw, the class of ℓv, corresponds in $W[\ell^k]$ to $\ell^k(\ell v) = \ell^{k+1}v$ reduced modulo ℓ^k. (iii) By (ii) the system $(W[\ell^k], \cdot\ell)$ is $(T/\ell^k T, \text{reduction})$, whose limit is T (Theorem 3.58(vi)). (iv) The adjunction (Theorem 3.26(iii)) and Proposition 3.60(iii). For the second, the canonical map $T^\vee \otimes X \to \mathrm{Hom}(T, X)$, $\varphi \otimes x \mapsto (t \mapsto \varphi(t)x)$, is an isomorphism for T free of finite rank (check on a basis). (v) All maps above are natural in T. (vi) The proofs use only that $\mathcal{O}$ is a discrete valuation ring, that $K/\mathcal{O}$ is divisible (hence injective, Lemma 3.59), and, for (iii) and (iv), completeness of $\mathcal{O}$: $\mathrm{End}_{\mathcal{O}}(K/\mathcal{O}) = \varprojlim \mathcal{O}/\varpi^k = \mathcal{O}$ as in Proposition 3.60(iii). □

Corollary 3.79. *An* ℓ*-primary torsion* $\mathbb{Z}_\ell$*-module* A *with* $\#A[\ell] \le \ell$ *is* 0, $\mathbb{Z}/\ell^h$ *for some* $h \ge 1$, *or* $\mathbb{Q}_\ell/\mathbb{Z}_\ell$*. If it is finite, its length is the largest* k *such that* A *has an element of exact order* ℓ^k.

Proof. $A \in \mathcal{D}$, so $A \simeq (\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r \oplus F$ by Theorem 3.77(iii), and $\dim_{\mathbb{F}_\ell} A[\ell] = r + \dim F[\ell] \le 1$. If $r = 1$ then $F[\ell] = 0$, so $F = 0$. If $r = 0$, F is finite with $\dim F[\ell] \le 1$, hence cyclic (Proposition 3.57(v)), $F \simeq \mathbb{Z}/\ell^h$, of length h, and an element of exact order ℓ^k exists iff $k \le h$. □

In the paper 3.80. In the proof of Theorem thm:main the paper takes lengths in the sequence of Lemma lem:dfg21. All four terms are finite there: $H^1_\Sigma(\mathbb{Q}, W)$ by Theorem thm:dfg37, the local terms $H^1_f(\mathbb{Q}_p, T^D)$ as torsion submodules of finitely generated $\mathbb{Z}_\ell$-modules (the paragraph after Lemma lem:dfg21), and $H^0(\mathbb{Q}, W^D)$ by Lemma lem:h0. By Theorem 3.77(iv) the duals have the same lengths, and by Theorem 3.65(iii)

$$\operatorname{length} H^1_\Sigma(\mathbb{Q}, W) = \operatorname{length} H^1_f(\mathbb{Q}, W) + \sum_{p \in \Sigma \cup \{\infty\}} \operatorname{length} H^1_f(\mathbb{Q}_p, T^D) - \operatorname{length} H^0(\mathbb{Q}, W^D),$$

which is the paper's display once $H^0(\mathbb{Q}, W^D) = 0$ and $H^1_f(\mathbb{R}, T^D) = 0$ (Paper link 3.63); Remark rem:ns keeps the term $\operatorname{length} H^0(\mathbb{Q}, W^D) = h_\ell(E)$. In Lemma lem:h0, $W^D = \mathrm{ad}^0 T(1) \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$, so $W^D[\ell^k] \simeq \mathrm{ad}^0 T(1)/\ell^k$ by Proposition 3.78(ii) (functorially, hence as Galois modules), which is the paper's "ℓ^k-torsion of $H^0(\mathbb{Q}, W^D)$ is $H^0(\mathbb{Q}, \mathrm{ad}^0(T/\ell^k)(1))$". The ℓ-torsion of $H^0(\mathbb{Q}, W^D)$ has $\mathbb{F}_\ell$-dimension at most one, so Corollary 3.79 shows that $H^0(\mathbb{Q}, W^D)$ is 0, cyclic of order ℓ^h, or $\mathbb{Q}_\ell/\mathbb{Z}_\ell$; the last is excluded by the determinant argument of the lemma, and $h_\ell(E)$ is the largest k for which an element of exact order ℓ^k exists.

Pontryagin duality pairs a module with its characters, with values in the torsion module $\mathbb{Q}_\ell/\mathbb{Z}_\ell$. The next section studies the other duality of the paper, $L \mapsto L^\vee = \mathrm{Hom}(L, \mathcal{O})$ for lattices, realised by a bilinear pairing with values in $\mathcal{O}$; the two are linked by Proposition 3.78(iv), $W^* \simeq T^\vee$, and by Proposition 3.51, where the cokernel of $M^\vee \hookrightarrow L^\vee$ is a Pontryagin dual.

3.9 Pairings: Gram determinants, saturated sublattices, alternating pairings, adjoints

The heart of Lemma lem:ddt417 is a statement about a perfect pairing on a lattice L and a saturated sublattice $L[\wp]$: "The pairing identifies $L/L[\wp]^{\perp}$ with $\mathrm{Hom}(L[\wp],\mathcal{O})$, because $L[\wp]$ is saturated", and "Q is the cokernel of $L[\wp]\to\mathrm{Hom}(L[\wp],\mathcal{O})$, of order $\#\mathcal{O}/\Delta$". Section 4.1 of the paper adds that the pairing $\hat{\delta}_!$ is perfect and alternating, that the Hecke operators are self-adjoint for it, and that "the Gram determinant of the pairing on $M_{f^\Sigma,\lambda}$ is $(\eta^{\Sigma}_{f,\lambda})^2$ up to a unit". Lemma lem:crit uses the pairing $S_2(\Gamma_0(N);\mathbb{Z})\times\mathbb{T}\to\mathbb{Z}$. This section proves each of these statements in the abstract. Throughout, except in Proposition 3.82, which holds over any commutative ring, R is a principal ideal domain (in practice $\mathbb{Z}$, $\mathbb{Z}_\ell$ or $\mathcal{O}$) with fraction field K, and pairings follow Convention 3.1(e). To a reader of Riley, Hobson and Bence a Gram matrix is a metric tensor $g_{ij}=\langle e_i,e_j\rangle$; the novelty is that over $\mathbb{Z}$ or $\mathbb{Z}_\ell$ the determinant is meaningful only up to units, and its valuation is what is measured.

Definition 3.81 (perfect pairings)**.** For a pairing $\langle\ ,\ \rangle\colon L\times M\to R$ let $\alpha\colon L\to M^\vee$, $x\mapsto\langle x,-\rangle$, and $\beta\colon M\to L^\vee$, $y\mapsto\langle -,y\rangle$. The pairing is *perfect* if α and β are isomorphisms and *nondegenerate* if they are injective. For free modules L, M of the same finite rank with bases (e_i), (f_j), the *Gram determinant* is $\Delta=\det(\langle e_i,f_j\rangle)$.

Proposition 3.82. *Let R be any commutative ring, L, M free R-modules of rank n and G the Gram matrix of a pairing $L\times M\to R$.*

(i) The pairing is perfect iff $\det G\in R^\times$, iff one of α, β is an isomorphism. If R is a domain, it is nondegenerate iff $\det G\neq 0$. For example, $\langle x,y\rangle=2xy$ on $\mathbb{Z}$ is nondegenerate and not perfect; over $\mathbb{Z}_\ell$ with ℓ odd it is perfect.

(ii) If the bases are changed by $e'=eP$, $f'=fQ$ (that is, $e'_j=\sum_i P_{ij}e_i$), then $G'=P^{\mathsf{T}}GQ$ and $\det G'=\det P\det Q\det G$; for $L=M$ with the same change of basis on both sides, $\det G'=(\det P)^2\det G$. So the ideal ΔR does not depend on the bases; over a discrete valuation ring $v(\Delta)$ is a basis-independent invariant.

(iii) Perfectness is preserved by base change: if $R\to S$ is a ring homomorphism, the S-bilinear extension to $(L\otimes S)\times(M\otimes S)$ has Gram matrix the image of G, so it is perfect if the original is.

Proof. (i) In the dual basis $(f_j^\vee)$, $\alpha(e_i)=\sum_j\langle e_i,f_j\rangle f_j^\vee$, so α has matrix G and β has matrix G^{T}, both of determinant $\det G$. Proposition 3.21(iii), valid over any commutative ring, gives the first claim; over a domain R with fraction field K, a square matrix is injective iff its determinant is nonzero (compute over K). (ii) $\langle e'_i,f'_j\rangle=\sum_{a,b}P_{ai}\langle e_a,f_b\rangle Q_{bj}$, and $\det P$, $\det Q$ are units. (iii) The elements $e_i\otimes 1$ and $f_j\otimes 1$ are bases of $L\otimes S$ and $M\otimes S$ (Theorem 3.26(iv)), and $\langle e_i\otimes 1,f_j\otimes 1\rangle$ is the image of $\langle e_i,f_j\rangle$ in S. The determinant of the image matrix is the image of $\det G$, and a ring homomorphism maps units to units; apply (i) over S. □

The example in (i) is the typical way in which perfectness depends on the coefficients: the Gram determinant 2 is a nonzero non-unit in $\mathbb{Z}$ and in $\mathbb{Z}_2$, and a unit in $\mathbb{Z}_\ell$ for ℓ odd. Over $\mathbb{Z}_\ell$ only $v_\ell(\Delta)$ matters, by (ii); this is the number that Lemma lem:ddt417 compares with the congruence ideal.

Proposition 3.83 (orthogonals)**.** *Let $\langle\ ,\ \rangle\colon L\times L\to R$ be a perfect pairing on a lattice of rank n, not necessarily symmetric.*

(i) For every subset S, $S^{\perp}$ and ${}^{\perp}S$ are saturated.

(ii) For a submodule N of rank d, $N^{\perp}$ and ${}^{\perp}N$ have rank $n-d$, and ${}^{\perp}(N^{\perp})=\operatorname{sat}(N)=({}^{\perp}N)^{\perp}$. In particular ${}^{\perp}(N^{\perp})=N=({}^{\perp}N)^{\perp}$ if N is saturated.

(iii) If the pairing is symmetric or antisymmetric, left and right orthogonals agree.

Proof. (i) If $ry\in S^{\perp}$ with $r\neq 0$, then $r\langle s,y\rangle=0$, so $\langle s,y\rangle=0$ for $s\in S$. (ii) Since $\langle rx,y\rangle=0$ iff $\langle x,y\rangle=0$ for $r\neq 0$, $N^{\perp}=\operatorname{sat}(N)^{\perp}$, and we may assume N saturated, hence a direct summand (Proposition 3.49). Then the map $L\to N^{\vee}$, $y\mapsto\langle -,y\rangle|_N$, is surjective: a functional on N extends by 0 on a complement to an element of $L^{\vee}$, which is $\langle -,y\rangle$ for some y because β is onto. Its kernel is $N^{\perp}$, so $\operatorname{rank}N^{\perp}=n-d$; likewise for ${}^{\perp}N$. Now ${}^{\perp}(N^{\perp})\supseteq N$, both are saturated (by (i)), and both have rank d; a saturated module containing another of the same rank equals its saturation (Proposition 3.49(ii)). The same argument with the roles of the two arguments exchanged gives $({}^{\perp}N)^{\perp}=\operatorname{sat}(N)$. (iii) If $\langle x,y\rangle=\pm\langle y,x\rangle$, then $\langle s,y\rangle=0$ iff $\langle y,s\rangle=0$, so the two orthogonals of any subset coincide. □

Theorem 3.84 (the Gram determinant of a saturated sublattice)**.** *Let $\mathcal{O}$ be a discrete valuation ring, L a lattice of rank n with a perfect pairing, $L'\subseteq L$ a* saturated *sublattice of rank d, and Δ the Gram determinant of the restriction of the pairing to $L'\times L'$ (in any basis).*

(i) The map $\rho\colon L\to\operatorname{Hom}_{\mathcal{O}}(L',\mathcal{O})=L'^{\vee}$, $y\mapsto\langle -,y\rangle|_{L'}$, is surjective with kernel $L'^{\perp}$; so $L/L'^{\perp}\simeq L'^{\vee}$.

(ii) If $\Delta\neq 0$, then $L'\cap L'^{\perp}=0$, the restriction $\rho|_{L'}\colon L'\to L'^{\vee}$ is injective, and

$$L/(L'\oplus L'^{\perp})\ \simeq\ \operatorname{coker}(L'\xrightarrow{\rho}L'^{\vee})\ \simeq\ \bigoplus_{i=1}^{d}\mathcal{O}/(\delta_i),$$

where the (δ_i) are the invariant factors of the Gram matrix of L'. Its length is $v(\Delta)$; when k is finite its order is $\#\mathcal{O}/\Delta\mathcal{O}=(\#k)^{v(\Delta)}$.

(iii) In (ii), $L'^{\perp}$ is saturated of rank $n-d$, and the Gram determinant $\Delta^{\perp}$ of the restriction of the pairing to $L'^{\perp}$ satisfies $v(\Delta^{\perp})=v(\Delta)$.

(iv) Saturation is necessary: in $L=\mathbb{Z}_\ell^2$ with the standard pairing $\langle x,y\rangle=x_1y_1+x_2y_2$, the sublattice $L'=\mathbb{Z}_\ell\cdot\ell e_1$ has $\Delta=\ell^2$, while $L/(L'\oplus L'^{\perp})=\mathbb{Z}_\ell^2/(\ell\mathbb{Z}_\ell\oplus\mathbb{Z}_\ell)\simeq\mathbb{Z}/\ell$ has length 1.

Proof. (i) is the surjectivity shown in the proof of Proposition 3.83(ii) (saturation makes L' a direct summand); the kernel is $L'^{\perp}$ by definition. (ii) In a basis of L' and the dual basis of $L'^{\vee}$, $\rho|_{L'}$ has matrix the transpose of the Gram matrix of L', of determinant $\Delta\neq 0$; so it is injective, and its kernel $L'\cap L'^{\perp}$ is 0. By (i), ρ induces $L/L'^{\perp}\simeq L'^{\vee}$, under which $(L'+L'^{\perp})/L'^{\perp}$ corresponds to $\rho(L')$; hence $L/(L'\oplus L'^{\perp})\simeq L'^{\vee}/\rho(L')$. By Theorem 3.41 this cokernel is $\bigoplus\mathcal{O}/(\delta_i)$ with $\prod\delta_i=\Delta$ up to a unit, of length $\sum v(\delta_i)=v(\Delta)$ (Proposition 3.66). (iii) $L'^{\perp}$ is saturated of rank $n-d$ by Proposition 3.83. If $\Delta^{\perp}=0$, some $0\neq y\in L'^{\perp}\otimes K$ is right-orthogonal to $L'^{\perp}\otimes K$; it is also right-orthogonal to $L'\otimes K$ (as $y\in L'^{\perp}\otimes K$); and $L'\otimes K+L'^{\perp}\otimes K=L\otimes K$ by (ii) (the quotient is torsion), so y is right-orthogonal to everything, contradicting perfectness.

So $\Delta^\perp \neq 0$. Apply (ii) to the transposed pairing $\langle x,y\rangle^{\mathsf T} = \langle y,x\rangle$, which is perfect, and to the saturated $N = L'^\perp$: its Gram determinant is $\Delta^\perp$ (transposed), its right orthogonal for the transposed pairing is the left orthogonal ${}^\perp(L'^\perp) = L'$ (Proposition 3.83(ii)), so $L/(L'^\perp \oplus L')$ has length $v(\Delta^\perp)$. It also has length $v(\Delta)$. (iv) $L'^\perp = \{y : \langle \ell e_1, y\rangle = \ell y_1 = 0\} = \mathbb{Z}_\ell e_2$, so $L' \oplus L'^\perp = \ell\mathbb{Z}_\ell e_1 \oplus \mathbb{Z}_\ell e_2$ and the quotient is $\mathbb{Z}_\ell/\ell\mathbb{Z}_\ell \simeq \mathbb{Z}/\ell$, of length 1; while $\Delta = \langle \ell e_1, \ell e_1\rangle = \ell^2$ has valuation 2. The proof of (ii) breaks at (i): the restriction map $\rho\colon L \to L'^\vee$ has image the functionals with $\ell e_1 \mapsto \ell y_1$, which is $\ell L'^\vee$, not $L'^\vee$. □

In words: for a saturated L', the pairing gives as much room as possible in the quotient $L/L'^\perp$, namely all of $L'^\vee$, and the failure of $L' \oplus L'^\perp$ to fill L is then measured exactly by how far L' is from being self-dual, which is what Δ measures. For a non-saturated L' the Gram determinant also records the index of L' in its saturation, twice (Exercise 3.124(a)).

Example 3.85. On $\mathbb{Z}^2$ take the Gram matrix $\begin{pmatrix} 9 & 1 \\ 1 & 0 \end{pmatrix}$ (perfect: determinant -1) and $L' = \mathbb{Z}e_1$, saturated, with $\Delta = 9$. Then $L'^\perp = \{y : 9y_1 + y_2 = 0\} = \mathbb{Z}(1,-9)$, and $L' \oplus L'^\perp$ has basis $(1,0)$, $(1,-9)$, so index $|\det \begin{pmatrix} 1 & 0 \\ 1 & -9 \end{pmatrix}| = 9 = \Delta$, as Theorem 3.84(ii) predicts; the Gram determinant on $L'^\perp$ is $\langle (1,-9),(1,-9)\rangle = 9 - 9 - 9 = -9$, of the same valuation. With the standard pairing and the non-saturated $L' = \mathbb{Z}\cdot 3e_1$ the Gram determinant is 9 but the index of $L' \oplus L'^\perp = 3\mathbb{Z} \oplus \mathbb{Z}$ is 3.

In the paper 3.86. In the proof of Lemma lem:ddt417, "The pairing identifies $L/L[\wp]^\perp$ with $\mathrm{Hom}(L[\wp], \mathcal{O})$, because $L[\wp]$ is saturated" is Theorem 3.84(i) with $L' = L[\wp]$, saturated by Proposition 3.49(iii); "Q is the cokernel of $L[\wp] \to \mathrm{Hom}(L[\wp], \mathcal{O})$, of order $\#\mathcal{O}/\Delta$" is part (ii), once $L[\wp]^\perp = L[I]$ is known (Proposition 3.113). Part (iv) shows that the word "saturated" cannot be dropped. For a residue field that is not finite the order must be read as the length $v(\Delta)$ (Convention 3.1(f)); the paper assumes k finite.

Proposition 3.87 (alternating pairings)**.** *A pairing $L \times L \to R$ is* alternating *if $\langle x,x\rangle = 0$ for all x. An alternating pairing is antisymmetric; conversely an antisymmetric pairing is alternating if 2 is a nonzerodivisor in R (for instance R a domain of characteristic 0).*

(i) The Gram matrix of an alternating pairing is antisymmetric with zero diagonal; its determinant vanishes in odd rank, so a perfect alternating pairing on a nonzero lattice has even rank. In even rank $\det G = \mathrm{Pf}(G)^2$ for a polynomial Pf in the entries (the Pfaffian); in rank 4, $\mathrm{Pf}(G) = g_{12}g_{34} - g_{13}g_{24} + g_{14}g_{23}$.

(ii) Rank two: $G = \begin{pmatrix} 0 & a \\ -a & 0 \end{pmatrix}$ with $a = \langle e_1, e_2\rangle$, so $\Delta = a^2$; and $\langle x,y\rangle = a(x_1y_2 - x_2y_1)$, so the ideal of values $\langle L,L\rangle = \{\langle x,y\rangle\}$ is aR. Hence, without reference to a basis, $\Delta R = (\text{ideal of values})^2$.

(iii) (Symplectic normal form.) Over a principal ideal domain an alternating pairing has a basis in which G is block diagonal with blocks $\begin{pmatrix} 0 & d_i \\ -d_i & 0 \end{pmatrix}$, $d_1 \mid d_2 \mid \cdots$, followed by zeros; it is perfect iff all d_i are units and there is no zero block.

Proof. $0 = \langle x+y, x+y\rangle = \langle x,y\rangle + \langle y,x\rangle$; conversely antisymmetry gives $2\langle x,x\rangle = 0$. (i) The diagonal entries are $\langle e_i, e_i\rangle = 0$. For odd n, let X be the generic alternating matrix over the

polynomial ring $\mathbb{Z}[x_{ij} : i < j]$; then $\det X = \det X^{\mathsf{T}} = \det(-X) = -\det X$, and as $\mathbb{Z}[x_{ij}]$ is a domain of characteristic 0, $\det X = 0$; specialising the variables gives $\det G = 0$ over any R. A perfect pairing has $\det G$ a unit, and units are nonzero when $R \neq 0$. The identity $\det G = \mathrm{Pf}(G)^2$ in general is classical and we do not prove it (see [109, Chapter XV, Section 9], section number not verified); in rank 4 it is a direct expansion, which we checked with PARI. (ii) Expand $\langle x_1 e_1 + x_2 e_2, y_1 e_1 + y_2 e_2\rangle$; the value $x_1 y_2 - x_2 y_1$ is 1 for $x = e_1$, $y = e_2$. □

Sketch of proof of (iii). Choose x, y with $\langle x, y\rangle = d_1$ a generator of the ideal of values (if it is 0 the pairing is zero). The map $z \mapsto z - \frac{\langle z,y\rangle}{d_1} x + \frac{\langle z,x\rangle}{d_1} y$ is defined over R because d_1 divides every value, and it projects L onto the orthogonal of $\{x, y\}$, giving $L = (Rx \oplus Ry) \oplus \{x, y\}^{\perp}$; induct, noting that the ideal of values only shrinks. See [109, Chapter XV, Section 8] (section number not verified). □

In the paper 3.88. Section 4.1: "The restriction of $\hat{\delta}_!$ to the rank-two lattice $M_{f^\Sigma,\lambda}$ takes its values in an ideal of $\mathbb{Z}_\ell$, the image of $\wedge^2 M_{f^\Sigma,\lambda}$, which is $\eta^\Sigma_{f,\lambda}$, ...; equivalently the Gram determinant of the pairing on $M_{f^\Sigma,\lambda}$ is $(\eta^\Sigma_{f,\lambda})^2$ up to a unit". This is Proposition 3.87(ii), as $\hat{\delta}_!$ is alternating. The same proposition is behind "the Gram determinant of a rank-two alternating form is the square of its ideal of values" in the proof of Proposition prop:pullback, and behind $d = 2$, $\Delta = (\eta^\emptyset_{f,\lambda})^2$ when Lemma lem:ddt417 is applied in Step 2 of the proof of Theorem thm:quant.

Proposition 3.89 (adjoints)**.** *Let $\langle\ ,\ \rangle$ be a perfect pairing on a lattice L, with Gram matrix G in a basis, coordinates written as columns so that $\langle x, y\rangle = x^{\mathsf{T}} G y$.*

(i) Every $A \in \mathrm{End}_R(L)$ has a unique adjoint *$A^\dagger$ with $\langle Ax, y\rangle = \langle x, A^\dagger y\rangle$; in matrices $A^\dagger = G^{-1} A^{\mathsf{T}} G$. Moreover $(AB)^\dagger = B^\dagger A^\dagger$, and $(A^\dagger)^\dagger = A$ if the pairing is symmetric or antisymmetric.*

(ii) Let $\mathbb{T} \subseteq \mathrm{End}_R(L)$ be a commutative subring of self-adjoint endomorphisms. For every ideal $\mathfrak{a} \subseteq \mathbb{T}$, $(\mathfrak{a}L)^\perp = L[\mathfrak{a}]$.

(iii) In (ii), every idempotent e of $\mathbb{T}$, or of $\mathbb{T} \otimes_R S$ acting on $L \otimes_R S$ for an R-algebra S that is a principal ideal domain, is self-adjoint; $L = eL \oplus (1-e)L$ is an orthogonal decomposition (on both sides), and the restriction of the pairing to eL is perfect.

(iv) (Twisted pairings.) Let $w \in \mathrm{Aut}_R(L)$ satisfy $A^\dagger = wAw^{-1}$ for all $A \in \mathbb{T}$, and put $[x, y] = \langle x, wy\rangle$. Then $[\ ,\ ]$ is perfect and every $A \in \mathbb{T}$ is self-adjoint for it. If $\langle\ ,\ \rangle$ is antisymmetric and $w^\dagger = w$ (for instance if w is an involution preserving the pairing, so that $w^\dagger = w^{-1} = w$), then $[\ ,\ ]$ is antisymmetric, hence alternating when 2 is a nonzerodivisor.

Proof. (i) For fixed y, $x \mapsto \langle Ax, y\rangle$ is in $L^\vee$, so equals $\langle -, z\rangle$ for a unique z (β is bijective); put $A^\dagger y = z$. In matrices $x^{\mathsf{T}} A^{\mathsf{T}} G y = x^{\mathsf{T}} G A^\dagger y$ for all x, y, so $GA^\dagger = A^{\mathsf{T}} G$. Then $\langle ABx, y\rangle = \langle Bx, A^\dagger y\rangle = \langle x, B^\dagger A^\dagger y\rangle$. If $\langle x, y\rangle = \pm\langle y, x\rangle$, then $\langle A^\dagger x, y\rangle = \pm\langle y, A^\dagger x\rangle = \pm\langle Ay, x\rangle = \langle x, Ay\rangle$. (ii) $y \in (\mathfrak{a}L)^\perp$ iff $\langle ax, y\rangle = \langle x, ay\rangle = 0$ for all $a \in \mathfrak{a}$ and $x \in L$, iff $ay = 0$ for all $a \in \mathfrak{a}$ (perfectness). (iii) Elements of $\mathbb{T}$ are self-adjoint by hypothesis, and self-adjointness is preserved by S-linear combinations, so every element of $\mathbb{T} \otimes S$ is self-adjoint for the extended pairing (which is perfect, Proposition 3.82(iii)). For $x \in eL$ and $y \in (1-e)L$, $\langle x, y\rangle = \langle ex, y\rangle = \langle x, ey\rangle = 0$ since $ey = e(1-e)y = 0$; likewise $\langle y, x\rangle = 0$. The summands are free (direct summands of a lattice over a principal ideal domain), and in a basis adapted to the decomposition the Gram matrix is block diagonal, with unit determinant equal to the product of the two block determinants; so

each block determinant is a unit. (iv) $x \mapsto [x,-]$ is the composite of α with the isomorphism induced by w, so $[\ ,\ ]$ is perfect. For $A \in \mathbb{T}$, $[Ax,y] = \langle x, A^\dagger wy\rangle = \langle x, wAw^{-1}wy\rangle = [x,Ay]$. If $\langle\ ,\ \rangle$ is antisymmetric and $w^\dagger = w$, then $[y,x] = \langle y,wx\rangle = -\langle wx,y\rangle = -\langle x,w^\dagger y\rangle = -[x,y]$. An involution preserving the pairing satisfies $\langle wx,y\rangle = \langle w^2x,wy\rangle = \langle x,wy\rangle$. □

Why part (iv) is needed is already visible in rank two. Take the alternating pairing $\langle x,y\rangle = x_1y_2 - x_2y_1$, whose Gram matrix is the matrix $J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ of the paper. For $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ the formula of (i) gives

$$A^\dagger = J^{-1}A^{\mathsf{T}}J = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} = \operatorname{adj}(A),$$

the adjugate (checked with PARI). So A is self-adjoint iff $a = d$ and $2b = 2c = 0$, that is, over a ring in which 2 is a nonzerodivisor, iff A is a scalar. An alternating pairing therefore makes almost no operator self-adjoint; instead it satisfies $A^\dagger = \det(A)A^{-1}$ for invertible A. This is the situation of the cup product on $H^1(X_0(N))$, for which the adjoint of T_n is not T_n but wT_nw^{-1}; twisting by the Atkin-Lehner involution w, as in (iv), restores self-adjointness, and the twisted pairing is still alternating because $w^\dagger = w$.

In the paper 3.90. Section 4.1: the cup product on $H^1(X_0(M^\Sigma),\mathbb{Z}_\ell)$ is perfect and alternating, the Atkin-Lehner involution $w = w_{M^\Sigma}$ preserves it, and wT_nw^{-1} is the adjoint of T_n for the cup product (Chapters 8 and 14). By Proposition 3.89(iv) the pairing $\hat\delta_!$, which is $\frac12\langle x,wy\rangle$ on classes from $X_0(M^\Sigma)$, is perfect (the factor $\frac12$ being a unit as ℓ is odd), alternating (antisymmetric over the domain $\mathbb{Z}_\ell$ of characteristic 0, Proposition 3.87) and makes every Hecke operator, U_p included, self-adjoint: "this is what the composition with w is for". In the paragraph after Lemma lem:hecke (and in Step 2 of the proof of Theorem thm:quant) the paper uses Proposition 3.89(iii): "the idempotent $e_{\mathfrak{m}}$ is self-adjoint for $\hat\delta_!$, so $H^1(X_0(N),\mathbb{Z}_\ell)$ splits orthogonally into its local components and the pairing is perfect on each". The idempotent $e_{\mathfrak{m}}$ lies in $\mathbb{T}\otimes\mathbb{Z}_\ell$, not in $\mathbb{T}$, which is why (iii) allows $\mathbb{T}\otimes S$.

Proposition 3.91 (an algebra paired with a module)**.** *Let $\mathbb{T}$ be a commutative R-algebra that is free of finite rank as an R-module, S a $\mathbb{T}$-module free of finite rank over R, and $\langle\ ,\ \rangle\colon S\times\mathbb{T}\to R$ a perfect R-bilinear pairing with $\langle ts,u\rangle = \langle s,tu\rangle$ for $s\in S$ and $t,u\in\mathbb{T}$.*

(i) $s\mapsto\langle s,-\rangle$ is an isomorphism of $\mathbb{T}$-modules $S\simeq\mathbb{T}^\vee = \operatorname{Hom}_R(\mathbb{T},R)$, where $(t\varphi)(u) = \varphi(tu)$.

(ii) For every ideal $\mathfrak{a}\subseteq\mathbb{T}$, $S[\mathfrak{a}]$ corresponds to $\operatorname{Hom}_R(\mathbb{T}/\mathfrak{a},R)$, the functionals vanishing on $\mathfrak{a}$; it is saturated in S, of rank $\operatorname{rank}_R(\mathbb{T}/\mathfrak{a})$.

(iii) Let $\mathfrak{a},\mathfrak{b}\subseteq\mathbb{T}$ be ideals with $\mathfrak{a}\cap\mathfrak{b} = 0$, $\mathbb{T}/\mathfrak{a}$ and $\mathbb{T}/\mathfrak{b}$ torsion-free, and $\operatorname{rank}\mathbb{T}/\mathfrak{a} + \operatorname{rank}\mathbb{T}/\mathfrak{b} = \operatorname{rank}\mathbb{T}$. Then $\mathbb{T}\hookrightarrow\mathbb{T}/\mathfrak{a}\times\mathbb{T}/\mathfrak{b}$ has torsion cokernel $\mathbb{T}/(\mathfrak{a}+\mathfrak{b})$ (Proposition 3.13), $S[\mathfrak{a}]\oplus S[\mathfrak{b}]\subseteq S$, and $S/(S[\mathfrak{a}]\oplus S[\mathfrak{b}])\simeq\operatorname{Hom}_R(\mathbb{T}/(\mathfrak{a}+\mathfrak{b}),K/R)$; for $R=\mathbb{Z}$ or $\mathbb{Z}_\ell$ this is $(\mathbb{T}/(\mathfrak{a}+\mathfrak{b}))^*$, of the same order as $\mathbb{T}/(\mathfrak{a}+\mathfrak{b})$.

(iv) $\mathbb{T}$ acts faithfully on S.

Proof. (i) It is an R-isomorphism because the pairing is perfect, and $\mathbb{T}$-linear: $\langle ts,u\rangle = \langle s,tu\rangle = (t\langle s,-\rangle)(u)$. (ii) $s\in S[\mathfrak{a}]$ iff $\langle as,u\rangle = \langle s,au\rangle = 0$ for all $a\in\mathfrak{a}$, $u\in\mathbb{T}$, iff $\langle s,-\rangle$ vanishes on the ideal $\mathfrak{a}$. Such functionals are $\operatorname{Hom}_R(\mathbb{T}/\mathfrak{a},R) = \operatorname{Hom}_R((\mathbb{T}/\mathfrak{a})/(\mathbb{T}/\mathfrak{a})_{\mathrm{tor}},R)$, of rank $\operatorname{rank}(\mathbb{T}/\mathfrak{a})$; saturation is Proposition 3.49(iii). (iii) The cokernel of $\mathbb{T}\to\mathbb{T}/\mathfrak{a}\times\mathbb{T}/\mathfrak{b}$ is $\mathbb{T}/(\mathfrak{a}+\mathfrak{b})$, and the

two lattices have the same rank by hypothesis, so it is torsion. Apply Proposition 3.51 to this injection of lattices: $(\mathbb{T}/\mathfrak{a}\times\mathbb{T}/\mathfrak{b})^\vee\hookrightarrow\mathbb{T}^\vee$, with cokernel $\mathrm{Hom}(\mathbb{T}/(\mathfrak{a}+\mathfrak{b}),K/R)$. Under (i) and (ii) the image of $(\mathbb{T}/\mathfrak{a})^\vee\oplus(\mathbb{T}/\mathfrak{b})^\vee$ in $\mathbb{T}^\vee$ is $S[\mathfrak{a}]+S[\mathfrak{b}]$; this sum is direct because the source is a direct sum and the map is injective. (iv) If $tS=0$ then $\langle s,tu\rangle=\langle ts,u\rangle=0$ for all s,u, so $tu=0$ for all u (perfectness); with $u=1$, $t=0$. □

In the paper 3.92. In Lemma lem:crit, $R=\mathbb{Z}$, $\mathbb{T}$ is the Hecke algebra, $S=S_2(\Gamma_0(N);\mathbb{Z})$ and $\langle g,t\rangle=a_1(tg)$ is perfect (Chapter 13); it satisfies $\langle tg,u\rangle=a_1(utg)=\langle g,tu\rangle$. Take $\mathfrak{a}=\ker\phi_f$ and $\mathfrak{b}=\mathrm{Ann}_{\mathbb{T}}(\mathfrak{a})$, the paper's I and J (the paper defines $J=\mathrm{Ann}_{\mathbb{T}}(f^\perp)$; it equals $\mathrm{Ann}_{\mathbb{T}}(I)$ because $\mathbb{T}\otimes\mathbb{Q}=\mathbb{Q}\times\mathbb{T}'$ with $\mathbb{T}'$ acting faithfully on $f^\perp$). Then $S[\mathfrak{a}]=\mathbb{Z}f$ (f is the primitive form killed by $\mathfrak{a}$), and $S[\mathfrak{b}]=L$ is the orthogonal complement lattice. By Proposition 3.110(iii), $\mathfrak{a}=\mathbb{T}\cap(0\times\mathbb{T}')$ and $\mathfrak{b}=\mathbb{T}\cap(\mathbb{Q}\times0)$, so $\mathbb{T}/\mathfrak{a}$ and $\mathbb{T}/\mathfrak{b}$ are torsion-free (Proposition 3.49(iii)), and $\mathfrak{b}$ is a lattice in $\mathbb{Q}\times0$, so $\operatorname{rank}\mathbb{T}/\mathfrak{b}=\operatorname{rank}\mathbb{T}-1$ and the ranks are complementary. So the paper's dualising step (Paper link 3.54) is Proposition 3.91(iii). The paper leaves these hypotheses implicit; its assertion that $\mathbb{T}/(I+J)\simeq\mathbb{Z}/\phi_f(J)$ is cyclic *of order* r' presupposes them: as $I\cap J=0$, the quotient is finite iff $\phi_f(J)\neq0$, iff $J\neq0$, which is the rank condition.

3.10 Finite free algebras over a discrete valuation ring; idempotents; generalised eigenspaces

The Hecke algebra $\mathbb{T}$ is a commutative ring that is free of finite rank over $\mathbb{Z}$. The paper uses three of its structural features. After tensoring with $\mathbb{Q}$ it is a product of local Artinian algebras, one of which is $\mathbb{Q}$, the factor of f ("$\mathbb{T}\otimes\mathbb{Q}=\mathbb{Q}\times\mathbb{T}'$", Lemma lem:crit). After tensoring with $\mathbb{Z}_\ell$ it is a product of local rings $\mathbb{T}_\mathfrak{m}$ cut out by idempotents (Lemma lem:hecke, Remark rem:free, Theorem thm:quant). And its action on forms decomposes into generalised eigenspaces, on which the operators need not be semisimple (Lemma lem:old, Theorem thm:twist, Lemma lem:step1). In the language of linear algebra this section is the Jordan decomposition of a commuting family of matrices, done over $\mathbb{Z}$ and $\mathbb{Z}_\ell$ rather than over $\mathbb{C}$.

Theorem 3.93 (finite-dimensional commutative algebras)**.** *Let A be a commutative algebra of finite dimension over a field F.*

(i) Every prime ideal of A is maximal; A has finitely many maximal ideals $\mathfrak{m}_1,\dots,\mathfrak{m}_s$, with $s\le\dim_F A$; and the Jacobson radical $\mathfrak{J}=\bigcap_i\mathfrak{m}_i$ is nilpotent.

(ii) $A\simeq\prod_{i=1}^s A_{\mathfrak{m}_i}$, each factor a local ring with nilpotent maximal ideal; the factors are cut out by idempotents $e_1,\dots,e_s$ with $\sum e_i=1$ and $e_ie_j=0$ for $i\neq j$, and $A_{\mathfrak{m}_i}\simeq e_iA\simeq A/\mathfrak{m}_i^N$ for N large.

(iii) A is reduced (has no nonzero nilpotents) iff $\mathfrak{J}=0$ iff A is a product of fields.

(iv) Every A-module V is $\bigoplus_i e_iV$, and $e_iV=V_{\mathfrak{m}_i}$.

Proof. (i) If P is prime, A/P is a finite-dimensional domain, hence a field (multiplication by $a\neq0$ is an injective, hence surjective, linear map). If $\mathfrak{m}_1,\dots,\mathfrak{m}_s$ are distinct maximal ideals, they are pairwise comaximal and $A\to\prod A/\mathfrak{m}_i$ is surjective by the Chinese remainder theorem (Chapter 2), so $s\le\dim A$. The powers $\mathfrak{J}^k$ form a decreasing chain of subspaces, so $\mathfrak{J}^N=\mathfrak{J}^{N+1}=\mathfrak{J}\cdot\mathfrak{J}^N$ for some N; by Theorem 3.35(i) (for an ideal in the Jacobson radical), $\mathfrak{J}^N=0$: its hypotheses hold because $\mathfrak{J}^N$ is a finite-dimensional F-space, hence a finitely generated A-module, and $\mathfrak{J}\cdot\mathfrak{J}^N=\mathfrak{J}^N$

with $\mathfrak{J} = \mathfrak{J}(A)$. (ii) The ideals $\mathfrak{m}_i^N$ are pairwise comaximal (if $\mathfrak{m}_i^N + \mathfrak{m}_j^N$ were proper it would lie in a maximal ideal containing both $\mathfrak{m}_i$ and $\mathfrak{m}_j$), and $\prod_i \mathfrak{m}_i^N \subseteq \mathfrak{J}^N = 0$. By the Chinese remainder theorem $A \simeq \prod_i A/\mathfrak{m}_i^N$. The maximal ideals of $A/\mathfrak{m}_i^N$ correspond to maximal ideals containing $\mathfrak{m}_i^N$, hence $\mathfrak{m}_i$; so $A/\mathfrak{m}_i^N$ is local with maximal ideal $\mathfrak{m}_i/\mathfrak{m}_i^N$, nilpotent. The idempotents are the unit vectors of the product, and localisation at $\mathfrak{m}_i$ picks out the i-th factor (Theorem 3.38(vii)). (iii) If A is reduced, the nilpotent $\mathfrak{J}$ is 0, and $A \simeq \prod A/\mathfrak{m}_i$ by (ii) with $N = 1$. A product of fields is reduced. (iv) $v = \sum e_i v$, and $e_i V \cap \sum_{j\neq i} e_j V = 0$ by applying e_i. In $A_{\mathfrak{m}_i}$, e_i becomes a unit ($e_i \notin \mathfrak{m}_i$) and $e_j = 0$ for $j \neq i$ (as $e_i e_j = 0$); so $(e_j V)_{\mathfrak{m}_i} = 0$, while elements outside $\mathfrak{m}_i$ act invertibly on $e_i V$, a module over the local ring $e_i A$; hence $V_{\mathfrak{m}_i} = e_i V$. □

A small example: $A = \mathbb{Q}[x]/(x^2(x-1))$ has the two maximal ideals (x) and $(x-1)$. In A one has $x^3 = x^2$, so x^2 is idempotent ($x^4 = x{\cdot}x^3 = x^3 = x^2$), and $A = x^2A \times (1-x^2)A \simeq \mathbb{Q}\times\mathbb{Q}[x]/(x^2)$: on the first factor x acts as 1, on the second it is nilpotent. So A is not reduced, $\mathfrak{J} = (x(x-1))$ with $\mathfrak{J}^2 = 0$ (as $x^2(x-1)^2 = x^2(x-1)\cdot(x-1) = 0$), and the idempotent x^2 is a polynomial in x found by the Chinese remainder theorem: it is $\equiv 0 \pmod{x^2}$ and $\equiv 1 \pmod{x-1}$. The integral version of this algebra is Example 3.112(e).

Theorem 3.94 (finite free algebras over a discrete valuation ring)**.** *Let $\mathbb{T}$ be a commutative $\mathcal{O}$-algebra that is finite and free as an $\mathcal{O}$-module (a* finite free $\mathcal{O}$*-algebra).*

(i) $\mathbb{T}$ is Noetherian. Every maximal ideal $\mathfrak{M}$ of $\mathbb{T}$ contains ϖ, so the maximal ideals of $\mathbb{T}$ correspond to those of the finite k-algebra $\mathbb{T}/\varpi\mathbb{T}$; they are finite in number, and their residue fields are finite extensions of k.

(ii) $\mathbb{T}$ is torsion-free and $\mathbb{T} \subseteq \mathbb{T}_K := \mathbb{T} \otimes_{\mathcal{O}} K$, a finite-dimensional K-algebra. $\mathbb{T}$ is reduced iff $\mathbb{T}_K$ is, iff $\mathbb{T}$ embeds in a product of fields.

(iii) Let $\pi\colon \mathbb{T} \to \mathcal{O}$ be a surjective homomorphism of $\mathcal{O}$-algebras, with kernel $\wp$. Then $\wp$ is a prime ideal, $\mathbb{T} = \mathcal{O}\cdot 1 \oplus \wp$ as $\mathcal{O}$-modules, and $\mathfrak{m}_\pi = \pi^{-1}(\varpi\mathcal{O}) = \wp + \varpi\mathbb{T}$ is a maximal ideal with residue field k. The extension $\pi_K\colon \mathbb{T}_K \to K$ is a surjective homomorphism; it factors through exactly one of the local factors of $\mathbb{T}_K$ (Theorem 3.93).

Proof. (i) $\mathbb{T}$ is a finitely generated module over the Noetherian $\mathcal{O}$ (Proposition 3.31). Let $\mathfrak{M}$ be maximal; $\mathbb{T}/\mathfrak{M}$ is a field which is a finitely generated module over the image $D = \mathcal{O}/(\mathfrak{M}\cap\mathcal{O})$ of $\mathcal{O}$, a domain. Then D is a field: for $0 \neq x \in D$, the element $y = x^{-1} \in \mathbb{T}/\mathfrak{M}$ satisfies a monic equation $y^n + d_1 y^{n-1} + \cdots + d_n = 0$ over D (Lemma 3.32 with $\mathfrak{a} = D$, applied to multiplication by y), and multiplying by x^{n-1} gives $y = -(d_1 + d_2 x + \cdots + d_n x^{n-1}) \in D$. So $\mathfrak{M}\cap\mathcal{O}$ is maximal, that is, $\varpi\mathcal{O}$, and $\varpi \in \mathfrak{M}$. The rest follows from Theorem 3.8(iii) and Theorem 3.93(i), as $\mathbb{T}/\mathfrak{M}$ is a quotient of the finite-dimensional k-algebra $\mathbb{T}/\varpi\mathbb{T}$. (ii) Free modules are torsion-free and embed in their tensor product with K (Proposition 3.46(i)). If $x \in \mathbb{T}_K$ is nilpotent, so is $\varpi^k x \in \mathbb{T}$ for k large; so $\mathbb{T}$ is reduced iff $\mathbb{T}_K$ is, and then $\mathbb{T} \subseteq \mathbb{T}_K$, a product of fields (Theorem 3.93(iii)). Conversely a subring of a product of fields is reduced. (iii) $\mathbb{T}/\wp \simeq \mathcal{O}$ is a domain. $t = \pi(t)\cdot 1 + (t - \pi(t)\cdot 1)$ with $t - \pi(t)\cdot 1 \in \wp$, and $\mathcal{O}\cdot 1 \cap \wp = 0$ because $\pi(a\cdot 1) = a$. If $\pi(t) = \varpi a$ then $t = \varpi a \cdot 1 + (t - \pi(t)\cdot 1) \in \varpi\mathbb{T} + \wp$; the reverse inclusion is clear, and $\mathbb{T}/\mathfrak{m}_\pi \simeq \mathcal{O}/\varpi = k$. The kernel of π_K is a maximal ideal of $\mathbb{T}_K = \prod_i A_i$, hence of the form $A_1 \times \cdots \times \mathfrak{m}_{A_i} \times \cdots \times A_s$ for one i (Chapter 2: ideals of a product); so $\pi_K(e_j) = 0$ for $j \neq i$ and $\pi_K(e_i) = 1$. □

Theorem 3.95 (idempotent lifting and the decomposition $\mathbb{T} = \prod \mathbb{T}_{\mathfrak{m}}$)**.** *Let $\mathcal{O}$ be a* complete *discrete valuation ring (for example $\mathbb{Z}_\ell$, or $\mathcal{O}_\lambda$ of Chapter 7), and $\mathbb{T}$ a finite free $\mathcal{O}$-algebra.*

(i) Every idempotent $\bar{e}$ of $\mathbb{T}/\varpi\mathbb{T}$ lifts to a unique idempotent of $\mathbb{T}$.

(ii) $\mathbb{T} \simeq \prod_{\mathfrak{m}} \mathbb{T}_{\mathfrak{m}}$, the product over the maximal ideals of $\mathbb{T}$, where $\mathbb{T}_{\mathfrak{m}} = e_{\mathfrak{m}}\mathbb{T}$ for an idempotent $e_{\mathfrak{m}}$, and $\mathbb{T}_{\mathfrak{m}}$ is the localisation of $\mathbb{T}$ at $\mathfrak{m}$; each $\mathbb{T}_{\mathfrak{m}}$ is a local ring and a finite free $\mathcal{O}$-algebra. Moreover $e_{\mathfrak{m}} \notin \mathfrak{m}$ and $e_{\mathfrak{m}'} \in \mathfrak{m}$ for $\mathfrak{m}' \neq \mathfrak{m}$.

(iii) For every $\mathbb{T}$-module L, $L = \bigoplus_{\mathfrak{m}} e_{\mathfrak{m}}L$ and $L_{\mathfrak{m}} = e_{\mathfrak{m}}L$; if L is finitely generated and free over $\mathcal{O}$, so is each $L_{\mathfrak{m}}$.

(iv) A ring homomorphism ϕ from $\mathbb{T}$ to a local ring factors through exactly one $\mathbb{T}_{\mathfrak{m}}$. For $\pi\colon \mathbb{T} \to \mathcal{O}$ as in Theorem 3.94(iii): $\pi(e_{\mathfrak{m}_\pi}) = 1$ and $\pi(e_{\mathfrak{m}'}) = 0$ for $\mathfrak{m}' \neq \mathfrak{m}_\pi$.

(v) Completeness is necessary: $\mathbb{Z}_{(11)}[x]/(x^2 + x - 1)$ is a finite free $\mathbb{Z}_{(11)}$-algebra with two maximal ideals, $(11, x - 3)$ and $(11, x - 7)$, but no idempotent other than 0 and 1.

Proof. (i) *Existence.* Let $e_0 \in \mathbb{T}$ lift $\bar{e}$, and define $e_{j+1} = 3e_j^2 - 2e_j^3$. Put $d_j = e_j^2 - e_j$. A direct computation gives

$$e_{j+1} - e_j = (1 - 2e_j)d_j, \qquad e_{j+1}^2 - e_{j+1} = d_j^2\,(4d_j - 3).$$

(Expand both sides as polynomials in $e = e_j$, with $d = e^2 - e$: the first is $3e^2 - 2e^3 - e$ on both sides, and the second is $4e^6 - 12e^5 + 9e^4 + 2e^3 - 3e^2$ on both sides; both identities were also checked with PARI.) The iteration is Newton's method for the equation $e^2 - e = 0$: the Newton step is $e - (2e - 1)^{-1}d$, and since $(2e - 1)^2 = 4d + 1$, the inverse $(2e - 1)^{-1}$ is congruent to $2e - 1$ modulo d; replacing it by $2e - 1$ gives $e - (2e - 1)d = 3e^2 - 2e^3$, and keeps the quadratic convergence. Since $d_0 \in \varpi\mathbb{T}$, induction gives $d_j \in \varpi^{2^j}\mathbb{T}$, and $e_{j+1} - e_j \in \varpi^{2^j}\mathbb{T}$. As $\mathbb{T} \simeq \mathcal{O}^n$ is complete (Theorem 3.58(vi) holds verbatim over any complete $\mathcal{O}$), the e_j converge to some e, with $e \equiv e_0 \pmod{\varpi}$ and $e^2 - e = \lim d_j = 0$. (Here $d_j \in \varpi^{2^j}\mathbb{T}$ follows from $d_{j+1} = d_j^2(4d_j - 3)$ by induction, starting from $d_0 \in \varpi\mathbb{T}$ because $\bar{e}$ is idempotent.) *Uniqueness.* If e, e' are idempotents with $e \equiv e' \pmod{\varpi}$, then $x = e - e'$ satisfies $x^3 = x$ (expand, using $e^2 = e$, $e'^2 = e'$ and commutativity: $x^2 = e - 2ee' + e'$ and $x^3 = e - e'$). So $x = x^3 = x^9 = \cdots \in \bigcap_k \varpi^k\mathbb{T} = 0$: since $x \in \varpi\mathbb{T}$, the power x^{3^k} lies in $\varpi^{3^k}\mathbb{T}$, and $\bigcap_k \varpi^k\mathbb{T} = 0$ because $\mathbb{T}$ is free over $\mathcal{O}$ and $\bigcap_k \varpi^k\mathcal{O} = 0$. (ii) By Theorem 3.93, $\mathbb{T}/\varpi\mathbb{T} = \prod_{\bar{\mathfrak{m}}} A_{\bar{\mathfrak{m}}}$ with orthogonal idempotents $\bar{e}_{\mathfrak{m}}$ summing to 1; the $\bar{\mathfrak{m}}$ correspond to the maximal ideals $\mathfrak{m}$ of $\mathbb{T}$ (Theorem 3.94(i)). Lift them to idempotents $e_{\mathfrak{m}}$. For $\mathfrak{m} \neq \mathfrak{m}'$, $e_{\mathfrak{m}}e_{\mathfrak{m}'}$ is an idempotent lifting 0, hence 0; and $\sum e_{\mathfrak{m}}$ is an idempotent lifting 1, hence 1. So $\mathbb{T} = \prod e_{\mathfrak{m}}\mathbb{T}$. Each $e_{\mathfrak{m}}\mathbb{T}$ is a direct summand of $\mathbb{T}$, so finite free over $\mathcal{O}$ (Theorem 3.40), and a finite free $\mathcal{O}$-algebra with identity $e_{\mathfrak{m}}$; its maximal ideals contain ϖ and correspond to those of $e_{\mathfrak{m}}\mathbb{T}/\varpi e_{\mathfrak{m}}\mathbb{T} = A_{\bar{\mathfrak{m}}}$, which is local. So $e_{\mathfrak{m}}\mathbb{T}$ is local, and the maximal ideal of $\mathbb{T}$ corresponding to it is the product of its maximal ideal with the other factors, which is $\mathfrak{m}$; it contains $e_{\mathfrak{m}'}$ for $\mathfrak{m}' \neq \mathfrak{m}$ and not $e_{\mathfrak{m}}$. Localisation at $\mathfrak{m}$ picks out the factor $e_{\mathfrak{m}}\mathbb{T}$ (Theorem 3.38(vii)). (iii) As in Theorem 3.93(iv). The summands of a free $\mathcal{O}$-module of finite rank are free. (iv) The image of an idempotent in a local ring is 0 or 1 ($e(1-e) = 0$ and one of e, $1-e$ is a unit). The images of the $e_{\mathfrak{m}}$ are orthogonal and sum to 1, so exactly one is 1 and ϕ factors through that factor. For π, reduce modulo ϖ: $\bar{\pi}\colon \mathbb{T} \to k$ has kernel $\mathfrak{m}_\pi$, which contains $e_{\mathfrak{m}'}$ for $\mathfrak{m}' \neq \mathfrak{m}_\pi$ and not $e_{\mathfrak{m}_\pi}$, by (ii). (v) The ring is a subring of $\mathbb{Q}(\sqrt{5})$, a domain (the polynomial is irreducible over $\mathbb{Q}$, having discriminant 5), so $e(1 - e) = 0$ forces $e \in \{0, 1\}$. It is free with basis $1, x$ over $\mathbb{Z}_{(11)}$, so its maximal ideals contain 11 (Theorem 3.94(i)) and correspond to those of $\mathbb{F}_{11}[x]/((x - 3)(x - 7)) \simeq \mathbb{F}_{11} \times \mathbb{F}_{11}$, since $x^2 + x - 1 \equiv (x - 3)(x - 7) \pmod{11}$. □

Corollary 3.96 (Hecke-type algebras)**.** *Let $\mathbb{T}$ be a commutative ring that is free of finite rank as a $\mathbb{Z}$-module. Then $\mathbb{T}\otimes\mathbb{Z}_\ell$ is a finite free $\mathbb{Z}_\ell$-algebra; its maximal ideals correspond to the maximal ideals $\mathfrak{m}$ of $\mathbb{T}$ containing ℓ (as $\mathfrak{m}\otimes\mathbb{Z}_\ell$); and $\mathbb{T}\otimes\mathbb{Z}_\ell=\prod_{\mathfrak{m}\ni\ell}\mathbb{T}_\mathfrak{m}$ with $\mathbb{T}_\mathfrak{m}=(\mathbb{T}\otimes\mathbb{Z}_\ell)_\mathfrak{m}$, the convention of Convention 3.2.*

Proof. $\mathbb{T}\otimes\mathbb{Z}_\ell\simeq\mathbb{Z}_\ell^n$. Its maximal ideals correspond to those of $(\mathbb{T}\otimes\mathbb{Z}_\ell)/\ell=\mathbb{T}/\ell\mathbb{T}$ (Theorem 3.94(i) and Theorem 3.58(iii)), which are the maximal ideals of $\mathbb{T}$ containing ℓ. Apply Theorem 3.95. □

Remark 3.97. One can show that $\mathbb{T}_\mathfrak{m}$ is also the $\mathfrak{m}$-adic completion $\varprojlim\mathbb{T}/\mathfrak{m}^k$ of $\mathbb{T}$; we do not use this, and do not prove it (see [62, Chapter 7]).

Example 3.98 (the Hecke algebra of level 23)**.** Let $\mathbb{T}=\mathbb{Z}[x]/(x^2+x-1)=\mathbb{Z}[\frac{1+\sqrt{5}}{2}]$. This is the Hecke algebra of $S_2(\Gamma_0(23))$, with $x=T_2$ (Chapter 6): the newforms of level 23 have $a_2=(-1\pm\sqrt{5})/2$, the roots of x^2+x-1 (PARI: `charpoly(mfheckemat(mfinit([23,2],1),2))`); $\mathbb{T}_{23}\otimes\mathbb{Q}$ has dimension $\dim S_2(\Gamma_0(23))=2$ (Proposition 3.91(i)), so it is $\mathbb{Q}(\sqrt{5})$; and $\mathbb{Z}[T_2]\subseteq\mathbb{T}_{23}$ is an order of discriminant 5, squarefree, hence the maximal order, so $\mathbb{T}_{23}=\mathbb{Z}[T_2]$.

- $\ell=11$: $x^2+x-1\equiv(x-3)(x-7)\pmod{11}$, so $\mathbb{T}\otimes\mathbb{Z}_{11}\simeq\mathbb{Z}_{11}\times\mathbb{Z}_{11}$, by $x\mapsto(r_1,r_2)$ with $r_1\equiv7$, $r_2\equiv3$ the roots in $\mathbb{Z}_{11}$. Modulo $11^6=1771561$ they are $r_1=728020$ and $r_2=1043540$ (PARI's `polrootspadic`; $r_1+r_2=11^6-1\equiv-1$). The idempotent of the first factor is $e=(x-r_2)/(r_1-r_2)$, which is $\equiv784x+1058\pmod{11^3}$ and $\equiv1708457x+854229\pmod{11^6}$; it is also the limit of the iteration $e\mapsto3e^2-2e^3$ started at $(x-3)/4$ (five steps give it modulo 11^6).
- $\ell=5$: $x^2+x-1\equiv(x-2)^2\pmod5$, so $\mathbb{T}\otimes\mathbb{Z}_5$ is local; it is the ring of integers of $\mathbb{Q}_5(\sqrt{5})$, a ramified discrete valuation ring.
- $\ell=2,3$: x^2+x-1 is irreducible modulo 2 and modulo 3, so $\mathbb{T}\otimes\mathbb{Z}_2$ and $\mathbb{T}\otimes\mathbb{Z}_3$ are local, unramified discrete valuation rings with residue fields $\mathbb{F}_4$ and $\mathbb{F}_9$.

A second example: $\mathbb{T}=\mathbb{Z}[x]/(x^2-4)\simeq\{(a,b)\in\mathbb{Z}^2:a\equiv b\pmod4\}$ (by $x\mapsto(2,-2)$). Then $\mathbb{T}\otimes\mathbb{Z}_3\simeq\mathbb{Z}_3\times\mathbb{Z}_3$ with idempotent $(x+2)/4$, while $\mathbb{T}\otimes\mathbb{Z}_2$ is local ($x^2-4\equiv x^2\pmod2$) and not a domain ($(x-2)(x+2)=0$).

```
polrootspadic(x^2+x-1, 11, 6)      \\ roots = 3 + ... and 7 + ... in Z_11
e = Mod(Mod(1,11^6)*(x-3)/4, x^2+x-1);
for(i=1,5, e = 3*e^2 - 2*e^3); e   \\ Mod(1708457*x + 854229, x^2+x-1)
factormod(x^2+x-1, 5)              \\ (x+3)^2, that is (x-2)^2
```

In the paper 3.99. In the paragraph after Lemma lem:hecke, $\mathfrak{m}$ is "the maximal ideal of $\mathbb{T}\otimes\mathbb{Z}_\ell$ containing ℓ and $\ker\phi_f$"; it is $\mathfrak{m}_{\phi_f}$ of Theorem 3.94(iii), for $\phi_f\otimes\mathbb{Z}_\ell\colon\mathbb{T}\otimes\mathbb{Z}_\ell\to\mathbb{Z}_\ell$. By Theorem 3.95(iv), ϕ_f factors through $\mathbb{T}_\mathfrak{m}$ and kills the other local factors; in the proof of Lemma lem:step1, "The idempotent $e_\mathfrak{m}$ of $\mathbb{T}_\ell$ fixes g^S (as π factors through $\mathbb{T}_\mathfrak{m}$)" uses the idempotent $e_\mathfrak{m}$ of (ii). Remark rem:free is about $H^1(X_0(N),\mathbb{Z}_\ell)_\mathfrak{m}=e_\mathfrak{m}H^1(X_0(N),\mathbb{Z}_\ell)$, a free $\mathbb{Z}_\ell$-module by (iii).

Theorem 3.100 (generalised eigenspaces)**.** *(i) Let V be a nonzero finite-dimensional vector space over a field F and $\mathbb{T}\subseteq\mathrm{End}_F(V)$ a commutative subalgebra such that the characteristic polynomial of every $t\in\mathbb{T}$ splits into linear factors over F. For an F-algebra homomorphism $\phi\colon\mathbb{T}\to F$ (a* system of eigenvalues*) put*

$$V(\phi)=\{v\in V:(t-\phi(t))^{\dim V}v=0\text{ for all }t\in\mathbb{T}\}.$$

Then $V = \bigoplus_\phi V(\phi)$, the sum over all systems of eigenvalues, and each $V(\phi) \neq 0$. The projection onto $V(\phi)$ is an idempotent $e_\phi \in \mathbb{T}$, the idempotent of the local factor of $\mathbb{T}$ at $\ker\phi$ (Theorem 3.93). Each $V(\phi)$ contains a common eigenvector $v \neq 0$, with $tv = \phi(t)v$ for all $t \in \mathbb{T}$. Every $\mathbb{T}$-stable subspace W satisfies $W = \bigoplus_\phi (W \cap V(\phi))$.

(ii) (Integral version.) Let $\mathcal{O}$ be a complete discrete valuation ring, L a lattice, and $\mathbb{T} \subseteq \mathrm{End}_{\mathcal{O}}(L)$ a commutative subalgebra, such that the characteristic polynomials of the elements of $\mathbb{T}$ on $V = L \otimes K$ split over K. Then every system of eigenvalues $\phi\colon \mathbb{T} \to K$ takes values in $\mathcal{O}$; $\mathfrak{m}_\phi = \phi^{-1}(\varpi\mathcal{O})$ is a maximal ideal of $\mathbb{T}$; $\mathfrak{m}_\phi = \mathfrak{m}_\psi$ iff $\phi \equiv \psi \pmod{\varpi}$ on $\mathbb{T}$; and for each maximal ideal $\mathfrak{m}$,

$$e_{\mathfrak{m}} L \otimes K = \bigoplus_{\phi:\ \mathfrak{m}_\phi = \mathfrak{m}} V(\phi).$$

(If the eigenvalues are not in K, replace $\mathcal{O}$ by the ring of integers of a finite extension, Chapter 7.)

Proof. (i) $\mathbb{T}$ is a finite-dimensional commutative F-algebra, so $\mathbb{T} = \prod_i \mathbb{T}_i$ with local factors $\mathbb{T}_i = e_i\mathbb{T}$ (Theorem 3.93). The residue field $\mathbb{T}/\mathfrak{m}_i$ is generated over F by the images of the $t \in \mathbb{T}$. Each such image is a root of the minimal polynomial of t as an element of $\mathbb{T}$, which is the minimal polynomial of t as an operator ($\mathbb{T} \subseteq \mathrm{End}\, V$), a divisor of the characteristic polynomial, hence a product of linear factors over F; so the image lies in F, and $\mathbb{T}/\mathfrak{m}_i = F$. This gives a system of eigenvalues $\phi_i\colon \mathbb{T} \to \mathbb{T}/\mathfrak{m}_i = F$, and conversely every ϕ has a maximal kernel; so the ϕ correspond to the $\mathfrak{m}_i$. Put $V_i = e_iV$; then $V = \bigoplus V_i$, and $V_i \neq 0$ because $e_i \neq 0$ in $\mathbb{T} \subseteq \mathrm{End}\, V$. On V_i, $t - \phi_i(t)$ acts through the nilpotent maximal ideal of $\mathbb{T}_i$, so it is a nilpotent operator and $(t-\phi_i(t))^{\dim V} = 0$ there: $V_i \subseteq V(\phi_i)$. Conversely, if $v \in V(\phi_i)$ and $j \neq i$, take $t = e_j$: $\phi_i(e_j) = 0$, so $e_j^{\dim V} v = e_j v = 0$; hence $v = e_iv \in V_i$. So $V(\phi_i) = V_i$ and $e_{\phi_i} = e_i$. A common eigenvector: let $\mathfrak{n}$ be the maximal ideal of $\mathbb{T}_i$ and $c \geq 0$ the largest integer with $\mathfrak{n}^c V_i \neq 0$ (with $\mathfrak{n}^0 = \mathbb{T}_i$; it exists as $V_i \neq 0$ and $\mathfrak{n}$ is nilpotent); then $\mathfrak{n}^{c+1}V_i = 0$, so a nonzero $v \in \mathfrak{n}^c V_i$ is killed by $\mathfrak{n}$, and $tv = \phi_i(t)v$. Finally $e_iW \subseteq W \cap V_i$ for W stable, and $w = \sum e_i w$. (ii) $\mathbb{T}$ is a finitely generated $\mathcal{O}$-submodule of $\mathrm{End}_{\mathcal{O}}(L) \simeq \mathcal{O}^{n^2}$, hence finite free, and complete $\mathcal{O}$ makes Theorem 3.95 available. For ϕ a system of eigenvalues on V, $\phi(t)$ is an eigenvalue of t (by (i) over K), hence a root of the characteristic polynomial of t on L, which is monic with coefficients in $\mathcal{O}$; a root $x \in K$ of such a polynomial has $v(x) \geq 0$ (if $v(x) < 0$ the leading term has strictly smaller valuation than all others). So $\phi(\mathbb{T}) \subseteq \mathcal{O}$, and ϕ is an $\mathcal{O}$-algebra map, so $\mathbb{T} \to \mathcal{O} \to k$ is onto with kernel $\mathfrak{m}_\phi$, maximal. If $\mathfrak{m}_\phi = \mathfrak{m}_\psi = \mathfrak{m}$, the reductions $\bar\phi, \bar\psi\colon \mathbb{T} \to k$ both induce $\mathcal{O}$-algebra isomorphisms $\mathbb{T}/\mathfrak{m} \to k$, which coincide since $\mathbb{T}/\mathfrak{m}$ is generated by the image of $\mathcal{O}$ ($\mathbb{T}/\mathfrak{m} \simeq k$ via either, and k is generated by $\mathcal{O}$); conversely congruent systems have the same kernel modulo ϖ. For the last statement: $e_{\mathfrak{m}}$ acts on $V(\phi)$ as an idempotent whose only eigenvalue is $\phi(e_{\mathfrak{m}}) \in \{0,1\}$, so as the scalar $\phi(e_{\mathfrak{m}})$; and $\phi(e_{\mathfrak{m}}) \equiv 1$ iff $e_{\mathfrak{m}} \notin \mathfrak{m}_\phi$ iff $\mathfrak{m}_\phi = \mathfrak{m}$ (Theorem 3.95(ii)). Sum over ϕ using (i). □

A small example of (i): $A = \begin{pmatrix} 2 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix}$ on F^3 generates $\mathbb{T} = F[A]$ with two systems of eigenvalues, $A \mapsto 2$ and $A \mapsto 3$. Here $V(2) = Fe_1 + Fe_2$ and $V(3) = Fe_3$, and A is not diagonalisable on $V(2)$. The projection onto $V(2)$ is a polynomial in A, as the theorem says: $p(X) = 1 - (X-2)^2$ satisfies $p(3) = 0$, $p(2) = 1$ and $p'(2) = 0$, so $p(A)$ is 1 on $V(2)$ (where $(A-2)^2 = 0$) and 0 on $V(3)$; indeed $p(A) = \mathrm{diag}(1,1,0)$ (checked with PARI). The common eigenvector in $V(2)$ is e_1, spanning $(A-2)V(2)$, the last nonzero power of the maximal ideal

applied to $V(2)$, as in the proof. For (ii), replace the entry 3 by 5 and work on $L=\mathbb{Z}_3^3$. The systems $A\mapsto 2$ and $A\mapsto 5$ are now congruent modulo 3, so they have the same maximal ideal of $\mathbb{Z}_3[A]\simeq\mathbb{Z}_3[X]/((X-2)^2(X-5))$, which is local because $(X-2)^2(X-5)\equiv(X-2)^3 \pmod 3$; its only idempotents are 0 and 1, and $e_{\mathfrak{m}}L\otimes\mathbb{Q}_3=V(2)\oplus V(5)$ is everything. Over $\mathbb{Z}_\ell$ with $\ell\neq 3$ the reductions 2 and 5 differ, and the two generalised eigenspaces are separated by an idempotent of $\mathbb{Z}_\ell[A]$. Congruences between eigenvalues are exactly what glues generalised eigenspaces together integrally.

In the paper 3.101. In Lemma lem:crit, "$\mathbb{T}\otimes\mathbb{Q}=\mathbb{Q}\times\mathbb{T}'$ with $\mathbb{T}'$ acting faithfully on $f^{\perp}$" is Theorem 3.93 for $\mathbb{T}\otimes\mathbb{Q}$ together with the fact that the local factor through which ϕ_f factors is $\mathbb{Q}$ itself, which is multiplicity one for the newform f (Chapter 13; compare Proposition 3.110(ii)). In Theorem thm:twist, "$g^{\perp}$, the $\mathbb{T}$-stable complement of the g-line (the sum of the generalised eigenspaces of the other systems of eigenvalues)" is $\bigoplus_{\phi\neq\phi_g}V(\phi)$ of Theorem 3.100(i), applied to the algebra generated by the T_p, $p\nmid N_S$, over $\overline{\mathbb{Q}}$. In the proof of Lemma lem:step1, "The form h' lies in the sum of the generalised eigenspaces of the eigencharacters $\phi\neq\pi$ of $\mathbb{T}$ congruent to π modulo the maximal ideal above ℓ" is part (ii).

Proposition 3.102 (projecting a congruence to a local component)**.** *In Theorem 3.100(ii) let $\mathfrak{m}$ be a maximal ideal of $\mathbb{T}$ and $e=e_{\mathfrak{m}}$.*

(i) e maps L into L and every $\mathbb{T}$-stable subspace $W\subseteq V$ into itself, and fixes $V(\phi)$ pointwise when $\mathfrak{m}_\phi=\mathfrak{m}$.

(ii) If $x\in V(\phi)\cap L$ with $\mathfrak{m}_\phi=\mathfrak{m}$, $y\in L\cap W$ and $x\equiv y \pmod{\varpi^tL}$, then $x\equiv ey \pmod{\varpi^tL}$, and $ey\in L\cap W\cap eV$.

Proof. (i) $e\in\mathbb{T}$ and W is $\mathbb{T}$-stable; e acts on $V(\phi)$ by $\phi(e)=1$ (proof of Theorem 3.100(ii)). (ii) $ex=x$, and $e(x-y)\in e\varpi^tL\subseteq\varpi^tL$. □

In the paper 3.103. The proof of Lemma lem:step1 (the inequality $\geq$): "The idempotent $e_{\mathfrak{m}}$ of $\mathbb{T}_\ell$ fixes g^S (as π factors through $\mathbb{T}_{\mathfrak{m}}$) and preserves C and the integral forms, so $h'=e_{\mathfrak{m}}h$ lies in $C\cap S_2(\Gamma_0(N);\mathbb{Z}_\ell)$ and $g^S\equiv h' \pmod{\ell^t}$". This is Proposition 3.102(ii) with $x=g^S$, $W=C$ the complement of the line of g^S, and $y=h$.

Proposition 3.104 (semisimple and non-semisimple operators)**.** *Let $A\in\mathrm{End}_F(V)$ with V finite-dimensional over a field F, and let μ_A be its minimal polynomial.*

(i) A is semisimple *if every A-stable subspace has an A-stable complement. This holds iff μ_A is squarefree, iff $F[A]$ is reduced; for F perfect (of characteristic 0, or finite) it holds iff A is diagonalisable over an algebraic closure $\overline{F}$.*

(ii) If A has a cyclic vector (v with $v,Av,\dots,A^{n-1}v$ a basis), then μ_A equals the characteristic polynomial; so A is not semisimple as soon as the characteristic polynomial has a repeated root.

(iii) A commutative subalgebra $\mathbb{T}\subseteq\mathrm{End}_F(V)$ is reduced iff each of its elements is semisimple. If some $t\in\mathbb{T}$ is not semisimple, $\mathbb{T}$ contains a nonzero nilpotent element.

(iv) (Jordan-Chevalley.) For F perfect, $A=A_s+A_n$ with A_s semisimple, A_n nilpotent, $A_sA_n=A_nA_s$, and A_s, A_n polynomials in A; the decomposition is unique.

Proof. (i) $F[A] \simeq F[X]/(\mu_A)$. If $\mu_A = g^2 h$ with g nonconstant then $gh(A) \neq 0$ and $(gh)^2(A) = 0$; and if $\mu_A = \prod g_i$ with distinct irreducible g_i then $F[X]/(\mu_A) \simeq \prod F[X]/(g_i)$ is a product of fields (Chinese remainder theorem). So μ_A squarefree iff $F[A]$ reduced. If $F[A] = \prod F_i$ is a product of fields with idempotents e_i, an A-stable W is an $F[A]$-submodule, $W = \bigoplus e_i W$ with $e_i W$ an F_i-subspace of the F_i-vector space $e_i V$; choose F_i-complements C_i; then $\bigoplus C_i$ is an A-stable complement. If μ_A is not squarefree, let $N = gh(A)$ as above, $N \neq 0 = N^2$, and $W = \ker N \supseteq \operatorname{im} N \neq 0$. If $V = W \oplus C$ with C stable, then $N(C) \subseteq C \cap \operatorname{im} N \subseteq C \cap W = 0$, so $C \subseteq \ker N = W$, $C = 0$ and $N = 0$: a contradiction. For perfect F, an irreducible polynomial has distinct roots in $\overline{F}$; so μ_A is squarefree over F iff it has distinct roots in $\overline{F}$, iff A is diagonalisable over $\overline{F}$. (The minimal polynomial does not change under field extension, being determined by the linear dependences among $1, A, A^2, \ldots$.) (ii) No nonzero polynomial of degree $< n$ kills v, so $\deg \mu_A \geq n$, and μ_A divides the characteristic polynomial (Cayley-Hamilton). A repeated root makes μ_A non-squarefree. (iii) If $\mathbb{T}$ is reduced so is each $F[t] \subseteq \mathbb{T}$; conversely a nonzero nilpotent t has $\mu_t = X^k$ with $k \geq 2$. If t is not semisimple, $F[t]$ contains the nonzero nilpotent $gh(t)$. (iv) We do not prove this; see [58, Section 12.3] (section number not verified) or any text on linear algebra. □

Example 3.105 (the shift operator: U_p on oldforms)**.** Let V have basis $v_0, \ldots, v_e$ ($e \geq 1$) over a field F and let $Uv_j = v_{j-1}$ for $j \geq 1$.

(a) If $Uv_0 = av_0 - pv_1$ with $p \neq 0$, the characteristic polynomial of U is $X^{e-1}(X^2 - aX + p)$, and v_e is a cyclic vector ($U^j v_e = v_{e-j}$). So for $e \geq 3$ the eigenvalue 0 has a single Jordan block, of size $e - 1 \geq 2$, and U is not semisimple. Nevertheless every eigenvalue has an eigenvector: for $e \geq 2$, $U(v_0 - av_1 + pv_2) = (av_0 - pv_1) - av_0 + pv_1 = 0$; and if α, β are the roots of $X^2 - aX + p$, $U(v_0 - \beta v_1) = (a - \beta)v_0 - pv_1 = \alpha(v_0 - \beta v_1)$.

(b) If $Uv_0 = av_0$ with $a \neq 0$, the characteristic polynomial is $X^e(X - a)$, v_e is again cyclic, U is not semisimple for $e \geq 2$, and $U(v_0 - av_1) = 0$.

The characteristic polynomials (for $e \leq 4$, with a, p as indeterminates) and the cyclicity of v_e were checked with PARI. With $v_j = h(p^j z)$ for a newform h of level M, (a) is U_p on the span of the $h(p^j z)$ when $p \nmid M$, and (b) when $p \parallel M$ (Chapter 13); for instance at level 88 with $h = f_{11}$, $p = 2$, $a = a_2(f_{11}) = -2$ and $e = 3$, the characteristic polynomial is $X^2(X^2 + 2X + 2)$ and the algebra generated by U_2 on this span is not reduced (Proposition 3.104(iii)).

In the paper 3.106. Lemma lem:old: "The operator U_p is not semisimple on this span when 0 is a repeated eigenvalue, but each listed eigenvalue has an eigenvector" is Example 3.105, with the eigenvectors the p-stabilisations $h - \beta_p h(pz)$, $h - \alpha_p h(pz)$ and the depleted forms. The same example shows that the full Hecke algebra need not be reduced, which matters in Lemma lem:ddt417 (Proposition 3.110(iv)).

Lemma 3.107 (common eigenvectors)**.** *Let F be algebraically closed and $V \neq 0$ finite-dimensional over F.*

(i) Let $A_1, \ldots, A_k$ be commuting operators on V and $\lambda = (\lambda_1, \ldots, \lambda_k) \in F^k$, with joint generalised eigenspace $V(\lambda) = \bigcap_i \ker(A_i - \lambda_i)^{\dim V}$. If $V(\lambda) \neq 0$, it contains a common eigenvector of the A_i, which can be chosen to be an eigenvector of every element of any commutative algebra $\mathbb{T} \subseteq \operatorname{End}_F(V)$ containing the A_i.

(ii) If $V = V_1 \otimes \cdots \otimes V_k$ and A_i acts on the i-th factor (as $1 \otimes \cdots \otimes A_i \otimes \cdots \otimes 1$), then $V(\lambda) = V_1(\lambda_1) \otimes \cdots \otimes V_k(\lambda_k)$, which is nonzero iff each λ_i is an eigenvalue of A_i on V_i.

Proof. (i) $V(\lambda)$ is stable under $\mathbb{T}$, since $\mathbb{T}$ commutes with the A_i. Apply Theorem 3.100(i) to the image of $\mathbb{T}$ in $\operatorname{End} V(\lambda)$ (characteristic polynomials split as F is algebraically closed): $V(\lambda)$ contains a common eigenvector v of $\mathbb{T}$, and $A_i v = \lambda_i v$ because $A_i - \lambda_i$ is nilpotent on $V(\lambda)$. (ii) Decompose each $V_i = \bigoplus_\mu V_i(\mu)$ into generalised eigenspaces of A_i; then V is the direct sum of the $V_1(\mu_1) \otimes \cdots \otimes V_k(\mu_k)$. On such a summand $A_i - \mu_i$ is nilpotent, and if $\mu_i \neq \lambda_i$ then $A_i - \lambda_i$ is invertible on it. So the summands in $V(\lambda)$ are exactly those with $\mu = \lambda$. □

In the paper 3.108. Lemma lem:old: "Since V is the tensor product of these local spaces and $\mathbb{T}$ is commutative, for every choice of one such eigenvalue μ_p at each $p \mid N/M$ there is a common eigenform $g \in V \otimes \overline{\mathbb{Q}}$ of all of $\mathbb{T}$". Here $V = \bigotimes_{p|N/M} \operatorname{span}\{h(p^j z) : 0 \le j \le e_p\}$, with U_p acting on the p-th factor, and Lemma 3.107(ii) then (i) give g.

3.11 Congruence ideals, Gorenstein algebras, and the ingredients of Lemma lem:ddt417

This section assembles the previous ones into the commutative algebra of congruences. A homomorphism $\pi\colon \mathbb{T} \to \mathcal{O}$ (the eigencharacter of a form) has a *congruence ideal* $\eta = \pi(\operatorname{Ann}_{\mathbb{T}} \ker \pi)$, which measures how far the factor of π is congruent to the rest of $\mathbb{T}$; it is the paper's r in Lemma lem:crit and the η of Lemma lem:ddt417. We prove every module-theoretic step of the proof of Lemma lem:ddt417 and stop short of the lemma itself, which Chapter 20 proves; we then define Gorenstein algebras and prove the freeness criterion behind Remark rem:free. Throughout, $\mathcal{O}$ is a discrete valuation ring with fraction field K, and $\mathbb{T}$ is a finite free $\mathcal{O}$-algebra.

Definition 3.109 (congruence ideal and congruence module)**.** Let $\pi\colon \mathbb{T} \to \mathcal{O}$ be a surjective $\mathcal{O}$-algebra homomorphism, $\wp = \ker \pi$ and $I = \operatorname{Ann}_{\mathbb{T}}(\wp)$. The *congruence ideal* of π is $\eta = \pi(I) \subseteq \mathcal{O}$, and the *congruence module* is $\mathbb{T}/(\wp + I)$, which is isomorphic to $\mathcal{O}/\eta$ by Theorem 3.8(iv). Let $\pi_K\colon \mathbb{T}_K \to K$ be the extension of π and $\mathbb{T}_K = A_\pi \times \mathbb{T}'_K$ the decomposition in which A_π is the local factor through which π_K factors (Theorem 3.94(iii)), with idempotent e_π.

The idea behind the definition: over K the factor of π is cut out by the idempotent e_π, but e_π need not lie in $\mathbb{T}$. The ideal $I = \operatorname{Ann}_{\mathbb{T}}(\wp)$ consists of the elements of $\mathbb{T}$ that "live only on the factor of π" (they are killed by everything that vanishes there), and when $\eta \neq 0$ they are exactly the integral multiples $ae_\pi \in \mathbb{T}$ (Proposition 3.110(iii)). So η is the ideal of denominators of e_π, and the congruence module $\mathcal{O}/\eta$ measures how far the factor of π is from splitting off integrally. In $\mathbb{T}_r = \{(a,b) : a \equiv b \bmod \varpi^r\}$ with $\pi(a,b) = a$, the idempotent $(1,0)$ is not in $\mathbb{T}_r$ but $\varpi^r(1,0)$ is, and $\eta = \varpi^r\mathcal{O}$: the two eigencharacters $(a,b) \mapsto a$ and $(a,b) \mapsto b$ of $\mathbb{T}_r$ are congruent modulo ϖ^r and not modulo ϖ^{r+1} (Example 3.112(a)).

Proposition 3.110 (congruence ideals)**.** *In the setting of Definition 3.109:*

(i) $I \neq 0$; indeed $I = \mathbb{T} \cap \operatorname{Ann}_{\mathbb{T}_K}(\wp_K)$, where $\wp_K = \wp \otimes K = \ker \pi_K$.

(ii) The following are equivalent: (a) $\eta \neq 0$; (b) $\wp \cap I = 0$; (c) $A_\pi = K$, that is, $\mathbb{T}_K = K \times \mathbb{T}'_K$ with π_K the first projection.

(iii) *If $\eta \neq 0$: $\pi|_I : I \to \eta$ is an isomorphism, so I is free of rank one over $\mathcal{O}$, generated by any $t \in I$ with $\pi(t)\mathcal{O} = \eta$; $\mathrm{Ann}_{\mathbb{T}}(I) = \wp$; $I = \mathbb{T} \cap (K \times 0)$ and $\wp = \mathbb{T} \cap (0 \times \mathbb{T}'_K)$; and $\eta = \{a \in \mathcal{O} : ae_\pi \in \mathbb{T}\}$, the "denominator" of the idempotent e_π.*

(iv) *If $\mathbb{T}_K$ is reduced, (c) holds automatically. $\mathbb{T}_K$ need not be reduced (Example 3.105); then (c) must be checked directly. For the eigencharacter of a newform it is multiplicity one (Chapter 13).*

(v) *(Compatibility.) If $\mathcal{O}$ is complete and $\mathfrak{m} = \mathfrak{m}_\pi$, write $\mathbb{T} = \mathbb{T}_\mathfrak{m} \times \mathbb{T}''$ with $\mathbb{T}'' = \prod_{\mathfrak{m}' \neq \mathfrak{m}} \mathbb{T}_{\mathfrak{m}'}$ (Theorem 3.95). Then $\wp = \wp_\mathfrak{m} \times \mathbb{T}''$ with $\wp_\mathfrak{m} = \ker(\pi|_{\mathbb{T}_\mathfrak{m}})$, and $\mathrm{Ann}_{\mathbb{T}}(\wp) = \mathrm{Ann}_{\mathbb{T}_\mathfrak{m}}(\wp_\mathfrak{m}) \times 0$; so $\eta(\mathbb{T}, \pi) = \eta(\mathbb{T}_\mathfrak{m}, \pi|_{\mathbb{T}_\mathfrak{m}})$: the congruence ideal is computed in $\mathbb{T}_\mathfrak{m}$. The other local factors lie in $\wp$, and their component of the annihilator is 0. For a flat extension $\mathcal{O} \to \mathcal{O}'$ of discrete valuation rings (for example $\mathbb{Z}_{(\ell)} \to \mathbb{Z}_\ell$), $\eta(\mathbb{T} \otimes \mathcal{O}', \pi \otimes \mathcal{O}') = \eta\mathcal{O}'$.*

Proof. (i) For $t \in \mathbb{T}$, $t\wp = 0$ iff $t\wp_K = 0$, as $\wp_K = K\wp$. Write $\mathbb{T}_K = A_\pi \times \mathbb{T}'_K$; then $\wp_K = \mathfrak{m}_{A_\pi} \times \mathbb{T}'_K$ and $\mathrm{Ann}_{\mathbb{T}_K}(\wp_K) = \mathrm{Ann}_{A_\pi}(\mathfrak{m}_{A_\pi}) \times 0$. In the local Artinian ring A_π the maximal ideal is nilpotent (Theorem 3.93); if $\mathfrak{m}_{A_\pi}^{c+1} = 0 \neq \mathfrak{m}_{A_\pi}^{c}$ (with $\mathfrak{m}^0 = A_\pi$), then $0 \neq \mathfrak{m}_{A_\pi}^{c} \subseteq \mathrm{Ann}(\mathfrak{m}_{A_\pi})$. Every nonzero $y \in \mathbb{T}_K$ has a nonzero multiple $\varpi^s y \in \mathbb{T}$; so $I \neq 0$. (ii) (a)⇒(b): choose $t \in I$ with $\pi(t)$ a generator of η. For $x \in \wp \cap I$ write $\pi(t)x = tx + (\pi(t) - t)x$. Here $tx \in I\wp = 0$, and $(\pi(t) - t)x \in \wp I = 0$ because $\pi(t) - t \in \wp$. So $\pi(t)x = 0$, and $x = 0$ because $\mathbb{T}$ is torsion-free and $\pi(t) \neq 0$. (b)⇒(a): if $\eta = 0$ then $I \subseteq \wp$, so $\wp \cap I = I \neq 0$ by (i). (a)⇔(c): if A_π is not a field, then $\mathfrak{m}_{A_\pi} \neq 0$ and $\mathrm{Ann}_{A_\pi}(\mathfrak{m}_{A_\pi}) \subseteq \mathfrak{m}_{A_\pi}$ (a unit cannot kill a nonzero ideal), so $I \subseteq \mathbb{T} \cap (\mathfrak{m}_{A_\pi} \times 0) \subseteq \wp_K$ and $\eta = \pi(I) = 0$. If A_π is a field, it is K (π_K maps it onto K as a K-algebra). Then $e_\pi = (1, 0)$ has a nonzero multiple $ae_\pi \in \mathbb{T}$ with $a \in \mathcal{O}$; it kills $\wp_K = 0 \times \mathbb{T}'_K$, so lies in I, and $\pi(ae_\pi) = a \neq 0$. (iii) The kernel of $\pi|_I$ is $\wp \cap I = 0$, and its image is η by definition; $\eta \simeq \mathcal{O}$. If $xI = 0$ then $\pi(x)\pi(t) = \pi(xt) = 0$, so $\pi(x) = 0$; conversely $\wp I = 0$. By (c), $\wp_K = 0 \times \mathbb{T}'_K$ and $\mathrm{Ann}_{\mathbb{T}_K}(\wp_K) = K \times 0$, so (i) gives $I = \mathbb{T} \cap (K \times 0)$, and $\wp = \mathbb{T} \cap \ker \pi_K = \mathbb{T} \cap (0 \times \mathbb{T}'_K)$. An element of $\mathbb{T} \cap (K \times 0)$ is ce_π with $c = \pi_K(ce_\pi)$; so $\eta = \{c : ce_\pi \in \mathbb{T}\}$ (such c lie in $\mathcal{O}$ automatically). (iv) If $\mathbb{T}_K$ is reduced its local factors are fields (Theorem 3.93(iii)), and $A_\pi = K$ as in (ii). (v) π kills $\mathbb{T}''$ (Theorem 3.95(iv)), so $\wp = \wp_\mathfrak{m} \times \mathbb{T}''$. An element (a, b) kills $\wp$ iff $a\wp_\mathfrak{m} = 0$ and $b\mathbb{T}'' = 0$, that is, $b = 0$; so $\mathrm{Ann}_{\mathbb{T}}(\wp) = \mathrm{Ann}_{\mathbb{T}_\mathfrak{m}}(\wp_\mathfrak{m}) \times 0$, and $\pi(\mathrm{Ann}_{\mathbb{T}} \wp) = \pi(\mathrm{Ann}_{\mathbb{T}_\mathfrak{m}} \wp_\mathfrak{m})$. For a flat $\mathcal{O} \to \mathcal{O}'$, $\ker(\pi \otimes \mathcal{O}') = \wp \otimes \mathcal{O}'$ and $\mathrm{Ann}(\wp \otimes \mathcal{O}') = I \otimes \mathcal{O}'$ (Proposition 3.29(iii); $\wp$ is finitely generated), so $\eta(\mathbb{T} \otimes \mathcal{O}') = \pi(I)\mathcal{O}'$. □

In the paper 3.111. Lemma lem:crit: "$I = \mathbb{T} \cap (0 \times \mathbb{T}')$ and $J = \mathbb{T} \cap (\mathbb{Q} \times 0)$, so $I \cap J = 0$ and $\mathbb{T}/(I + J) \simeq \mathbb{Z}/\phi_f(J)$" is Proposition 3.110(iii) over $\mathcal{O} = \mathbb{Z}_{(\ell)}$ (or over $\mathbb{Z}$ verbatim, the proofs using only that $\mathbb{Z}$ is a principal ideal domain), with $\pi = \phi_f$, $\wp = \ker \phi_f$ (the paper's I there) and $\mathrm{Ann}(\wp)$ (the paper's J); Appendix B, convention B-C13(c), explains the clash of letters between Lemmas lem:crit and lem:ddt417. In Lemma lem:ddt417 the paper proves $\wp \cap I = 0$ by the argument of (ii), and remarks that reducedness would not do. The paragraph after Lemma lem:hecke says (and Step 1 of the proof of Theorem thm:quant says the same with $\ker \pi$) that "the congruence ideal is computed in $\mathbb{T}_\mathfrak{m}$: the other local factors of $\mathbb{T} \otimes \mathbb{Z}_\ell$ lie in the kernel $\wp$, ϕ_f factors through $\mathbb{T}_\mathfrak{m}$, and $\mathrm{Ann}(\wp)$ decomposes along the idempotents": this is (v).

Example 3.112 (toy congruences)**.** All entries were computed by hand from the definitions (and, for $\varpi = 3$, $r = 1, 2$, checked by computer).

$\mathbb{T}$, π	$\wp$	$I = \mathrm{Ann}_{\mathbb{T}}(\wp)$	η	Gorenstein?
(a) $\mathbb{T}_r$, $\pi(a,b) = a$	$0 \times \varpi^r\mathcal{O}$	$\varpi^r\mathcal{O} \times 0$	$\varpi^r\mathcal{O}$	yes
(b) $\mathbb{Z}[x]/(x^2-4)$, $\pi(x) = 2$	$\mathbb{Z}(x-2)$	$\mathbb{Z}(x+2)$	$4\mathbb{Z}$	yes
(c) $\mathbb{T}_3^\flat$, $\pi(a,b,c) = a$	$0 \times \varpi\mathcal{O} \times \varpi\mathcal{O}$	$\varpi\mathcal{O} \times 0 \times 0$	$\varpi\mathcal{O}$	no
(d) $\mathcal{O}[x]/(x^2)$, $\pi(x) = 0$	$\mathcal{O}x$	$\mathcal{O}x$	0	yes
(e) $\mathbb{Z}[x]/(x^2(x-1))$, $\pi(x) = 0$	(x)	$\mathbb{Z}(x-x^2)$	0	yes
(e′) $\mathbb{Z}[x]/(x^2(x-1))$, $\pi(x) = 1$	$(x-1)$	$\mathbb{Z}x^2$	$\mathbb{Z}$	yes

Here $\mathbb{T}_r = \{(a,b) \in \mathcal{O}^2 : a \equiv b \bmod \varpi^r\}$ and $\mathbb{T}_3^\flat = \{(a,b,c) \in \mathcal{O}^3 : a \equiv b \equiv c \bmod \varpi\}$. (a) $\mathbb{T}_r \simeq \mathcal{O}[x]/(x(x-\varpi^r))$ with $x = (\varpi^r, 0)$; $e_\pi = (1,0) = x/\varpi^r$, with denominator ϖ^r; the congruence module is $\mathcal{O}/\varpi^r$: "two eigenforms congruent modulo ϖ^r". (b) $(a+bx)(x-2) = (a-2b)x+(4b-2a)$ vanishes iff $a = 2b$, so $I = \mathbb{Z}(x+2)$, $\pi(x+2) = 4$, $e_\pi = (x+2)/4$, congruence module $\mathbb{Z}/4$; under $\mathbb{T} \simeq \{(a,b) : a \equiv b \bmod 4\}$ this is (a) with $\varpi^r = 4$. (c) An element (a,b,c) kills $\wp$ iff $b = c = 0$; three pairwise congruent eigenforms, congruence ideal $\varpi\mathcal{O}$. (d) Here $\wp \cap I = \mathcal{O}x \neq 0$ and $\eta = 0$: the factor of π in $\mathbb{T}_K = K[x]/(x^2)$ is not a field. (e) For $\pi(x) = 0$ the factor of $\mathbb{T}_{\mathbb{Q}}$ is $\mathbb{Q}[x]/(x^2)$; the annihilator of x consists of the $c(x^2-x)$ (use $x^3 = x^2$), and $\pi(x-x^2) = 0$. For $\pi(x) = 1$ the factor is $\mathbb{Q}$; $I = \mathbb{Z}x^2$ with x^2 an idempotent of $\mathbb{T}$, so $\eta = \mathbb{Z}$ and the congruence module is 0: no congruence. The Gorenstein column is Proposition 3.115(iii).

Proposition 3.113 (the module ingredients of Lemma lem:ddt417)**.** *In the setting of Definition 3.109 with $\eta \neq 0$, choose $t \in I$ with $\pi(t)\mathcal{O} = \eta$. Let L be a $\mathbb{T}$-module that is free of finite rank over $\mathcal{O}$, with a perfect $\mathcal{O}$-bilinear pairing for which every element of $\mathbb{T}$ is self-adjoint. Then:*

(i) $L[\wp]$ *and* $L[I]$ *are saturated in* L.

(ii) $L[\wp] \cap L[I] = 0$*, so the sum* $L[\wp] + L[I]$ *is direct.*

(iii) $L[\wp]^\perp = L[I] = {}^\perp L[\wp]$ *and* $L[I]^\perp = L[\wp] = {}^\perp L[I]$.

(iv) More generally $(\mathfrak{a}L)^\perp = L[\mathfrak{a}]$ *for every ideal* $\mathfrak{a} \subseteq \mathbb{T}$.

(v) For every $x \in L$, $\pi(t)x = tx + (\pi(t)-t)x$ *with* $tx \in L[\wp]$ *and* $(\pi(t)-t)x \in L[I]$*; so* $Q = L/(L[\wp] \oplus L[I])$ *is killed by* η.

(vi) If $L \simeq \mathbb{T}^r$ *as* $\mathbb{T}$*-modules, then* $L[\wp] = I^r$ *(free of rank* r *over* $\mathcal{O}$*),* $L[I] = \wp^r$*, and* $Q \simeq (\mathbb{T}/(\wp+I))^r \simeq (\mathcal{O}/\eta)^r$.

Proof. (i) Proposition 3.49(iii), applied to the action of $\mathbb{T}$ on the lattice L and the ideals $\wp$ and I. (ii) $\pi(t) = t + (\pi(t)-t) \in I + \wp$ (here $\pi(t)$ stands for $\pi(t) \cdot 1 \in \mathbb{T}$, and $\pi(\pi(t)-t) = 0$), so an element killed by $\wp$ and by I is killed by $\pi(t) \neq 0$, hence is 0 (L is torsion-free over $\mathcal{O}$). Directness is Proposition 3.13. (iii) Let $x \in L[\wp]$ and $y \in L[I]$. Since $(\pi(t)-t)x \in \wp x = 0$, $\pi(t)\langle x,y\rangle = \langle tx,y\rangle = \langle x,ty\rangle = 0$, and $\langle x,y\rangle = 0$; likewise $\langle y,x\rangle = 0$. So $L[I] \subseteq L[\wp]^\perp \cap {}^\perp L[\wp]$. Conversely let $y \in L[\wp]^\perp$. For $s \in I$ and $z \in L$, $sz \in L[\wp]$ (as $\wp s = 0$), so $\langle z, sy\rangle = \langle sz, y\rangle = 0$; by perfectness $sy = 0$, and $y \in L[I]$. The same argument with the arguments exchanged gives ${}^\perp L[\wp] = L[I]$. Then $L[I]^\perp = ({}^\perp L[\wp])^\perp = L[\wp]$ and ${}^\perp L[I] = {}^\perp(L[\wp]^\perp) = L[\wp]$ by Proposition 3.83(ii), $L[\wp]$ being saturated. (iv) is Proposition 3.89(ii). (v) $\wp tx \subseteq \wp Ix = 0$; and for $s \in I$, $s(\pi(t)-t) \in I\wp = 0$. (vi) Componentwise, $\mathbb{T}^r[\mathfrak{a}] = \mathrm{Ann}_{\mathbb{T}}(\mathfrak{a})^r$ (Proposition 3.68(iii)); $\mathrm{Ann}_{\mathbb{T}}(\wp) = I$ and $\mathrm{Ann}_{\mathbb{T}}(I) = \wp$ (Proposition 3.110(iii)). So $Q = \mathbb{T}^r/(I^r \oplus \wp^r) = (\mathbb{T}/(I+\wp))^r$, and $\mathbb{T}/(\wp+I) \simeq \mathcal{O}/\eta$. □

Definition 3.114 (Gorenstein algebras)**.** Let $\mathbb{T}^\vee = \mathrm{Hom}_{\mathcal{O}}(\mathbb{T}, \mathcal{O})$, a $\mathbb{T}$-module by $(t\varphi)(u) = \varphi(tu)$. The finite free $\mathcal{O}$-algebra $\mathbb{T}$ is *Gorenstein* if $\mathbb{T}^\vee$ is free of rank one as a $\mathbb{T}$-module.

The module $\mathbb{T}^\vee$ is the abstract version of a space of forms: for the Hecke algebra over $\mathbb{Z}$ the pairing $\langle g,t\rangle = a_1(tg)$ identifies $S_2(\Gamma_0(N);\mathbb{Z})$ with $\mathbb{T}^\vee$ (Proposition 3.91(i) and Paper link 3.92). Freeness of rank one says that this space of forms is a copy of $\mathbb{T}$ itself, generated by one element, a property closely tied to multiplicity one (Theorem 3.116). It fails for the algebra $\mathbb{T}_3^\flat$ of three pairwise congruent eigenforms (Proposition 3.115(iii)), whose reduction $k[u,w]/(u^2,uw,w^2)$ has a two-dimensional socle.

Proposition 3.115 (Gorenstein criteria)**.** *(i) $\mathbb{T}$ is Gorenstein iff there is a perfect $\mathcal{O}$-bilinear pairing $\mathbb{T}\times\mathbb{T}\to\mathcal{O}$ with $\langle st,u\rangle = \langle s,tu\rangle$; one may take $\langle s,t\rangle = \lambda(st)$ for a generator λ of $\mathbb{T}^\vee$.*

(ii) If $\mathcal{O}$ is complete, $\mathbb{T}$ is Gorenstein iff each local factor $\mathbb{T}_\mathfrak{m}$ is. If $\mathbb{T}$ is local, with maximal ideal $\mathfrak{m}$ and residue field $k_\mathbb{T}$, the following are equivalent: $\mathbb{T}$ is Gorenstein; $\dim_{k_\mathbb{T}}(\mathbb{T}/\varpi\mathbb{T})[\mathfrak{m}] = 1$ (the socle *of $\mathbb{T}/\varpi\mathbb{T}$ is a line); $\dim_{k_\mathbb{T}} \mathbb{T}^\vee/\mathfrak{m}\mathbb{T}^\vee = 1$.*

(iii) Examples: $\mathcal{O}[x]/(f)$ for monic f is Gorenstein; $\mathbb{T}_r$ of Example 3.112(a) is Gorenstein; $\mathbb{T}_3^\flat$ of (c) is not, although $\mathbb{T}_3^\flat\otimes K = K^3$ is reduced; $\mathcal{O}[x]/(x^2)$ is Gorenstein and not reduced.

(iv) Complete intersections (quotients $\mathcal{O}[[x_1,\dots,x_n]]/(f_1,\dots,f_n)$ that are finite free over $\mathcal{O}$) are Gorenstein; and for $\mathbb{T}$ local Gorenstein and π as in Definition 3.109, Wiles's numerical criterion compares η with $\wp/\wp^2$ (stated; see Chapter 20).

Proof. (i) If λ generates $\mathbb{T}^\vee$ freely, $s\mapsto s\lambda = \lambda(s\cdot)$ is an isomorphism $\mathbb{T}\to\mathbb{T}^\vee$, which says that $\lambda(st)$ is perfect. Conversely, given the pairing, $s\mapsto\langle s,-\rangle$ is a $\mathbb{T}$-linear isomorphism $\mathbb{T}\to\mathbb{T}^\vee$ (Proposition 3.91(i) with $S=\mathbb{T}$). (ii) $\mathbb{T}^\vee = \prod_\mathfrak{m}\mathbb{T}^\vee_\mathfrak{m}$ compatibly with $\mathbb{T} = \prod\mathbb{T}_\mathfrak{m}$, and a module over a product is free of rank one iff each component is. Let $\mathbb{T}$ be local and $A = \mathbb{T}/\varpi\mathbb{T}$, a local k-algebra with maximal ideal $\bar{\mathfrak{m}} = \mathfrak{m}/\varpi\mathbb{T}$ and $A/\bar{\mathfrak{m}} = k_\mathbb{T}$. As $\mathbb{T}$ is free, $\mathbb{T}^\vee/\varpi\mathbb{T}^\vee = \mathrm{Hom}_k(A,k) =: A'$. Under the perfect pairing $A\times A'\to k$, $(x,\varphi)\mapsto\varphi(x)$, the orthogonal of the subspace $\bar{\mathfrak{m}}A'$ is $\{x : \varphi(ax) = 0\ \forall a\in\bar{\mathfrak{m}},\varphi\in A'\} = A[\bar{\mathfrak{m}}]$. So $\dim_k \mathbb{T}^\vee/\mathfrak{m}\mathbb{T}^\vee = \dim_k A'/\bar{\mathfrak{m}}A' = \dim_k A[\bar{\mathfrak{m}}]$, and dividing by $[k_\mathbb{T}:k]$ gives the equality of $k_\mathbb{T}$-dimensions. By Nakayama (Theorem 3.35(iii)), $\dim_{k_\mathbb{T}}\mathbb{T}^\vee/\mathfrak{m}\mathbb{T}^\vee = 1$ iff $\mathbb{T}^\vee$ is cyclic, $\mathbb{T}\twoheadrightarrow\mathbb{T}^\vee$. Both are free $\mathcal{O}$-modules of the same rank, so this surjection is an isomorphism (compose with an $\mathcal{O}$-isomorphism $\mathbb{T}^\vee\simeq\mathbb{T}$ and use Lemma 3.32(b)), and $\mathbb{T}^\vee$ is free of rank one. (iii) For f monic of degree n, with basis $1,x,\dots,x^{n-1}$, let λ be the coefficient of x^{n-1}. Then $\lambda(x^ix^j) = 0$ for $i+j<n-1$ and $=1$ for $i+j=n-1$, so the Gram matrix of $\lambda(st)$ is triangular with respect to the antidiagonal, with 1's on it, and has determinant ±1; apply (i). This covers $\mathcal{O}[x]/(x^2)$ and $\mathbb{T}_r\simeq\mathcal{O}[x]/(x(x-\varpi^r))$. Directly for $\mathbb{T}_r$: $\lambda(a,b) = (a-b)/\varpi^r$ is $\mathcal{O}$-valued on $\mathbb{T}_r$, and in the basis $(1,1)$, $(\varpi^r,0)$ the Gram matrix of $\lambda(st)$ is $\begin{pmatrix}0&1\\1&\varpi^r\end{pmatrix}$, of determinant -1. For $\mathbb{T}_3^\flat$, local with basis $(1,1,1)$, $u=(\varpi,0,0)$, $w=(0,\varpi,0)$: modulo ϖ, $u^2=\varpi u\equiv0$, $uw=0$, $w^2\equiv0$, so $\mathbb{T}_3^\flat/\varpi = k[u,w]/(u^2,uw,w^2)$, whose socle $ku+kw$ has dimension 2. (iv) We do not prove this; see [62, Chapter 21] and [38, Section 4]. □

Theorem 3.116 (a freeness criterion in the style of Mazur)**.** *Let $\mathbb{T}$ be a local finite free $\mathcal{O}$-algebra, with maximal ideal $\mathfrak{m}$ and residue field $k_\mathbb{T}$, and let $L\neq0$ be a $\mathbb{T}$-module, free of finite rank over $\mathcal{O}$, with a perfect $\mathcal{O}$-bilinear pairing for which every element of $\mathbb{T}$ is self-adjoint. Suppose*

(a) $\dim_{k_\mathbb{T}} L/\mathfrak{m}L = d$, and

(b) $\mathrm{rank}_\mathcal{O} L = d\cdot\mathrm{rank}_\mathcal{O}\mathbb{T}$.

Then $L \simeq \mathbb{T}^d$ as $\mathbb{T}$-modules, and $\mathbb{T}$ is Gorenstein.

Proof. L is a finitely generated $\mathbb{T}$-module (it is even finitely generated over $\mathcal{O}$), so by Nakayama (Theorem 3.35(iii)) any d elements whose images form a $k_{\mathbb{T}}$-basis of $L/\mathfrak{m}L$ generate it, and there is a surjection $\mathbb{T}^d \twoheadrightarrow L$. Both are free over $\mathcal{O}$ of rank $d \operatorname{rank} \mathbb{T}$, by (b), so it is an isomorphism: composing with an $\mathcal{O}$-isomorphism $L \simeq \mathbb{T}^d$ gives a surjective endomorphism of a finitely generated module, which is bijective by Lemma 3.32(b) (as in the proof of Proposition 3.115(ii)). The pairing gives a $\mathbb{T}$-linear isomorphism $L \simeq L^\vee$, $y \mapsto \langle -, y\rangle$ (linear because $\langle -, ty\rangle = \langle t\cdot, y\rangle$), and $L^\vee \simeq (\mathbb{T}^d)^\vee = (\mathbb{T}^\vee)^d$ (Hom out of a finite direct sum, Proposition 3.19(i)). So $(\mathbb{T}^\vee)^d \simeq \mathbb{T}^d$ as $\mathbb{T}$-modules, and reducing modulo $\mathfrak{m}$, $(\mathbb{T}^\vee/\mathfrak{m}\mathbb{T}^\vee)^d \simeq k_{\mathbb{T}}^d$; comparing $k_{\mathbb{T}}$-dimensions, $d \dim_{k_{\mathbb{T}}} \mathbb{T}^\vee/\mathfrak{m}\mathbb{T}^\vee = d$, and since $d \geq 1$ ($L \neq 0$, so $L/\mathfrak{m}L \neq 0$ by Nakayama), $\dim_{k_{\mathbb{T}}} \mathbb{T}^\vee/\mathfrak{m}\mathbb{T}^\vee = 1$ and $\mathbb{T}$ is Gorenstein by Proposition 3.115(ii). □

In the paper 3.117. Remark rem:free: "Freeness of $H^1(X_0(N), \mathbb{Z}_\ell)_{\mathfrak{m}}$ over $\mathbb{T}_{\mathfrak{m}}$ holds when $J_0(N)[\mathfrak{m}]$ is two-dimensional, since the localised Hecke algebra is then Gorenstein and the Tate module is free of rank two". In Theorem 3.116 take $\mathcal{O} = \mathbb{Z}_\ell$, $\mathbb{T} = \mathbb{T}_{\mathfrak{m}}$, $L = H^1(X_0(N), \mathbb{Z}_\ell)_{\mathfrak{m}}$ with the pairing $\hat{\delta}_!$ (perfect on the $\mathfrak{m}$-component by Proposition 3.89(iii)), and $d = 2$. Hypothesis (a) is the two-dimensionality of $J_0(N)[\mathfrak{m}]$, transported to $L/\mathfrak{m}L$ by duality, and (b) is a rank count from the Eichler-Shimura isomorphism; both are Chapter 14. The conclusion $L \simeq \mathbb{T}_{\mathfrak{m}}^2$ is the hypothesis of the equality clause of Lemma lem:ddt417. After Proposition prop:pullback the paper does not need this for Theorems thm:main and thm:quant.

Remark 3.118 (the statement of Lemma lem:ddt417, and where each step is proved). In the book's notation the paper's Lemma lem:ddt417 reads: *let $\mathbb{T}$ be a finite free $\mathcal{O}$-algebra acting on a module L that is free of finite rank over $\mathcal{O}$, with a perfect pairing for which $\mathbb{T}$ is self-adjoint; let $\pi\colon \mathbb{T} \twoheadrightarrow \mathcal{O}$, $\wp = \ker \pi$, $I = \operatorname{Ann}_{\mathbb{T}}(\wp)$ and $\eta = \pi(I)$; suppose $L[\wp]$ has rank d and Gram determinant $\Delta \neq 0$. Then $v(\Delta) \leq d\, v(\eta)$, that is, $\eta^d \subseteq \Delta\mathcal{O}$, with equality if L is free over $\mathbb{T}$.* It is proved in Chapter 20. Every step except the final count is proved in this chapter:

step of the paper's proof	proved in
$\wp \cap I = 0$ when $\eta \neq 0$	Proposition 3.110(ii)
$L[\wp] + L[I]$ is direct	Proposition 3.113(ii)
$Q = L/(L[\wp] \oplus L[I])$ is killed by η	Proposition 3.113(v)
$L[\wp]$ is saturated	Proposition 3.49(iii), Proposition 3.113(i)
$L/L[\wp]^\perp \simeq \operatorname{Hom}(L[\wp], \mathcal{O})$	Theorem 3.84(i)
$L[\wp]^\perp = L[I]$	Proposition 3.113(iii)
$Q \simeq \operatorname{coker}(L[\wp] \to L[\wp]^\vee)$, of length $v(\Delta)$	Theorem 3.84(ii)
Q is generated by d elements	Theorem 3.84(ii) ($L[\wp]^\vee \simeq \mathcal{O}^d$ surjects onto Q)
if $L \simeq \mathbb{T}^d$, $Q \simeq (\mathcal{O}/\eta)^d$	Proposition 3.113(vi)
the Gram determinant in rank two is η^2	Proposition 3.87(ii)

The remaining step is that a module generated by d elements and killed by η is a quotient of $(\mathcal{O}/\eta)^d$, of length at most $d\, v(\eta)$. *Checks on the toy algebra* $\mathbb{T}_r$ (all computed): with $L = \mathbb{T}_r$ and $\langle s, u\rangle = \lambda(su)$, $\lambda(a, b) = (a - b)/\varpi^r$, one has $L[\wp] = I = \mathcal{O}(\varpi^r, 0)$, $d = 1$ and $\Delta = \lambda((\varpi^r, 0)^2) = \varpi^r$, so $v(\Delta) = r = d\, v(\eta)$ (free case, equality). With $L = \mathcal{O}^2$, $\mathbb{T}_r$ acting diagonally and the standard pairing, $L[\wp] = \mathcal{O}e_1$ and $\Delta = 1$, so $0 = v(\Delta) < r$ (strict inequality; L is not free over $\mathbb{T}_r$). With $L = \mathbb{T}_r^2$ and the alternating pairing $\langle x, y\rangle = \lambda(x_1y_2 - x_2y_1)$ (perfect, with $\mathbb{T}_r$ self-adjoint), $L[\wp] = I^2$ has basis $(u, 0)$, $(0, u)$ with $u = (\varpi^r, 0)$, $d = 2$, and $\Delta = \lambda(u^2)^2 = \varpi^{2r} = \eta^2$: the shape of Lemma lem:hecke and of Step 2 of the proof of Theorem thm:quant. Finally, when $\eta = 0$ the

inequality is empty, and if moreover $L \simeq \mathbb{T}^r$, then $I \subseteq \wp$ gives $I \cdot I = 0$, so the pairing vanishes on $L[\wp] = I^r$ ($\langle \sum a_i e_i, \sum b_j e_j \rangle = \sum \langle b_j a_i e_i, e_j \rangle = 0$) and $\Delta = 0$: the hypothesis $\Delta \neq 0$ excludes this case.

The paper's proof. The paper works over a discrete valuation ring with finite residue field and counts orders; the book's lengths make sense over any discrete valuation ring (Convention 3.1(f)), and the lemma is proved in that form in Chapter 20. In the converse inclusion "if $y \perp L[\wp]$ then $\dots$ $ty = 0$, and $y \in L[I]$ because $I = \mathcal{O}t$", the single element t suffices because $I = \mathcal{O}t$ (Proposition 3.110(iii)); Proposition 3.113(iii) uses every $s \in I$ instead. The directness of $L[\wp] + L[I]$ rests, in the paper as in Proposition 3.113(ii), on the nonzero scalar $\pi(t) \in \wp + I$.

3.12 Exercises

The exercises are graded from routine to harder; those marked "check the paper" verify a sentence of the paper with the tools of this chapter.

Exercise 3.119. Compute $\mathbb{Z}/m \otimes \mathbb{Z}/n$, $\mathbb{Q} \otimes \mathbb{Z}/n$, $\mathbb{Z}_\ell \otimes \mathbb{Z}/n$, $\mathbb{Q}_\ell/\mathbb{Z}_\ell \otimes \mathbb{Z}/n$, $\mathrm{Hom}(\mathbb{Z}/m, \mathbb{Z}/n)$ and $\mathrm{Hom}_{\mathbb{Z}_\ell}(\mathbb{Q}_\ell/\mathbb{Z}_\ell, \mathbb{Z}/\ell^k)$. Show that $\mathrm{Hom}(\mathbb{Z}/2, -)$ is not right exact and $- \otimes \mathbb{Z}/2$ is not left exact on $0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \mathbb{Z}/2 \to 0$. (Answers: $\mathbb{Z}/\gcd(m,n)$, 0, $\mathbb{Z}/\ell^{v_\ell(n)}$, 0, $\mathbb{Z}/\gcd(m,n)$, 0.)

Exercise 3.120 (check the paper: Lemma lem:IV)**.** Let T be free of rank 2 over $\mathbb{Z}_3$ with an automorphism σ such that $\sigma^2 + \sigma + 1 = 0$. Using that $\mathbb{Z}_3[\zeta_3]$ is a discrete valuation ring with uniformiser $1 - \zeta_3$ (Chapter 6), show that T is free of rank one over $\mathbb{Z}_3[X]/(X^2 + X + 1) \simeq \mathbb{Z}_3[\zeta_3]$ (Proposition 3.46(iii)), that $T/3T \simeq \mathbb{Z}_3[\zeta_3]/(1-\zeta_3)^2$ (note $(1-\zeta_3)^2 = -3\zeta_3$), and that the vectors of $T/3T$ fixed by σ form a line. Deduce that in a suitable basis $\sigma = \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}$.

Exercise 3.121. Show that Fitting ideals are multiplicative in short exact sequences of finite $\mathbb{Z}_\ell$-modules. Show that they are not over $\mathbb{Z}[x]$, using $0 \to R/(2,x) \to R/(4,x) \to R/(2,x) \to 0$ (Proposition 3.71(vi)). Over $R = k[x]/(x^2)$, show that $\mathrm{Fitt}(k) = (x)$ and that $0 \to k \to R \to k \to 0$ and $0 \to k \to k \oplus k \to k \to 0$ both satisfy $\mathrm{Fitt}(M) = \mathrm{Fitt}(M')\,\mathrm{Fitt}(M'')$ (both sides are 0). Compute Fitt and Ann of $\mathbb{Z}[x]/(2,x)$ and of its square.

Exercise 3.122 (higher Fitting ideals)**.** For M with n generators and a relation matrix A, let $\mathrm{Fitt}_i(M)$ be the ideal generated by the $(n-i) \times (n-i)$ minors of A, with $\mathrm{Fitt}_i(M) = R$ for $i \geq n$ (so Fitt_0 is the Fitting ideal of Definition 3.69). (a) Show that $\mathrm{Fitt}_i(M)$ does not depend on the presentation, and that $\mathrm{Fitt}_0(M) \subseteq \mathrm{Fitt}_1(M) \subseteq \cdots$. (Hint: the proof of Lemma 3.70 works for minors of size $n - i$; for an added generator, column operations turn the new relation matrix into $\mathrm{diag}(A, 1)$, and Laplace expansion puts its minors of size $n + 1 - i$ in the ideal of minors of size $n - i$ of A.) (b) Over a discrete valuation ring let $M = \bigoplus_{j=1}^{s} \mathcal{O}/\varpi^{a_j}$ with $1 \leq a_1 \leq \cdots \leq a_s$. Show that $\mathrm{Fitt}_i(M) = \varpi^{a_1 + \cdots + a_{s-i}}\mathcal{O}$ for $i < s$ and $\mathrm{Fitt}_i(M) = \mathcal{O}$ for $i \geq s$. Deduce that the Fitt_i determine a torsion M up to isomorphism, that $\dim_k M[\varpi]$ is the least i with $\mathrm{Fitt}_i(M) = \mathcal{O}$, and that M is cyclic iff $\mathrm{Fitt}_1(M) = \mathcal{O}$. (c) Over $\mathbb{Z}_\ell$, compute Fitt_0 and Fitt_1 of $\mathbb{Z}/\ell^2$ and of $(\mathbb{Z}/\ell)^2$. (Answers: $\mathrm{Fitt}_0 = \ell^2\mathbb{Z}_\ell$ for both; $\mathrm{Fitt}_1 = \mathbb{Z}_\ell$ and $\ell\mathbb{Z}_\ell$. So Fitt_1 separates the two modules that Theorem 3.72(iv) shows Fitt_0 cannot.)

Exercise 3.123 (cofinitely generated modules)**.** (a) Show that a quotient of a divisible module is divisible. Let W be cofinitely generated of corank r and $F \subseteq W$ a finite submodule; show that W/F is cofinitely generated of corank r, and that $W/F \simeq (\mathbb{Q}_\ell/\mathbb{Z}_\ell)^r$ if W is divisible.

(Hint: dualising, $(W/F)^*$ is the kernel of $W^* \to F^*$, a submodule of finite index of W^*; use Theorem 3.77.) (b) Show that multiplication by ℓ identifies $\mathbb{Q}_\ell/\mathbb{Z}_\ell/(\mathbb{Q}_\ell/\mathbb{Z}_\ell)[\ell]$ with $\mathbb{Q}_\ell/\mathbb{Z}_\ell$, and that under this identification the dual of the quotient map $\mathbb{Q}_\ell/\mathbb{Z}_\ell \to \mathbb{Q}_\ell/\mathbb{Z}_\ell/(\mathbb{Q}_\ell/\mathbb{Z}_\ell)[\ell]$ is the inclusion $\ell\mathbb{Z}_\ell \subseteq \mathbb{Z}_\ell$. (c) For $W = \mathbb{Q}_\ell/\mathbb{Z}_\ell \oplus \mathbb{Z}/\ell$ compute $W[\ell]$, the divisible part $\bigcap_k \ell^k W$, the corank and W^*. (Answers: $(\mathbb{Z}/\ell)^2$; $\mathbb{Q}_\ell/\mathbb{Z}_\ell \oplus 0$; 1; $\mathbb{Z}_\ell \oplus \mathbb{Z}/\ell$.)

Exercise 3.124 (the Gram determinant of a sublattice of finite index; the prime 2)**.** (a) Let $L' \subseteq L$ be lattices of the same rank over $\mathcal{O}$, B the matrix whose rows are the coordinates of a basis of L' in a basis of L, and G the Gram matrix of a pairing on L. Show that the Gram matrix of L' is BGB^{T}, so that $v(\Delta_{L'}) = v(\Delta_L) + 2\,\mathrm{length}(L/L')$ (Theorem 3.50). (b) On $L = \mathbb{Z}_2^2$ with the perfect alternating pairing $\langle x, y\rangle = x_1y_2 - x_2y_1$, let $L' = \mathbb{Z}_2 e_1 \oplus \mathbb{Z}_2 \cdot 2e_2$, of index 2. Compute the Gram determinant and the ideal of values of L', and check (a) and Proposition 3.87(ii). (Answer: $\Delta = 4$, values $2\mathbb{Z}_2$.) (c) Show that $\frac{1}{2}\langle\ ,\ \rangle$ is perfect on L' but not $\mathbb{Z}_2$-valued on L, while for ℓ odd $\frac{1}{2}\langle\ ,\ \rangle$ is perfect on $\mathbb{Z}_\ell^2$. Deduce that passing between $\hat{\delta}_!$ and the cup product, which differ by the factor $\frac{1}{2}$ (Paper link 3.90), preserves perfectness and Gram determinants up to units only for ℓ odd: over $\mathbb{Z}_2$ the factor $\frac{1}{2}$ changes the ideal of values by 2 and the Gram determinant of a rank-two lattice by 4.

Exercise 3.125 (the saturation of $\wp L$; reduction modulo ϖ)**.** In the setting of Proposition 3.113: (a) Show that $\mathrm{sat}(\wp L) = L[I]$ and $\mathrm{sat}(IL) = L[\wp]$. (Hint: Proposition 3.89(ii), Proposition 3.83(ii) and Proposition 3.113(iii).) (b) Let $\mathbb{T}_r$ ($r \geq 1$, Example 3.112) act on $L = \mathcal{O}^2$ coordinatewise, with the standard pairing and $\pi(a, b) = a$. Show that $\wp L = 0 \oplus \varpi^r\mathcal{O}$ is not saturated, that $L[I] = 0 \oplus \mathcal{O}$, and that the map $L[\wp]/\varpi L[\wp] \to (L/\varpi L)[\wp]$, injective for every L because $L[\wp]$ is saturated (Proposition 3.49(i)(d)), is not surjective here: the reduction of $L[\wp]$ is a line, while $\wp$ kills all of $L/\varpi L = k^2$.

Exercise 3.126 (check the paper: Lemma lem:crit)**.** Let $\mathbb{T}$ act on S with a perfect pairing $S \times \mathbb{T} \to \mathbb{Z}$ as in Proposition 3.91, and let $\mathfrak{a}$, $\mathfrak{b}$ be ideals as in its part (iii). Show that $S/(S[\mathfrak{a}] \oplus S[\mathfrak{b}])$ has the same order as $\mathbb{T}/(\mathfrak{a} + \mathfrak{b})$. Work it out for $\mathbb{T} = \mathbb{Z}[x]/(x^2 - 4)$ acting on $S = \mathbb{T}^\vee$, $\mathfrak{a} = (x - 2)$, $\mathfrak{b} = (x + 2)$ (answer: 4), and interpret the result as a congruence modulo 4 between two "eigenforms", the elements of $S[\mathfrak{a}]$ and $S[\mathfrak{b}]$. Show that the rank hypothesis in (iii) cannot be dropped. (Hint: $\mathfrak{a} = \mathfrak{b} = 0$.)

Exercise 3.127 (three eigenvalues)**.** Let $\mathbb{T} = \mathbb{Z}[x]/(x(x - 2)(x - 6))$, which embeds in $\mathbb{Z}^3$ by $x \mapsto (0, 2, 6)$, and $\pi(x) = 0$. (a) Show that $\wp = (x)$, $I = \mathrm{Ann}_{\mathbb{T}}(\wp) = \mathbb{Z}\,(x-2)(x-6)$ and $\eta = 12\mathbb{Z}$, and that 12 is the denominator of the idempotent $e_\pi = (x - 2)(x - 6)/12$ (Proposition 3.110(iii); its proof works verbatim over $\mathbb{Z}$, Paper link 3.111). (b) Show that $\mathbb{T} \otimes \mathbb{Z}_2$ is local and that $\mathbb{T} \otimes \mathbb{Z}_3 = \mathbb{T}_{\mathfrak{m}} \times \mathbb{T}_{\mathfrak{m}'}$ with $\mathfrak{m} = (3, x)$ and $\mathfrak{m}' = (3, x - 2)$, with idempotent $e_{\mathfrak{m}'} = x(x - 6)/(-8)$. Compute the congruence ideal in $\mathbb{T}_{\mathfrak{m}}$ and in $\mathbb{T} \otimes \mathbb{Z}_2$, and compare with Proposition 3.110(v). (Answers: $3\mathbb{Z}_3$ and $4\mathbb{Z}_2$.) (c) 2-adically, the eigenvalue 0 is congruent to 2 and to 6 only modulo 2, yet $v_2(\eta) = 2$. Explain this: η is generated by $\pi((x - 2)(x - 6)) = (0 - 2)(0 - 6)$, and it measures the congruence of π with the whole complementary factor $\mathbb{Q} \times \mathbb{Q}$ of $\mathbb{T} \otimes \mathbb{Q}$, not with each other eigenvalue separately (Proposition 3.53).

Exercise 3.128 (check the paper: the congruence ideal is computed in $\mathbb{T}_{\mathfrak{m}}$)**.** For $\mathbb{T} \otimes \mathbb{Z}_\ell = \prod_{\mathfrak{m}'} \mathbb{T}_{\mathfrak{m}'}$ and π factoring through $\mathbb{T}_{\mathfrak{m}}$, show that $\mathrm{Ann}(\ker \pi) = \mathrm{Ann}_{\mathbb{T}_{\mathfrak{m}}}(\wp_{\mathfrak{m}}) \times 0$. Do the other local factors lie in the annihilator or in the kernel? Compute both for $\mathbb{T} = \mathbb{Z}[x]/(x^2 - 4)$, $\ell = 3$ and $\pi(x) = 2$.

Exercise 3.129 (check the paper: non-semisimple U_p in Lemma lem:old)**.** For the operator U of Example 3.105(a) compute the characteristic polynomial, show that v_e is a cyclic vector, and find an eigenvector for each eigenvalue; deduce that for $e \geq 3$ the algebra generated by U is not reduced. With Chapter 13: carry this out for the full Hecke algebra of level 88 acting on the span of $f_{11}(z)$, $f_{11}(2z)$, $f_{11}(4z)$, $f_{11}(8z)$, where $a_2(f_{11}) = -2$, and check with PARI that U_2 has characteristic polynomial $X^7(X^2 + 2X + 2)$ on all of $S_2(\Gamma_0(88))$.

Exercise 3.130 (Gorenstein algebras and faithful modules)**.** (a) Show that $\mathbb{T}_r$ ($r \geq 1$) and $\mathbb{Z}_\ell[x]/(x^2)$ are local and Gorenstein, and that $\mathbb{T}_3^\flat = \{(a,b,c) \in \mathbb{Z}_\ell^3 : a \equiv b \equiv c \bmod \ell\}$ is local and not, by computing the socles of their reductions modulo ℓ. For which monic f is $\mathbb{Z}_\ell[x]/(f)$ local? (Answer: when $f \bmod \ell$ is a power of one irreducible polynomial.) (b) Let $\mathbb{T}$ be a local finite free $\mathbb{Z}_\ell$-algebra. Show that there is a *faithful* $\mathbb{T}$-module L, free of finite rank over $\mathbb{Z}_\ell$, with a perfect pairing for which $\mathbb{T}$ is self-adjoint and with $\dim_{k_\mathbb{T}} L/\mathfrak{m}L = 1$, if and only if $\mathbb{T}$ is Gorenstein. (Hint: by Nakayama L is cyclic, so $L \simeq \mathbb{T}/\operatorname{Ann}_\mathbb{T}(L) = \mathbb{T}$, and Theorem 3.116 applies with $d = 1$; conversely take $L = \mathbb{T}$ with the pairing of Proposition 3.115(i).) (c) Show that faithfulness cannot be dropped in (b): $\mathbb{T}_3^\flat$ acting on $L = \mathbb{Z}_\ell$ through $\pi(a,b,c) = a$, with the pairing xy, has $\dim L/\mathfrak{m}L = 1$. Show that $\mathbb{T}_3^\flat$ acts faithfully on $L = \mathbb{Z}_\ell^3$ coordinatewise, self-adjointly for the standard pairing, with $\dim_{\mathbb{F}_\ell} L/\mathfrak{m}L = 3$, so that hypothesis (b) of Theorem 3.116 fails ($\operatorname{rank} L = 3 \neq 3 \operatorname{rank} \mathbb{T}_3^\flat$).

3.13 Notes and references

The material of Sections 1 to 4 is standard and follows Atiyah and Macdonald [7, Chapters 1 to 3, 6, 7] and Dummit and Foote [58, Chapters 10 and 12]; Lang [109, Chapters III and X] and Eisenbud [62, Chapters 2 to 4] give the same results in greater generality. Our proof of right exactness of the tensor product through the adjunction is the one in Atiyah and Macdonald; the snake and five lemmas are in Weibel [205, Section 1.3], whose numbering Chapter 16 uses. Hilbert's basis theorem, the equivalence of finite length with "Noetherian and Artinian", and the characterisation of discrete valuation rings as integrally closed one-dimensional Noetherian local domains are cited, not proved. Every chapter, section or theorem number quoted from a book in this chapter (Atiyah-Macdonald, Dummit-Foote, Lang, Eisenbud, Weibel, Jacobson, Matsumura, Serre, Neukirch-Schmidt-Wingberg, Rubin, Mazur, Darmon-Diamond-Taylor) is a pointer, not a verified citation.

The Smith normal form over a principal ideal domain (Theorem 3.41) is proved here by induction on the number of prime factors, which avoids the Euclidean hypothesis; Jacobson [88, Section 3.7] gives the same argument. The structure theorem and stacked bases are in Dummit and Foote [58, Section 12.1]. Saturated submodules are the pure submodules of Bourbaki. The congruence module of a decomposition (Proposition 3.53) and the duality of Proposition 3.91 are the commutative algebra behind Hida's congruence modules [82] and Ribet's treatment of the congruence number [159]; Agashe, Ribet and Stein [3] use them for the modular degree.

Discrete valuation rings and the ring $\mathbb{Z}_\ell$ follow Serre [174, Chapters I and II]; the analytic theory is Chapter 7. Baer's criterion and the injectivity of divisible modules are in Weibel [205, Section 2.3]. Pontryagin duality for finite groups is in Serre [172, Chapter VI, Section 1]; for compact and discrete $\mathbb{Z}_\ell$-modules see Neukirch, Schmidt and Wingberg [143, Chapter I, Section 1] and Rubin [167, Appendix B]. Our proof of the structure of cofinitely generated modules (Theorem 3.77(iii)) is algebraic and avoids compactness.

Fitting ideals were introduced by Fitting in 1936. We follow Northcott [144] and Eisenbud [62, Section 20.2]; the proof of Lemma 3.70 is the standard one through the ideal of determinants of all tuples of relations. Mazur and Wiles [127, Appendix] use Fitting ideals of $\mathbb{Z}_\ell$-modules as here, and the Tamagawa factors of the paper are Fitting ideals because of Fontaine and Perrin-Riou [69, I.4.2.2], as recalled by Diamond, Flach and Guo [49].

Sections 10 and 11 follow Darmon, Diamond and Taylor [38, Section 4], especially the discussion of congruence modules leading to their Lemma 4.17, whose inequality half is the paper's Lemma lem:ddt417; the toy algebras $\mathbb{T}_r$ and $\mathbb{T}_3^\flat$ are the standard examples of a congruence and of a non-Gorenstein algebra. The structure of Artinian rings is [7, Chapter 8], and idempotent lifting over complete rings is in Eisenbud [62, Section 7.5]; our Newton iteration $e \mapsto 3e^2 - 2e^3$ needs no Hensel lemma. Gorenstein rings are treated in Matsumura [124, Chapter 18] and Eisenbud [62, Chapter 21]; the socle criterion (Proposition 3.115(ii)) is the form used for Hecke algebras by Mazur [125, Chapter II, Section 15] and Tilouine [199]. Theorem 3.116 abstracts Mazur's argument that multiplicity one gives freeness and the Gorenstein property; the geometric input for the Hecke algebra is Chapter 14, with Ribet and Stein [163].

Rigour. Everything in this chapter is proved except: Hilbert's basis theorem; "finite length iff Noetherian and Artinian"; criterion (e) for discrete valuation rings; completions in general (Artin-Rees); localisation of Hom; topological Nakayama (sketched); Pontryagin duality for general compact modules; the Pfaffian identity in general rank and the symplectic normal form (sketched); Jordan-Chevalley; complete intersections are Gorenstein, and Wiles's numerical criterion; and the identification of $\mathbb{T}_{\mathfrak{m}}$ with an $\mathfrak{m}$-adic completion. The computations quoted (Smith forms, 11-adic roots and idempotents, characteristic polynomials of the shift operator and of U_2 at level 88, the Pfaffian in rank 4) were checked with PARI/GP [148].

Chapter 4

Representations of finite groups and the mod ℓ world

The objects of the paper are representations: $V = V_\ell E$, $T = T_\ell E$, $\rho = \rho_{E,\ell}$ and its reduction $\bar\rho$ are representations of the absolute Galois group $G_{\mathbb{Q}}$, and the adjoint $A_f = \operatorname{ad}^0 V$ is built from them by linear algebra. Most of what the paper needs about them is not Galois theory at all but the representation theory of a group, often a finite one, over a field of characteristic 0 or ℓ, or over $\mathbb{Z}_\ell$. This chapter supplies that theory: irreducibility and absolute irreducibility, Schur's lemma, Maschke's theorem and its failure in characteristic ℓ, the theorem of Brauer and Nesbitt, induced representations and Clifford theory for a subgroup of index 2, twisting, the adjoint representation and its trace form, the representations of $\mathrm{GL}_2(\mathbb{F}_3)$ and of its subgroups on $\mathbb{F}_3^2$ and $\mathbb{F}_9^2$, the action of finite cyclic groups and of unipotent elements on rank-two spaces and lattices, and lattices over a discrete valuation ring. Every statement is proved for an abstract group; the Galois input (continuity, Chebotarev, complex conjugation, the cyclotomic character) is added in Chapter 5 and Chapter 11, which cite the results proved here. The chapter uses Chapter 1 for the group theory of $\mathrm{GL}_2(\mathbb{F}_3)$, Chapter 2 for finite fields, and Chapter 3 for modules over a discrete valuation ring and the Jordan-Hölder theorem.

Core results at a glance

Throughout, G is a group, k a field, $\bar k$ an algebraic closure, R a commutative ring, and representations are finite-dimensional (Convention 4.1). $\mathcal{O}$ is a discrete valuation ring with uniformiser ϖ, fraction field K and residue field $\mathcal{O}/\varpi$. The matrices $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, $\sigma = \operatorname{diag}(1,-1)$, $w = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, $u = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$, $a = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ and the subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$ are the standard models of Chapter 1; $\mathbb{F}_9 = \mathbb{F}_3[i]$.

4.1 Conventions. Matrices act on column vectors on the left; $V^\vee = \operatorname{Hom}_k(V,k)$ with $(g\lambda)(v) = \lambda(g^{-1}v)$ (the symbol * is reserved for Pontryagin duals); $\operatorname{End}(V) = V \otimes V^\vee$ with $g \cdot x = \rho(g) x \rho(g)^{-1}$, $\operatorname{ad}^0 V$ its trace-zero part, with basis $e = e_1 \otimes e_2^\vee$, $h = e_1 \otimes e_1^\vee - e_2 \otimes e_2^\vee$, $f = e_2 \otimes e_1^\vee$ when $\dim V = 2$; a character is a homomorphism $\chi\colon G \to R^\times$, $M(\chi) = M \otimes_R R(\chi)$; tr_V is the trace function. Convention 4.1.

4.2 Representations (definition): a homomorphism $\rho\colon G \to \mathrm{GL}(V)$, V a finite-dimensional k-vector space, equivalently a $k[G]$-module of finite dimension; matrix representations are

isomorphic iff conjugate by one $P \in \mathrm{GL}_n(k)$; examples: characters, permutation and regular representations, the standard representation of $H \leq \mathrm{GL}_2(k)$, inflation. Definition 4.2.

4.3 Constructions (definition): subrepresentations, quotients, $V \oplus W$, $V \otimes W$, $V^\vee$, $\mathrm{Hom}_k(V, W)$ with $(g\phi)(v) = g\phi(g^{-1}v)$, invariants V^G, $\det \rho$. Definition 4.3.

4.4 Basic facts. $\mathrm{tr}(g \mid V^\vee) = \mathrm{tr}(g^{-1} \mid V)$, $\mathrm{tr}(g \mid V \otimes W) = \mathrm{tr}(g \mid V)\,\mathrm{tr}(g \mid W)$, $\det(V \otimes \chi) = \chi^n \det V$; $V^{\vee\vee} \simeq V$, $(V \otimes W)^\vee \simeq V^\vee \otimes W^\vee$; if $\dim V = 2$ (or V free of rank 2 over R), $v \mapsto \det[v \mid -]$ is a G-isomorphism $V \simeq V^\vee \otimes \det$, so $V^\vee \simeq V \otimes \det^{-1}$. *(proved here)* Proposition 4.4.

4.5 Hom_G as invariants. $V^\vee \otimes W \to \mathrm{Hom}(V, W)$, $\lambda \otimes w \mapsto \lambda(\cdot)w$, is a G-isomorphism (also for free modules of finite rank over R), and $\mathrm{Hom}_G(V, W) = \mathrm{Hom}(V, W)^G = (V^\vee \otimes W)^G$; for a character χ, $(\mathrm{End}(V) \otimes \chi)^G = \mathrm{Hom}_G(V, V \otimes \chi)$. *(proved here)* Proposition 4.5.

4.6 Extension of scalars. For a field extension K/k: (i) $\mathrm{Hom}_{K[G]}(V_K, W_K) = K \otimes_k \mathrm{Hom}_{k[G]}(V, W)$ and $(V_K)^G = K \otimes_k V^G$; (ii) if V, W are irreducible and $V_K \simeq W_K$ then $V \simeq W$; (iii) if V_K is irreducible and $W_K \simeq V_K$ then $W \simeq V$; (iv) (Noether-Deuring) $V_K \simeq W_K$ implies $V \simeq W$ for all V, W. *(proved here for (i) to (iii); (iv) stated; reference)* Proposition 4.7.

4.7 Irreducible, indecomposable (definition): $V \neq 0$ with no subrepresentations but 0, V; not a direct sum of two nonzero subrepresentations; for $\dim V = 2$, irreducible iff no line is stable. Definition 4.9.

4.8 Schur's lemma. For irreducible V, W over any field: (i) a G-map $V \to W$ is 0 or an isomorphism, and $\mathrm{End}_G(V)$ is a division algebra; (ii) if $k = \bar{k}$, $\mathrm{End}_G(V) = k$ and $\dim \mathrm{Hom}_G(V, W) \in \{0, 1\}$, with 1 iff $V \simeq W$; (iii) the same over any k for absolutely irreducible V, W; (iv) the centre acts on an absolutely irreducible V by scalars, absolutely irreducible representations of abelian groups are one-dimensional, and $\mathrm{End}_G(V)$ is a field for V irreducible and G abelian. *(proved here)* Theorem 4.10.

4.9 Absolutely irreducible (definition): $V_{\bar{k}}$ is irreducible. Definition 4.11.

4.10 Criteria for absolute irreducibility. (i) V is absolutely irreducible iff $k[G] \to \mathrm{End}_k(V)$ is surjective, and then V_K is irreducible for every extension K/k; (ii) absolutely irreducible implies irreducible with $\mathrm{End}_G(V) = k$; (iii) for $\dim V = 2$: iff no line of $\bar{k}^2$ is stable; (iv) over any field, an irreducible V is absolutely irreducible iff $\mathrm{End}_G(V) = k$. *(proved here)* Proposition 4.12.

4.11 Distinct eigenvalues. If some $g \in G$ acts on V with $\dim V$ distinct eigenvalues in k, every G-stable subspace of $V_{\bar{k}}$ is defined over k; so V is irreducible iff it is absolutely irreducible. In particular this holds for $\dim V = 2$, $\mathrm{char}\, k \neq 2$, if some $c \in G$ has $\rho(c)^2 = 1$, $\det \rho(c) = -1$. *(proved here)* Proposition 4.13.

4.12 C_4 on $\mathbb{F}_3^2$. $C_4 = \langle J \rangle$ acts irreducibly but not absolutely irreducibly on $\mathbb{F}_3^2$, with $\mathrm{End}_{C_4}(\mathbb{F}_3^2) = \mathbb{F}_3[J] \simeq \mathbb{F}_9$; over $\mathbb{F}_9$, $\mathbb{F}_9^2 = \mathbb{F}_9 v \oplus \mathbb{F}_9 \bar{v}$ with $v = (1, i)^t$, $\bar{v} = (1, -i)^t$, $Jv = iv$, $J\bar{v} = -i\bar{v}$: the sum $\psi \oplus \psi^{-1}$, $\psi(J) = i$ of order 4. *(proved here)* Example 4.14.

4.13 Semisimple (definition): a sum of irreducible subrepresentations. Definition 4.16.

4.14 Semisimple modules. For finite-dimensional V and any G: V is a sum of irreducibles iff a direct sum of irreducibles iff every subrepresentation has a stable complement; subrepresentations and quotients of semisimple representations are semisimple; $V = \bigoplus_S V_S$ with $V_S \simeq S^{m_S}$, and $m_S = \dim \mathrm{Hom}_G(S, V)$ if S is absolutely irreducible. *(proved here)* Proposition 4.17.

4.15 Maschke. (i) If G is finite and $\mathrm{char}\, k \nmid \#G$, every representation of G over k is semisimple. (ii) If $\#G \in R^\times$ and M is an $R[G]$-module, $e_G = \frac{1}{\#G}\sum_g g$ is an idempotent with $e_G M = M^G$, $M = M^G \oplus (1 - e_G)M$, and $(M/IM)^G = M^G/IM^G$ for every ideal I: invariants commute with reduction. *(proved here)* Theorem 4.18.

4.16 Failures of semisimplicity. $\mathrm{U} = \langle u \rangle$ on $\mathbb{F}_3^2$ is indecomposable and not semisimple; $\mathbb{F}_p[C_p]$ is uniserial; $\mathbb{Z}$ acting on $\mathbb{Q}_\ell^2$ through $\left(\begin{smallmatrix} 1 & n' \\ 0 & 1 \end{smallmatrix}\right)$, $n' \neq 0$, is not semisimple; $\mathrm{B}(\mathbb{F}_3)$ on $\mathbb{F}_3^2$ has $\mathrm{End}_{\mathrm{B}} = \mathbb{F}_3$ but is reducible. *(proved here)* Example 4.20.

4.17 Jordan-Hölder. A module of finite length over any ring (here $k[G]$ or $\mathcal{O}[G]$) has a composition series, and the composition factors with multiplicity, and the length, do not depend on the series. *(stated; reference: proved in Chapter 3)* Theorem 4.21.

4.18 Semisimplification (definition): $V^{ss} = \bigoplus_i M_i/M_{i-1}$ for a composition series (M_i). Definition 4.22.

4.19 Properties of V^{ss}. (i) V^{ss} is well defined, $V^{ss} \simeq V$ iff V is semisimple, and $(\cdot)^{ss}$ is additive in short exact sequences; (ii) $\det(X - g \mid V) = \det(X - g \mid V^{ss})$; (iii) over a perfect k, $(V^{ss})_K \simeq (V_K)^{ss}$ for algebraic K/k. *(proved here for (i), (ii); (iii) stated; reference)* Proposition 4.23.

4.20 Extensions of two characters. Let $\dim V = 2$ with a stable line L on which G acts by η_1, and η_2 on V/L, $\rho = \left(\begin{smallmatrix} \eta_1 & b \\ 0 & \eta_2 \end{smallmatrix}\right)$. (i) V is semisimple iff $V \simeq \eta_1 \oplus \eta_2$ iff V has a second stable line iff $b(g) = c(\eta_2(g) - \eta_1(g))$ for some $c \in k$; (ii) if V is not semisimple, L is its only stable line, and an isomorphism of two such extensions matches the sub-characters and the quotient characters; (iii) if $\eta_1 \neq \eta_2$ and V is semisimple, V has exactly two stable lines. *(proved here)* Proposition 4.24.

4.21 Absolute irreducibility in dimension 2. (i) If $\rho(G)$ is abelian, ρ is absolutely reducible; (ii) if $\rho(G)$ is finite of order prime to $\mathrm{char}\, k$ and ρ is absolutely reducible, then $\rho(G)$ is abelian; so a finite non-abelian subgroup of $\mathrm{GL}_2(k)$ of order prime to $\mathrm{char}\, k$ acts absolutely irreducibly; (iii) if $\mathrm{Res}_H \rho$ is absolutely irreducible, so is ρ; (iv) Q_8, $\mathrm{SL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$, $\mathrm{GL}_2(\mathbb{F}_3)$ and $N_s(\mathbb{F}_3)$ act absolutely irreducibly on $\mathbb{F}_3^2$; C_4, $C_{ns}(\mathbb{F}_3)$, $\mathrm{B}(\mathbb{F}_3)$ do not. *(proved here)* Proposition 4.26.

4.22 Trace function (definition): $\mathrm{tr}_V(g) = \mathrm{tr}\, \rho(g)$, a class function (the "character" of Riley-Hobson-Bence). Definition 4.28.

4.23 Orthogonality. G finite, $k = \mathbb{C}$, $\langle \phi, \psi \rangle = \frac{1}{\#G}\sum_g \phi(g)\overline{\psi(g)}$: (i) for irreducible V, W, $\langle \mathrm{tr}_V, \mathrm{tr}_W \rangle$ is 1 if $V \simeq W$ and 0 otherwise; (ii) $\dim \mathrm{Hom}_G(V, W) = \langle \mathrm{tr}_W, \mathrm{tr}_V \rangle$, V is irreducible iff $\langle \mathrm{tr}_V, \mathrm{tr}_V \rangle = 1$, and the trace function determines V; (iii) the irreducible trace functions are an orthonormal basis of the class functions, their number is the number of conjugacy classes, and $\sum_i (\dim V_i)^2 = \#G$; (iv) $\dim V_i$ divides $\#G$. *(proved here for (i) to (iii); (iv) stated; reference)* Theorem 4.29.

4.24 Traces in characteristic 0. If $\operatorname{char} k = 0$, two semisimple representations of any group with the same trace function are isomorphic. *(proved here)* Corollary 4.30.

4.25 D_4 and Q_8. They have the same character table and are not isomorphic; the two-dimensional representation of D_4 is defined over $\mathbb{Q}$ and reduces modulo 3 to the standard representation of $N_s(\mathbb{F}_3)$. *(proved here)* Example 4.31.

4.26 Traces fail in characteristic p. Over $\mathbb{F}_3$, $\mathbf{1}^{\oplus 3}$ and $\operatorname{sgn}^{\oplus 3}$ of C_2 have the same traces and are not isomorphic; traces suffice in dimension $< p$. *(proved here)* Example 4.32.

4.27 Density theorem (Jacobson, Burnside). For pairwise non-isomorphic irreducible $S_1, \dots, S_r$ with $D_i = \operatorname{End}_G(S_i)$: (a) the image of $k[G] \to \prod_i \operatorname{End}_k(S_i)$ is $\prod_i \operatorname{End}_{D_i}(S_i)$; (b) if $k = \bar{k}$, it is $\prod_i \operatorname{End}_k(S_i)$. *(proved here)* Theorem 4.34.

4.28 Brauer-Nesbitt. If $\det(X - \rho_1(g)) = \det(X - \rho_2(g))$ in $k[X]$ for all $g \in G$ (any group, any field), then $V_1^{ss} \simeq V_2^{ss}$. Equal traces suffice if $\operatorname{char} k = 0$ or $\dim V_1, \dim V_2 < \operatorname{char} k$. *(proved here)* Theorem 4.35.

4.29 Consequences. (i) In dimension 2, equal traces and equal determinants give $V_1^{ss} \simeq V_2^{ss}$; (ii) if V_1 is over k, V_2 over $k' \supseteq k$, they have the same characteristic polynomials, and $V_1 \otimes_k k'$ is irreducible, then $V_2 \simeq V_1 \otimes_k k'$; this fails when V_1 is only irreducible over k. *(proved here)* Corollary 4.36.

4.30 Induction (definition): $\operatorname{Ind}_H^G W = k[G] \otimes_{k[H]} W$, $\operatorname{Res}_H^G V$. Definition 4.38.

4.31 Induced representations. For $G = \bigsqcup_i s_i H$ of finite index m: $\operatorname{Ind} W = \bigoplus_i s_i \otimes W$, $\dim \operatorname{Ind} W = m \dim W$, $\operatorname{tr}(g \mid \operatorname{Ind} W) = \sum_{s_i^{-1} g s_i \in H} \operatorname{tr}(s_i^{-1} g s_i \mid W)$; for $[G : H] = 2$, $s \notin H$ and a character ψ of H: $h \mapsto \operatorname{diag}(\psi(h), \psi^s(h))$, $s \mapsto \left(\begin{smallmatrix} 0 & \psi(s^2) \\ 1 & 0 \end{smallmatrix}\right)$, with $\psi^s(h) = \psi(s^{-1}hs)$. *(proved here)* Proposition 4.39.

4.32 Frobenius reciprocity. $\operatorname{Hom}_G(\operatorname{Ind}_H^G W, V) \simeq \operatorname{Hom}_H(W, \operatorname{Res}_H V)$, and for finite index $\operatorname{Hom}_G(V, \operatorname{Ind}_H^G W) \simeq \operatorname{Hom}_H(\operatorname{Res}_H V, W)$, over a field or a commutative ring. *(proved here)* Theorem 4.40.

4.33 Projection formula. $\operatorname{Ind}(W \otimes \operatorname{Res} U) \simeq \operatorname{Ind} W \otimes U$; so $\operatorname{Ind} W \otimes \chi \simeq \operatorname{Ind} W$ if $\chi|_H = 1$; $\operatorname{Ind}_H^G \mathbf{1} = k[G/H]$, $\simeq \mathbf{1} \oplus \chi_H$ for index 2 and $\operatorname{char} k \neq 2$; transitivity, additivity, extension of scalars. *(proved here)* Proposition 4.41.

4.34 Mackey. (a) $\operatorname{Res}_K \operatorname{Ind}_H^G W \simeq \bigoplus_{s \in K \backslash G / H} \operatorname{Ind}_{K \cap sHs^{-1}}^K W^s$; (b) in characteristic 0, G finite, $\operatorname{Ind} W$ is irreducible iff W is irreducible and W^s, W have no common constituent on $sHs^{-1} \cap H$ for $s \notin H$; (c) for $[G : H] = 2$, any characteristic, W absolutely irreducible: $\operatorname{Res}_H \operatorname{Ind} W \simeq W \oplus W^s$, and $\operatorname{Ind} W$ is absolutely irreducible iff $W_{\bar{k}} \not\simeq W^s_{\bar{k}}$. *(stated; reference for (a); proof sketched here for (b); proved here for (c))* Theorem 4.42.

4.35 Clifford. For $N \trianglelefteq G$ of finite index and V irreducible over any field, $\operatorname{Res}_N V$ is semisimple, its constituents form one G-orbit and have equal multiplicities. *(proved here)* Theorem 4.43.

4.36 Clifford theory for index 2. $[G : H] = 2$, χ_H the character with kernel H, $\operatorname{char} k \neq 2$, V absolutely irreducible of dimension n. Either (A) $\operatorname{Res}_H V$ is absolutely irreducible and $V \not\simeq V \otimes \chi_H$; or (B) $n = 2d$, $\operatorname{Res}_H V_{\bar{k}} \simeq W \oplus W^s$ with $W \not\simeq W^s$ absolutely irreducible,

$V_{\bar{k}} \simeq \operatorname{Ind}_H^G W$, and $V \simeq V \otimes \chi_H$ over k, with $\operatorname{Hom}_G(V, V \otimes \chi_H)$ a line spanned by an isomorphism of trace 0 with eigenspaces W, W^s. For $n = 2$: (B) iff $V_{\bar{k}} \simeq \operatorname{Ind} \psi$ with $\psi^s \neq \psi$. *(proved here)* Theorem 4.44.

4.37 Dihedral representations. For $\rho\colon G \to \mathrm{GL}_2(k)$ absolutely irreducible, $\operatorname{char} k \neq 2$, with finite projective image P: P is not cyclic; P is dihedral (including V_4) iff $\rho \simeq \rho \otimes \chi$ for a character of order 2 iff $\rho_{\bar{k}}$ is induced from an index-two subgroup; the characters $\chi \neq 1$ with $\rho \simeq \rho \otimes \chi$ correspond to the cyclic subgroups of index 2 of P (one if $\#P \geq 6$, three if $P \simeq V_4$). *(proved here)* Proposition 4.46.

4.38 Twisting. $\operatorname{tr}(\rho \otimes \chi) = \chi \operatorname{tr} \rho$, $\det(\rho \otimes \chi) = \chi^n \det \rho$; (absolute) irreducibility and Hom_G are unchanged; $\operatorname{End}(V \otimes \chi) = \operatorname{End}(V)$ and $\operatorname{ad}^0(V \otimes \chi) = \operatorname{ad}^0 V$; $V \simeq V \otimes \chi$ forces $\chi^n = 1$. *(proved here)* Proposition 4.48.

4.39 Trace-zero lemma. If $\phi\colon V \to V \otimes \chi$ is a G-map then $(1 - \chi(g)) \operatorname{tr} \phi = 0$ for all g; so $\operatorname{tr} \phi = 0$ if $\chi \neq 1$ (over a field) or if $1 - \chi(g) \in R^\times$ for some g. *(proved here)* Lemma 4.49.

4.40 Adjoint (definition): $\operatorname{End}(V)$ with $g \cdot x = \rho(g) x \rho(g)^{-1}$, and $\operatorname{ad}^0 V = \ker \operatorname{tr}$. Definition 4.51.

4.41 The adjoint. (i) $\operatorname{End}(V) = k \oplus \operatorname{ad}^0 V$ if $n \in k^\times$; (ii) $\operatorname{Ad} \rho(g)$ has eigenvalues λ_i/λ_j, and on $\operatorname{ad}^0 V$ for $n = 2$: $\lambda_1/\lambda_2, 1, \lambda_2/\lambda_1$; (iii) in the basis e, h, f: $\operatorname{Ad} \operatorname{diag}(x, y) = \operatorname{diag}(x/y, 1, y/x)$; for $t = \left(\begin{smallmatrix} 1 & n' \\ 0 & 1 \end{smallmatrix}\right)$, $(t-1)e = 0$, $(t-1)h = -2n'e$, $(t-1)f = n'h - n'^2 e$; for $F = \left(\begin{smallmatrix} \varepsilon q & c' \\ 0 & \varepsilon \end{smallmatrix}\right)$, $FeF^{-1} = qe$, $FhF^{-1} = h - 2c'\varepsilon^{-1}e$, $FfF^{-1} = q^{-1}f + c'\varepsilon^{-1}q^{-1}h - c'^2\varepsilon^{-2}q^{-1}e$. *(proved here)* Proposition 4.52.

4.42 Invariants of twisted adjoints. (i) $(\operatorname{End} V \otimes \chi)^G = \operatorname{Hom}_G(V, V \otimes \chi)$; (ii) if $n \in R^\times$, $(\operatorname{ad}^0 V \otimes \chi)^G$ is its trace-zero part; (iii) if χ (over a local R: its reduction) is nontrivial, every such map has trace 0; (iv) for V absolutely irreducible, $(\operatorname{ad}^0 V)^G = 0$, and for $\chi \neq 1$, $(\operatorname{ad}^0 V \otimes \chi)^G \neq 0$ iff $V \simeq V \otimes \chi$, and then it is a line. *(proved here)* Proposition 4.54.

4.43 Symmetric square. For $\dim V = 2$, $\Xi(xy)(v) = \omega(v, x)y + \omega(v, y)x$ is a G-map $\operatorname{Sym}^2 V \otimes \det^{-1} \to \operatorname{ad}^0 V$ with $\Xi(e_1^2) = -2e$, $\Xi(e_1 e_2) = h$, $\Xi(e_2^2) = 2f$, an isomorphism iff 2 is invertible (index 4 over $\mathbb{Z}$); so $\operatorname{ad}^0 V \simeq \operatorname{Sym}^2 V \otimes \det^{-1}$; for $V = V_\ell E$, $\operatorname{Sym}^2(V^\vee) \simeq \operatorname{ad}^0 V(-1)$ and $L_p(\operatorname{Sym}^2 f, s) = L_p(A_f, s - 1)$. *(proved here)* Proposition 4.56.

4.44 Trace form. $B(x, y) = \operatorname{tr}(xy)$ on $\operatorname{End}_R(T)$ is G-invariant and perfect; on $\operatorname{ad}^0 T$ ($n = 2$) its Gram matrix in e, h, f has determinant -2, so for ℓ odd $\operatorname{ad}^0 T \simeq (\operatorname{ad}^0 T)^\vee$ and $\operatorname{Hom}_{\mathbb{Z}_\ell}(\operatorname{ad}^0 T, \mathbb{Z}_\ell(\chi)) \simeq \operatorname{ad}^0 T(\chi)$; for $\ell = 2$ the index is 2. *(proved here)* Proposition 4.58.

4.45 The adjoint ignores twists, duals and homotheties. $\operatorname{ad}^0(V \otimes \chi) = \operatorname{ad}^0 V$; $x \mapsto -x^t$ is a G-isomorphism $\operatorname{ad}^0 V \simeq \operatorname{ad}^0(V^\vee)$; for lattices, $\operatorname{ad}^0(cL) = \operatorname{ad}^0 L$ and $\operatorname{ad}^0(L^\vee)$ corresponds to $\operatorname{ad}^0 L$. *(proved here)* Proposition 4.60.

4.46 The subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$ on $\mathbb{F}_3^2$. The table of irreducibility, absolute irreducibility, $\dim \operatorname{End}_H$, $\dim(\operatorname{ad}^0 \rho)^H$, $\dim \operatorname{Hom}_H(\rho, \rho \otimes \det)$, the twist $\rho \simeq \rho \otimes \det$, and projective images, for $\mathrm{GL}_2, \mathrm{SL}_2, N_{ns}, Q_8, N_s, C_{ns}, C_4, C_s, \mathrm{B}, \mathrm{U}$. *(proved here; checked by computer)* Proposition 4.62.

4.47 $N_s(\mathbb{F}_3)$ is induced over $\mathbb{F}_9$. The standard representation ρ of $N_s(\mathbb{F}_3)$ is absolutely irreducible; in the basis $v = (1, i)^t$, $\sigma v = (1, -i)^t$ of $\mathbb{F}_9^2$, $\rho(J) = \operatorname{diag}(i, -i)$ and $\rho(\sigma) = w$,

so $\rho \otimes \mathbb{F}_9 \simeq \mathrm{Ind}_{C_4}^{N_s} \psi$, $\psi(J) = i$; over $\mathbb{F}_3$, ρ is not induced from C_4; $\rho \simeq \rho \otimes \chi$ for the three characters with kernels C_4, C_s, $\{\pm 1, \pm w\}$, with intertwiners J, σ, w; $(\mathrm{ad}^0 \rho \otimes \det)^{N_s} = \mathbb{F}_3 J$. *(proved here)* Proposition 4.63.

4.48 $N_{ns}(\mathbb{F}_3)$**.** Its standard representation and its restriction to Q_8 are absolutely irreducible; $\rho \not\simeq \rho \otimes \det$ and $(\mathrm{ad}^0 \rho \otimes \det)^{N_{ns}} = 0$; $\rho \otimes \mathbb{F}_9 \simeq \mathrm{Ind}_{C_{ns}}^{N_{ns}} \theta$, $\theta(a) = 1 + i$, and $\rho \simeq \rho \otimes \chi$ only for the character with kernel $C_{ns}(\mathbb{F}_3)$. *(proved here)* Proposition 4.64.

4.49 $\mathrm{SL}_2(\mathbb{F}_3)$ **and** $\mathrm{GL}_2(\mathbb{F}_3)$**.** Their standard representations are absolutely irreducible; for $\mathrm{GL}_2(\mathbb{F}_3)$, $\rho \not\simeq \rho \otimes \det$ and $(\mathrm{ad}^0 \rho \otimes \det)^{\mathrm{GL}_2(\mathbb{F}_3)} = 0$; projective images A_4, S_4. *(proved here)* Proposition 4.65.

4.50 The three images. For H conjugate to $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ or $N_s(\mathbb{F}_3)$ and $H_1 = H \cap \mathrm{SL}_2(\mathbb{F}_3)$, equivalent: (a) H is conjugate to $N_s(\mathbb{F}_3)$; (b) $\mathrm{Res}_{H_1} \rho$ is not absolutely irreducible; (c) $\rho \simeq \rho \otimes \det$; (d) $(\mathrm{ad}^0 \rho \otimes \det)^H \neq 0$; (e) $\rho \otimes \mathbb{F}_9 \simeq \mathrm{Ind}_{H_1}^H \psi$ with ψ of order 4; (f) H_1 is abelian. Then $(\mathrm{ad}^0 \rho \otimes \det)^H$ is a line spanned by a trace-zero isomorphism; otherwise it is 0. *(proved here)* Theorem 4.66.

4.51 The letter σ**.** In Section 4.9 σ is the paper's element of order 3 and $\mathrm{diag}(1, -1)$ is h. Convention 4.68.

4.52 Unipotent elements. For $u \neq 1$ unipotent in $\mathrm{GL}_2(k)$ and $\xi \in k^\times \setminus \{1\}$: V^u is a line, $V^{\xi u} = 0$; if $\mathrm{char}\, k \neq 2$, $(\mathrm{ad}^0 V)^u = (\mathrm{ad}^0 V)^{\xi u} = k(u-1)$, a line; if $FuF^{-1} = u^q$ then F acts on it by q (and F^{-1} by q^{-1}). *(proved here)* Proposition 4.69.

4.53 Commutant lemma. If $x \in \mathrm{End}_k(V)$ has $\dim V$ distinct eigenvalues in $\bar{k}$, or $\dim V = 2$ and x is not scalar, its commutant is $k[x] \simeq k[X]/(\det(X - x))$; for $\dim V = 2$ and $\mathrm{char}\, k \neq 2$ its trace-zero part is the line $k(2x - \mathrm{tr}\, x)$; it is a field iff $\det(X - x)$ is irreducible. *(proved here)* Lemma 4.70.

4.54 Cyclic groups of order $2, 3, 4, 6$**.** An element $g \in \mathrm{SL}_2(K)$ of order $m \in \{3, 4, 6\}$, $\mathrm{char}\, K \nmid m$, has characteristic polynomial Φ_m; order 2 means $g = -1$. Fixed spaces on V and $\mathrm{ad}^0 V$ (table), the invariant line of $\mathrm{ad}^0 V$ spanned by $g - g^{-1}$, and an F with $FgF^{-1} = g^r$ acts on it by ± 1 according as $r \equiv \pm 1 \pmod m$. *(proved here)* Proposition 4.71.

4.55 Reduction of finite cyclic subgroups of $\mathrm{SL}_2(\mathbb{Z}_\ell)$**.** For g of order $m \in \{2, 3, 4, 6\}$: if $\ell \nmid m$, invariants on T and $\mathrm{ad}^0 T$ commute with reduction; if $\ell = 3$, $m = 3$, then $\bar{g}$ is a nontrivial unipotent, $(T/3T)^g$ is a line while $T^g = 0$, and $(\mathrm{ad}^0 T)^g = \mathbb{Z}_3(2g + 1)$ reduces onto $(\mathrm{ad}^0 T/3)^g$; for $m = 6, 4, 2$ and $\ell = 3$, $(T/3T)^g = 0$; the integral commutant is $\mathbb{Z}_\ell[g] \simeq \mathbb{Z}_\ell[X]/(\Phi_m)$. *(proved here; the freeness of T over $\mathbb{Z}_\ell[g]$ stated; reference)* Proposition 4.72.

4.56 Lattices (definition): finitely generated $\mathcal{O}$-submodules spanning V; homothety $L' = cL$. Definition 4.74.

4.57 Stable lattices. Any two lattices satisfy $\varpi^a L \subseteq L' \subseteq \varpi^{-b} L$; for finite G, $\sum_g \rho(g) L_0$ is stable; $\varpi^m L$, $L^\vee$, $L \otimes \mathcal{O}(\chi)$, $\mathrm{End}_{\mathcal{O}}(L)$, $\mathrm{ad}^0 L$ are stable, and $\mathrm{ad}^0 L/\varpi^m = \mathrm{ad}^0(L/\varpi^m L)$. *(proved here)* Proposition 4.75.

4.58 Reduction. $\det(X - \bar{\rho}_L(g))$ is the reduction of $\det(X - \rho(g))$; $\bar{\rho}_L^{ss}$ does not depend on L; if $\bar{\rho}_L$ is irreducible for one L, $\bar{\rho}_{L'} \simeq \bar{\rho}_L$ for all L'. *(proved here)* Proposition 4.76.

4.59 Homothety lemma. If $\bar\rho_L$ is irreducible, every G-stable lattice is $\varpi^m L$ for a unique $m \in \mathbb{Z}$. *(proved here)* Theorem 4.77.

4.60 Non-homothetic lattices. For the upper triangular group, $\mathbb{Z}_\ell e_1 \oplus \mathbb{Z}_\ell e_2$ and $\mathbb{Z}_\ell e_1 \oplus \ell\mathbb{Z}_\ell e_2$ are stable, not homothetic, with non-isomorphic reductions of equal semisimplification. *(proved here)* Example 4.79.

4.61 Ribet's lemma. Let K be finite over $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}$, G compact, and $\rho\colon G \to \mathrm{GL}_2(K)$ continuous and irreducible. If $\bar\rho^{ss} \simeq \eta_1 \oplus \eta_2$, some stable lattice reduces to a non-split extension with sub-character η_1 (and one with sub-character η_2). *(stated; reference)* Theorem 4.80.

4.62 Twisted self-isomorphisms modulo ϖ^m. If $T/\varpi T$ is absolutely irreducible, the module of G-maps $T/\varpi^m \to (T/\varpi^m)(\chi)$ is cyclic, its elements of exact order ϖ^m are isomorphisms, and the length of the invariants of $X = \mathrm{End}_{\mathcal{O}}(T)(\chi) \otimes K/\mathcal{O}$ is the largest h with $T/\varpi^h \simeq (T/\varpi^h)(\chi)$; the same for $\mathrm{ad}^0 T(\chi)$ if $n \in \mathcal{O}^\times$, $\bar\chi \neq 1$; $\chi^n \equiv 1 \pmod{\varpi^h}$; for $n = 2$, ℓ odd, $\chi(G) = \mathbb{Z}_\ell^\times$: $h = 0$ if $\ell \geq 5$, $h \leq 1$ if $\ell = 3$. *(proved here)* Proposition 4.81.

4.63 The mod ℓ dictionary. For $\bar\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{F}_\ell)$ continuous, ℓ odd, $\det\bar\rho = \bar\chi_\ell$: irreducible equals absolutely irreducible; for $\bar\rho$ irreducible, the hypothesis of Theorem thm:main fails iff $\bar\rho \simeq \bar\rho \otimes \chi_{\ell^*}$, iff $\bar\rho \otimes \overline{\mathbb{F}}_\ell$ is induced from $G_{\mathbb{Q}(\sqrt{\ell^*})}$ (for $\bar\rho$ reducible it always fails); Lemma lem:h0 concerns $\bar\rho \simeq \bar\rho \otimes \bar\chi_\ell$, possible only for $\ell = 3$. *(proved here from the cited Galois input)* Remark 4.83.

4.64 Dickson. For ℓ odd and $G \leq \mathrm{GL}_2(\mathbb{F}_\ell)$: if $\ell \mid \#G$, $G \supseteq \mathrm{SL}_2(\mathbb{F}_\ell)$ or G lies in a Borel subgroup; if $\ell \nmid \#G$, the image in $\mathrm{PGL}_2(\mathbb{F}_\ell)$ is cyclic, dihedral, or A_4, S_4, A_5. *(stated; reference)* Theorem 4.84.

Where the paper uses this chapter

- **Proposition prop:ns** (the image $N_s(\mathbb{F}_3)$): the three images and their determinant-one subgroups, Theorem 4.66; absolute irreducibility of Q_8 and $\mathrm{SL}_2(\mathbb{F}_3)$, Proposition 4.26; ψ of order 4 and $\bar\rho \otimes \mathbb{F}_9 \simeq \mathrm{Ind}\,\psi$, Example 4.14, Proposition 4.63, Theorem 4.40; $\bar\rho \simeq \bar\rho \otimes \chi_{-3}$, Proposition 4.41, Theorem 4.44, descended to $\mathbb{F}_3$ by Proposition 4.7; $H^0(\mathbb{Q}, \mathrm{ad}^0\,\bar\rho(1)) \neq 0$, Proposition 4.54.

- **Lemma lem:h0** (the term $h_\ell(E)$): H^0 of a twisted adjoint as trace-zero G-maps, Proposition 4.5, Proposition 4.54; the trace-zero lemma, Lemma 4.49; Schur, Theorem 4.10; cyclicity, isomorphisms modulo ℓ^k and the determinant bound, Proposition 4.81; Clifford theory for $\mathbb{Q}(\sqrt{-3})$, Theorem 4.44.

- **Lemma lem:IV, Remark rem:types, Lemma lem:euler, Proposition prop:ns-structure**: unipotent and minus-unipotent elements, Proposition 4.69; the commutant and its trace-zero line, Lemma 4.70; elements of order $2, 3, 4, 6$ and the action of Frobenius on the invariant line, Proposition 4.71; reduction modulo 3, Proposition 4.72; Maschke over $\mathbb{Z}_\ell$, Theorem 4.18.

- **Lemma lem:old** (oldforms): Brauer-Nesbitt over a common finite field, Theorem 4.35, Corollary 4.36; absolute irreducibility from complex conjugation, Proposition 4.13; the unique stable line of a non-split extension, Proposition 4.24.

- **Section 4.2** (the theorem of Diamond, Flach and Guo) **and Lemma lem:fpr**: $A = \mathrm{ad}^0 T$, $T^D = \mathrm{Hom}(A, \mathbb{Z}_\ell(1)) \simeq A(1)$ by the trace form, Proposition 4.58; the adjoint of $M_{f,\lambda} \simeq T_\ell E(-1)$ is $\mathrm{ad}^0 T$, Proposition 4.60; the homothety lemma as an alternative route, Theorem 4.77.

- **Lemma lem:tamfactor** (the Tamagawa factor at a multiplicative prime): the basis e, h, f and the action of t and of the Frobenius matrix, Proposition 4.52; the invariants of a unipotent, Proposition 4.69; the shape $\left(\begin{smallmatrix} \chi_\ell \varepsilon & \varepsilon\kappa \\ 0 & \varepsilon \end{smallmatrix}\right)$, Proposition 4.24.

- **Section 1.1 and the Introduction**: $A_f = \mathrm{ad}^0 V$, the eigenvalues $\alpha/\beta, 1, \beta/\alpha$, Proposition 4.52; $\mathrm{ad}^0 \simeq \mathrm{Sym}^2 \otimes \det^{-1}$ and $L_p(\mathrm{Sym}^2 f, s) = L_p(A_f, s-1)$, Proposition 4.56.

- **Proofs of Theorems thm:main and thm:quant, Lemma lem:euler (types I_n^*, I_0^*)**: $\mathrm{ad}^0 T$ is unchanged by twists, Proposition 4.48, Proposition 4.60.

- **The hypothesis of Theorem thm:main, Proposition prop:Sf, DDT Theorem 3.15**: absolute irreducibility on $G_{\mathbb{Q}(\sqrt{\ell^*})}$, Definition 4.11, Theorem 4.44, Proposition 4.46, Remark 4.83.

- **Conjecture conj:euler, Remark rem:ns, Section sec:anomaly** (the image 3Ns and $h_3(E) = 1$): Proposition 4.63, Theorem 4.66, Proposition 4.81.

4.1 Representations over a field

This section fixes the language: representations, the linear constructions on them, and the behaviour of spaces of G-maps under extension of the field of scalars. In the paper these are used silently everywhere. Three uses are explicit: the identification of H^0 of a twisted adjoint with a space of G-maps in Lemma lem:h0 (Proposition 4.5), the descent from $\mathbb{F}_9$ to $\mathbb{F}_3$ of the isomorphism $\bar\rho \simeq \bar\rho \otimes \chi_{-3}$ in Proposition prop:ns, and the phrase "over a common finite extension of $\mathbb{F}_\ell$" in Lemma lem:old (Proposition 4.7). The words "irreducible" and "absolutely irreducible" and Schur's lemma, defined and proved in Section 4.2, are used here by forward reference; there is no circularity, since Proposition 4.7(ii) uses only Theorem 4.10(i), whose proof uses nothing from this section.

Convention 4.1. The following conventions hold in this chapter.

(C1) *Representations.* G is a group (finite only where this is said), k a field and R a commutative ring. A representation of G over k is a homomorphism $\rho\colon G \to \mathrm{GL}(V)$ with V a *finite-dimensional* k-vector space; over R, V is a free R-module of finite rank. Matrices act on column vectors on the left (as in Chapter 1). A *G-map* (intertwiner) is a $k[G]$-linear map; $\mathrm{Hom}_G(V, W)$ is the space of G-maps and $V \simeq W$ means isomorphic as representations. We often write gv for $\rho(g)v$.

(C2) *Duals.* The linear dual is $V^\vee = \mathrm{Hom}_k(V, k)$ with $(g\lambda)(v) = \lambda(g^{-1}v)$; in the dual basis $(e_i^\vee)$, g acts by the matrix $\rho(g^{-1})^t$. The symbol * is reserved for Pontryagin duals (convention B-C4 of Appendix B).

(C3) *Adjoints.* $\mathrm{End}(V) = \mathrm{End}_k(V)$ is a representation by $g \cdot x = \rho(g) x \rho(g)^{-1}$; written $\mathrm{Ad}\, V$ when the action is to be stressed. $\mathrm{ad}^0 V$ is its subspace of trace zero (the paper's notation;

the superscript 0 is part of the symbol). $\operatorname{Sym}^2 V$ is the symmetric square. The matrix units are $E_{ij} = e_i \otimes e_j^\vee$, and for $\dim V = 2$ the basis of $\mathrm{ad}^0 V$ is the paper's

$$e = E_{12} = e_1 \otimes e_2^\vee, \qquad h = E_{11} - E_{22}, \qquad f = E_{21} = e_2 \otimes e_1^\vee,$$
$$e = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \qquad h = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \qquad f = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

(C4) *Characters and twists.* A character of G with values in R is a homomorphism $\chi\colon G \to R^\times$. $R(\chi)$ is R with G acting through χ, and $M(\chi) = M \otimes_R R(\chi)$, also written $M \otimes \chi$ or $\rho \otimes \chi$. The trace function of V is written tr_V, never χ_V, so that the letter χ is free for characters such as χ_{-3} and the cyclotomic χ_ℓ.

(C5) *Fields.* $\bar{k}$ is an algebraic closure of k, and $V_K = K \otimes_k V$ for an extension K/k. $\mathbb{F}_9 = \mathbb{F}_3[i]$ with $i^2 = -1$ (Chapter 2).

(C6) *Standard models.* $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, $\sigma = \mathrm{diag}(1, -1)$, $w = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, $u = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$, $a = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$, and the subgroups C_s, N_s, C_{ns}, N_{ns}, Q_8, $C_4 = \langle J \rangle$, B, U $= \langle u \rangle$ of $\mathrm{GL}_2(\mathbb{F}_3)$ are the standard models of Chapter 1. Thus $J = m_{-i}$ is multiplication by $-i$ on $\mathbb{F}_9 = \mathbb{F}_3 \oplus \mathbb{F}_3 i$, $a = m_{1+i}$, $a^2 = J$, $w = \sigma J$, $N_s(\mathbb{F}_3) = \langle J, \sigma \rangle$, $N_{ns}(\mathbb{F}_3) = \langle a, \sigma \rangle$, and $\psi\colon C_4 \to \mathbb{F}_9^\times$ is the character $\psi(J) = i$.

(C7) *Lattices.* $\mathcal{O}$ is a discrete valuation ring with uniformiser ϖ, fraction field K and residue field $\mathcal{O}/\varpi$; in the paper $\mathcal{O} = \mathbb{Z}_\ell$ and $\varpi = \ell$. A lattice in a K-vector space of dimension n is a finitely generated $\mathcal{O}$-submodule that spans it; it is free of rank n (Chapter 3).

(C8) *No Galois groups.* This chapter never uses Frobenius elements. Where the paper's Frobenius appears it is an abstract element F with $FgF^{-1} = g^q$ for g in an inertia image, which is the relation satisfied by the *arithmetic* Frobenius (convention B-C2); the geometric Frobenius F^{-1} has the inverse eigenvalues. The letter q is then the paper's bad prime.

(C9) *Typography.* Double names take plain hyphens: Brauer-Nesbitt, Jordan-Hölder.

Definition 4.2 (Representations)**.** A *representation* of G over k is a homomorphism $\rho\colon G \to \mathrm{GL}(V)$, V a finite-dimensional k-vector space; equivalently, a left $k[G]$-module structure on V, where $k[G]$ is the group algebra (finite sums $\sum_g a_g g$). Its *degree* is $n = \dim V$; it is *faithful* if $\ker \rho = 1$. A basis of V turns ρ into a homomorphism $G \to \mathrm{GL}_n(k)$, and two such matrix representations ρ_1, ρ_2 are isomorphic iff there is one $P \in \mathrm{GL}_n(k)$ with $\rho_2(g) = P\rho_1(g)P^{-1}$ for all g (the matrix of an isomorphism). Examples:

(a) the trivial representation $\mathbf{1}$ ($V = k$, $g \mapsto 1$);

(b) one-dimensional representations, which are the characters $\chi\colon G \to k^\times$; they factor through the abelianisation G^{ab};

(c) the permutation representation $k[X]$ of a G-set X (basis X, g permuting it), and the regular representation $k[G]$;

(d) the *standard representation* of a subgroup $H \leq \mathrm{GL}_2(k)$ on k^2 (the inclusion);

(e) inflation: if $\pi\colon G \to G'$ is a homomorphism and ρ' a representation of G', then $\rho' \circ \pi$ is one of G. A representation of a finite quotient of a profinite group is thus one of the group (Chapter 5).

The representations of Riley-Hobson-Bence [165] are the case $k = \mathbb{C}$, G finite.

The two descriptions in Definition 4.2 are used side by side. The homomorphism ρ is what one computes with (matrices, traces, eigenvalues). The module language is what makes general theorems available: subrepresentations, quotients, composition series and G-maps are submodules, quotient modules, composition series and module maps over the ring $k[G]$, so the results of Chapter 3 apply without change. A small example already shows the phenomenon that organises Section 4.3. Let S_3 permute the coordinates of k^3. The line $D = k(1,1,1)^t$ and the plane $P = \{x : x_1 + x_2 + x_3 = 0\}$ are stable. If $\operatorname{char} k \neq 3$, then $D \cap P = 0$ (the vector $(c,c,c)^t$ lies in P iff $3c = 0$), and $k^3 = D \oplus P$ by counting dimensions. If $\operatorname{char} k = 3$, then $(1,1,1)^t \in P$, so $D \subset P$ and this decomposition is lost; we return to the example after Maschke's theorem.

Definition 4.3 (Constructions)**.** Let V, W be representations of G over k. A *subrepresentation* is a G-stable subspace $U \subseteq V$, and V/U is the quotient representation. G acts on $V \oplus W$ componentwise and on $V \otimes W$ by $g(v \otimes w) = gv \otimes gw$; on $V^\vee$ as in (C2); on $\operatorname{Hom}_k(V,W)$ by $(g\phi)(v) = g\,\phi(g^{-1}v)$. The *invariants* are $V^G = \{v : gv = v \text{ for all } g\}$, and $\det\rho\colon G \to k^\times$ is the character $g \mapsto \det\rho(g)$, the representation on $\wedge^n V$. The same definitions apply to free modules of finite rank over R.

Proposition 4.4. *Let V, W be representations of G over k, $n = \dim V$, χ a character.*

(i) $\operatorname{tr}(g \mid V \oplus W) = \operatorname{tr}(g \mid V) + \operatorname{tr}(g \mid W)$, $\operatorname{tr}(g \mid V \otimes W) = \operatorname{tr}(g \mid V)\operatorname{tr}(g \mid W)$, $\operatorname{tr}(g \mid V^\vee) = \operatorname{tr}(g^{-1} \mid V)$ *and* $\det(V \otimes \chi) = \chi^n \det V$.

(ii) The canonical maps $V \to V^{\vee\vee}$ and $V^\vee \otimes W^\vee \to (V \otimes W)^\vee$, $\lambda \otimes \mu \mapsto (v \otimes w \mapsto \lambda(v)\mu(w))$, are G-isomorphisms.

(iii) If $n = 2$ (or V is free of rank 2 over R), let $\omega(x,y) = \det[x\,|\,y]$. Then $\omega(gx,gy) = \det(g)\omega(x,y)$, and $v \mapsto \omega(v,-)$ is a G-isomorphism $V \to V^\vee \otimes \det$. Hence $V^\vee \simeq V \otimes \det^{-1}$.

Proof. (i) The first is clear in a basis adapted to $V \oplus W$; the second holds because the matrix of g on $V \otimes W$ in the basis $e_i \otimes f_j$ is the Kronecker product of the two matrices, whose trace is the product of the traces; the third because g acts on $V^\vee$ by $\rho(g^{-1})^t$; the fourth because $\det(\chi(g)\rho(g)) = \chi(g)^n \det\rho(g)$. (ii) Both maps are isomorphisms of vector spaces (compare bases). For the first, $v \mapsto (\lambda \mapsto \lambda(v))$, and $(g \cdot \mathrm{ev}_v)(\lambda) = \mathrm{ev}_v(g^{-1}\lambda) = (g^{-1}\lambda)(v) = \lambda(gv)$, so $g \cdot \mathrm{ev}_v = \mathrm{ev}_{gv}$. For the second, write Λ for the image of $\lambda \otimes \mu$, the form $v \otimes w \mapsto \lambda(v)\mu(w)$. The image of $g(\lambda \otimes \mu) = g\lambda \otimes g\mu$ is the form $v \otimes w \mapsto (g\lambda)(v)\,(g\mu)(w) = \lambda(g^{-1}v)\mu(g^{-1}w)$, while by (C2) for the representation $V \otimes W$,

$$(g\Lambda)(v \otimes w) = \Lambda(g^{-1}(v \otimes w)) = \Lambda(g^{-1}v \otimes g^{-1}w) = \lambda(g^{-1}v)\mu(g^{-1}w).$$

The two forms agree on pure tensors, which span $V \otimes W$, so the map is equivariant. It is bijective because it sends the basis $e_i^\vee \otimes f_j^\vee$ to the basis of $(V \otimes W)^\vee$ dual to $(e_i \otimes f_j)$. (iii) $\omega(gx,gy) = \det(\rho(g)[x\,|\,y]) = \det(g)\omega(x,y)$. Put $\Psi(v) = \omega(v,-)$. As ω is a perfect pairing ($\omega(e_1,e_2) = 1$), Ψ is an isomorphism of vector spaces (or of free R-modules). For $y \in V$,

$$(g \cdot \Psi(v))(y) = \Psi(v)(g^{-1}y) = \omega(v, g^{-1}y) = \det(g)^{-1}\omega(gv, y),$$

so $\Psi(gv) = \det(g)\,(g \cdot \Psi(v))$, which says that Ψ is G-equivariant from V to $V^\vee \otimes \det$.

In coordinates, $\Psi(e_1) = \omega(e_1, -) = e_2^\vee$ and $\Psi(e_2) = \omega(e_2, -) = -e_1^\vee$, so the matrix of Ψ from the basis (e_1, e_2) to $(e_1^\vee, e_2^\vee)$ is $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right) = J^{-1}$, and the equivariance of Ψ becomes the matrix identity

$$\rho(g^{-1})^t = \det(g)^{-1}\, J\rho(g)J^{-1}, \qquad J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},$$

which for $\rho(g) = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ says that both sides equal $\frac{1}{ad-bc}\left(\begin{smallmatrix} d & -c \\ -b & a \end{smallmatrix}\right)$. So a two-dimensional representation and its dual differ only by the twist by the determinant; for $V_\ell E$, whose determinant is the cyclotomic character, this is used in Proposition 4.56(iii). □

Proposition 4.5 (G-maps as invariants)**.** *For representations V, W over k (or free R-modules of finite rank with a G-action), the map*

$$\Theta\colon V^\vee \otimes W \to \operatorname{Hom}(V, W), \qquad \lambda \otimes w \mapsto (v \mapsto \lambda(v)w)$$

is a G-isomorphism, and $\operatorname{Hom}_G(V, W) = \operatorname{Hom}(V, W)^G = (V^\vee \otimes W)^G$. In particular $\operatorname{End}(V)^G = \operatorname{End}_G(V)$, and for a character χ, $(\operatorname{End}(V) \otimes \chi)^G = \operatorname{Hom}_G(V, V \otimes \chi)$, the space of $\phi \in \operatorname{End}(V)$ with $\phi\rho(g) = \chi(g)\rho(g)\phi$ for all g.

Proof. Θ sends $e_i^\vee \otimes f_j$ to the matrix unit mapping e_i to f_j, so it is bijective. It is equivariant: $\Theta(g\lambda \otimes gw)(v) = \lambda(g^{-1}v)\, gw = g(\Theta(\lambda \otimes w)(g^{-1}v)) = (g \cdot \Theta(\lambda \otimes w))(v)$. A linear map ϕ is fixed by G iff $g\phi g^{-1} = \phi$ for all g, that is, iff ϕ is a G-map. For the last statement, $\operatorname{Hom}(V, V \otimes \chi)$ is $\operatorname{End}(V)$ with g acting by $\phi \mapsto \chi(g)\rho(g)\phi\rho(g)^{-1}$, that is, $\operatorname{End}(V) \otimes \chi$; it is fixed iff $\phi\rho(g) = \chi(g)\rho(g)\phi$. □

In the paper 4.6. In the proof of Lemma lem:h0, the sentence "The ℓ^k-torsion of $H^0(\mathbb{Q}, W^D)$ is $H^0(\mathbb{Q}, \mathrm{ad}^0(T/\ell^k)(1))$, the group of trace-zero $G_\mathbb{Q}$-maps $T/\ell^k \to (T/\ell^k)(1)$" is Proposition 4.5 for the free $\mathbb{Z}/\ell^k$-module T/ℓ^k and $\chi = \chi_\ell \bmod \ell^k$, together with Proposition 4.75(iii) for $W^D[\ell^k] = \mathrm{ad}^0(T/\ell^k)(1)$. In Lemma lem:tamfactor the basis $e = e_1 \otimes e_2^\vee$ of $\mathrm{ad}^0 T$ is the image under Θ of a vector of $V^\vee \otimes V$, as in (C3).

Proposition 4.7 (Extension of scalars)**.** *Let K/k be a field extension and V, W representations of G over k.*

(i) $\operatorname{Hom}_{K[G]}(V_K, W_K) = K \otimes_k \operatorname{Hom}_{k[G]}(V, W)$ *inside* $\operatorname{Hom}_K(V_K, W_K) = K \otimes_k \operatorname{Hom}_k(V, W)$. *In particular the two spaces of G-maps have the same dimension, and $(V_K)^G = K \otimes_k V^G$.*

(ii) If V and W are irreducible (Definition 4.9) and $V_K \simeq W_K$, then $V \simeq W$.

(iii) If V_K is irreducible (for instance if V is absolutely irreducible, Proposition 4.12) and $W_K \simeq V_K$, then $W \simeq V$.

(iv) (Noether-Deuring) If $V_K \simeq W_K$, then $V \simeq W$, for arbitrary V, W.

Proof. (i) Being a G-map is a system of linear equations, with coefficients in k, on the entries of a matrix, and the point is that such a system has, over K, exactly the solutions obtained from those over k by extending scalars. Precisely, for $g \in G$ let $\delta_g\colon \operatorname{Hom}_k(V, W) \to \operatorname{Hom}_k(V, W)$ be $\phi \mapsto \rho_W(g)\phi - \phi\rho_V(g)$; then $\operatorname{Hom}_{k[G]}(V, W) = \bigcap_g \ker \delta_g$. As $\operatorname{Hom}_k(V, W)$ is finite-dimensional, the descending chain of finite intersections stabilises, so there are $g_1, \dots, g_r$ with $\bigcap_g \ker \delta_g = \ker \delta$ for the single linear map $\delta = (\delta_{g_1}, \dots, \delta_{g_r})$. A linear map defined over k has the same rank over K (rank is the size of a nonvanishing minor of its matrix), so $\ker(\delta \otimes K) = K \otimes \ker \delta$. Hence

$$\textstyle\bigcap_g \ker(\delta_g \otimes K) \subseteq \ker(\delta \otimes K) = K \otimes \bigcap_g \ker \delta_g \subseteq \bigcap_g \ker(\delta_g \otimes K),$$

and the left side is $\mathrm{Hom}_{K[G]}(V_K, W_K)$. The statement on invariants is the case $V = \mathbf{1}$. (ii) By (i), $\mathrm{Hom}_{k[G]}(V, W) \neq 0$; a nonzero G-map between irreducible representations is an isomorphism (Theorem 4.10(i)). (iii) If $U \subseteq W$ is a subrepresentation, U_K is a subrepresentation of $W_K \simeq V_K$, so $U_K \in \{0, W_K\}$ and $U \in \{0, W\}$; thus W is irreducible (it is nonzero). The same argument applied to V shows that V is irreducible, since V_K is. So (ii) applies. (iv) We do not prove this; see [37, Section 29]. It is not needed in the paper: wherever an isomorphism is descended, (ii) or (iii) applies. □

In the paper 4.8. Proposition prop:ns: $\bar\rho_{E,3} \otimes \mathbb{F}_9 \simeq \mathrm{Ind}\,\psi \simeq (\bar\rho_{E,3} \otimes \chi_{-3}) \otimes \mathbb{F}_9$, and both $\bar\rho_{E,3}$ and $\bar\rho_{E,3} \otimes \chi_{-3}$ are irreducible over $\mathbb{F}_3$; so (ii) gives $\bar\rho_{E,3} \simeq \bar\rho_{E,3} \otimes \chi_{-3}$ over $\mathbb{F}_3$ ("the isomorphism descending to $\mathbb{F}_3$"; the same sentence ends the proof of Lemma lem:h0, where it is (i)). Lemma lem:old: the residual representations of f and of h are compared over a common finite extension k' of $\mathbb{F}_\ell$; by (iii), an isomorphism there between $\bar\rho \otimes k'$ and $\bar\rho_h$ is all that is needed.

4.2 Irreducibility, Schur's lemma, absolute irreducibility

This section introduces irreducible and absolutely irreducible representations and proves Schur's lemma, the tool behind every step of the paper at which a nonzero map is concluded to be an isomorphism. Absolute irreducibility is the hypothesis of Theorem thm:main (on $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell^*}))$) and of DDT Theorem 3.15; before using Schur in the form $\mathrm{End} = k$ (Lemmas lem:h0 and lem:old) the paper passes from "irreducible" to "absolutely irreducible", and for $\bar\rho_{E,\ell}$ with ℓ odd this is automatic by the distinct-eigenvalue criterion (Proposition 4.13) applied to complex conjugation.

Definition 4.9. A representation $V \neq 0$ is *irreducible* (or simple) if its only subrepresentations are 0 and V, and *reducible* otherwise; it is *indecomposable* if it is not the direct sum of two nonzero subrepresentations. Irreducible implies indecomposable, not conversely (Example 4.20). If $\dim V = 2$, V is irreducible iff no line of V is G-stable, iff $\rho(G)$ lies in no Borel subgroup of $\mathrm{GL}(V)$ (the stabiliser of a line, Chapter 1). Examples: every one-dimensional representation is irreducible. The standard representations of $\mathrm{GL}_2(\mathbb{F}_3)$ and of $N_s(\mathbb{F}_3)$ on $\mathbb{F}_3^2$ are irreducible (they stabilise no line, Chapter 1), and so is that of $C_4 = \langle J \rangle$: a stable line would be spanned by an eigenvector of J, but the characteristic polynomial $X^2 + 1$ of J has no root in $\mathbb{F}_3$. The standard representations of $\mathrm{U} = \langle u \rangle$ and of $\mathrm{B}(\mathbb{F}_3)$ are reducible: they stabilise $\mathbb{F}_3 e_1$.

Theorem 4.10 (Schur's lemma)**.** *Let V, W be irreducible representations of a group G over a field k.*

(i) Every G-map $V \to W$ is 0 or an isomorphism. Hence $D = \mathrm{End}_G(V)$ is a division algebra, of finite dimension over k.

(ii) If k is algebraically closed, then $\mathrm{End}_G(V) = k$ (the scalars), and $\dim_k \mathrm{Hom}_G(V, W)$ is 1 if $V \simeq W$ and 0 otherwise.

(iii) The conclusions of (ii) hold over any k if V and W are absolutely irreducible (Definition 4.11).

(iv) If V is absolutely irreducible, every central element of G acts on V by a scalar; every absolutely irreducible representation of an abelian group is one-dimensional; and if G is abelian and V irreducible, $\mathrm{End}_G(V)$ is a field, equal to the image of $k[G]$ in $\mathrm{End}_k(V)$.

Proof. (i) If $\phi\colon V \to W$ is a G-map, $\ker\phi$ and $\operatorname{im}\phi$ are subrepresentations. If $\phi \neq 0$, then $\ker\phi \neq V$, so $\ker\phi = 0$, and $\operatorname{im}\phi \neq 0$, so $\operatorname{im}\phi = W$. A nonzero element of $\operatorname{End}_G(V)$ is therefore invertible, and its inverse is again a G-map. (ii) Let $\phi \in \operatorname{End}_G(V)$. As $V \neq 0$ is finite-dimensional and k algebraically closed, ϕ has an eigenvalue c; then $\phi - c$ is a G-map that is not injective, so $\phi - c = 0$ by (i). If $V \simeq W$ via α, then $\operatorname{Hom}_G(V,W) = \alpha \operatorname{End}_G(V) = k\alpha$; if not, $\operatorname{Hom}_G(V,W) = 0$ by (i). (iii) Now $V_{\bar k}$ and $W_{\bar k}$ are irreducible, so (ii) applies to them. By Proposition 4.7(i), $\dim_k \operatorname{End}_G(V) = \dim_{\bar k} \operatorname{End}_G(V_{\bar k}) = 1$, so $\operatorname{End}_G(V) = k$ (it contains the scalars); and $\dim_k \operatorname{Hom}_G(V,W) = \dim_{\bar k} \operatorname{Hom}_G(V_{\bar k}, W_{\bar k})$, which is 1 if $V_{\bar k} \simeq W_{\bar k}$ and 0 otherwise. It remains to see that $V_{\bar k} \simeq W_{\bar k}$ iff $V \simeq W$. One direction is clear. For the other, V and W are irreducible (a nonzero proper subrepresentation U of V would give the nonzero proper subrepresentation $U_{\bar k}$ of $V_{\bar k}$), so Proposition 4.7(ii) applies. (iv) A central z satisfies $\rho(z)\rho(g) = \rho(g)\rho(z)$ for all g, so $\rho(z) \in \operatorname{End}_G(V) = k$ by (iii). If G is abelian, every element is central, so every $\rho(g)$ is a scalar, every line is stable, and $\dim V = 1$. For the last statement let $A \subseteq \operatorname{End}_k(V)$ be the image of $k[G]$; it is a commutative subalgebra, and $\operatorname{End}_G(V)$ is the commutant of A, which contains A. For $0 \neq x \in A$, $\ker x$ is A-stable (A is commutative), hence G-stable and different from V, so $\ker x = 0$: A has no zero divisors, and a finite-dimensional commutative k-algebra without zero divisors is a field. Then V is an A-vector space whose A-subspaces are G-stable, so $\dim_A V = 1$, $V \simeq A$, and the commutant of A acting on itself by multiplication is A. □

Over a field that is not algebraically closed, $\operatorname{End}_G(V)$ can be a proper extension field of k (Example 4.14 below: $\mathbb{F}_9$ over $\mathbb{F}_3$), or even non-commutative. Let $\mathbb{H}$ be Hamilton's quaternions, and let $Q_8 = \{\pm 1, \pm\mathbf{i}, \pm\mathbf{j}, \pm\mathbf{k}\} \subset \mathbb{H}^\times$ act on $V = \mathbb{H} \simeq \mathbb{R}^4$ by left multiplication. As Q_8 spans $\mathbb{H}$ over $\mathbb{R}$, a Q_8-stable subspace is a left ideal of the division ring $\mathbb{H}$, hence 0 or $\mathbb{H}$: V is irreducible. A G-map is an $\mathbb{R}$-linear map ϕ commuting with left multiplication by all of $\mathbb{H}$, so $\phi(x) = \phi(x \cdot 1) = x\phi(1)$ is right multiplication by $\phi(1)$. Hence $\operatorname{End}_G(V) \simeq \mathbb{H}^{\mathrm{op}}$, a non-commutative division algebra of dimension 4 over $\mathbb{R}$, as (i) allows.

Definition 4.11. A representation V of G over k is *absolutely irreducible* if $V_{\bar k}$ is irreducible. It is *absolutely reducible* otherwise.

Proposition 4.12. *Let V be a representation of G over k, $n = \dim V$.*

(i) V is absolutely irreducible iff the map $k[G] \to \operatorname{End}_k(V)$ is surjective. If so, V_K is irreducible for every extension K/k.

(ii) An absolutely irreducible V is irreducible and $\operatorname{End}_G(V) = k$.

(iii) If $n = 2$, V is absolutely irreducible iff $\rho(G)$ stabilises no line of $\bar k^2$, iff $\rho(G)$ is not conjugate in $\mathrm{GL}_2(\bar k)$ into the upper triangular group.

(iv) If V is irreducible, V is absolutely irreducible iff $\operatorname{End}_G(V) = k$. This holds over every field k.

Proof. (i) Let $A \subseteq \operatorname{End}_k(V)$ be the image of $k[G]$. The image of $\bar k[G]$ in $\operatorname{End}_{\bar k}(V_{\bar k}) = \bar k \otimes_k \operatorname{End}_k(V)$ is $\bar k \otimes_k A$, of $\bar k$-dimension $\dim_k A$. If $V_{\bar k}$ is irreducible, the density theorem (Theorem 4.34(b), whose proof does not use this proposition) says that $\bar k \otimes_k A = \operatorname{End}(V_{\bar k})$, so $\dim_k A = n^2$ and $A = \operatorname{End}_k(V)$. Conversely, if $A = \operatorname{End}_k(V)$, then for every extension K/k the image of $K[G]$ is $\operatorname{End}_K(V_K)$, and a subspace stable under all of $\operatorname{End}_K(V_K)$ is 0 or V_K. (ii) If $U \subseteq V$ is a subrepresentation, $U_{\bar k}$ is one of $V_{\bar k}$; so V is irreducible. $\operatorname{End}_G(V) = k$ is Theorem 4.10(iii). (iii) A

nonzero proper subrepresentation of the two-dimensional $V_{\bar{k}}$ is a stable line; and $\rho(G)$ stabilises the line $\bar{k}e_1'$ iff it is upper triangular in a basis e_1', e_2'. (iv) One direction is (ii). Conversely let V be irreducible with $\mathrm{End}_G(V) = k$. The density theorem (Theorem 4.34(a), with $r = 1$) says that the image of $k[G]$ is $\mathrm{End}_{\mathrm{End}_G(V)}(V) = \mathrm{End}_k(V)$, and (i) applies. □

Proposition 4.13 (Distinct eigenvalues)**.** *Let V be a representation of any group G over k, $n = \dim V$, and suppose that some $g \in G$ (or some element of the image of $k[G]$) acts on V with n distinct eigenvalues $\lambda_1, \dots, \lambda_n \in k$. Then every G-stable subspace U of $V_{\bar{k}}$ is a sum of eigenlines of g, and $U = (U \cap V)_{\bar{k}}$ with $U \cap V$ a subrepresentation of V. In particular V is irreducible iff it is absolutely irreducible. This applies when $n = 2$, $\mathrm{char}\, k \neq 2$ and some $c \in G$ has $\rho(c)^2 = 1$, $\det \rho(c) = -1$: the eigenvalues of $\rho(c)$ are then 1 and -1, which are distinct.*

Proof. Let $v_1, \dots, v_n \in V$ be eigenvectors of g for $\lambda_1, \dots, \lambda_n$ (they exist over k because the λ_i lie in k); they form a basis of V and of $V_{\bar{k}}$. Let $u = \sum_i c_i v_i \in U$. Applying $\prod_{j \neq i}(g - \lambda_j)$, which preserves U, gives $c_i \prod_{j \neq i}(\lambda_i - \lambda_j) v_i \in U$, and the product is nonzero; so $c_i v_i \in U$ for every i. Hence U is spanned by the v_i it contains, $U = (U')_{\bar{k}}$ for the k-span U' of these v_i, and $U' = U \cap V$ is G-stable. If V is irreducible, $U \cap V \in \{0, V\}$, so $U \in \{0, V_{\bar{k}}\}$. The case $n = 2$: $\rho(c)^2 = 1$ gives eigenvalues in $\{\pm 1\}$, with product -1. □

Example 4.14 (C_4 on $\mathbb{F}_3^2$)**.** Let $C_4 = \langle J \rangle$, $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, act on $\mathbb{F}_3^2$. It is irreducible (Definition 4.9) but not absolutely irreducible: over $\mathbb{F}_9 = \mathbb{F}_3[i]$,

$$J\begin{pmatrix} 1 \\ i \end{pmatrix} = \begin{pmatrix} i \\ -1 \end{pmatrix} = i\begin{pmatrix} 1 \\ i \end{pmatrix}, \qquad J\begin{pmatrix} 1 \\ -i \end{pmatrix} = \begin{pmatrix} -i \\ -1 \end{pmatrix} = -i\begin{pmatrix} 1 \\ -i \end{pmatrix},$$

so with $v = (1, i)^t$ and $\bar{v} = (1, -i)^t$ we get $\mathbb{F}_9^2 = \mathbb{F}_9 v \oplus \mathbb{F}_9 \bar{v} \simeq \psi \oplus \psi^{-1}$, where $\psi(J) = i$ is a character of order 4 with values in $\mathbb{F}_9^\times$ (these are the two lines spanned by $(\mp i, 1)^t$ of Chapter 1). The vector $\bar{v}$ is obtained from v by the Frobenius $x \mapsto x^3$ of $\mathbb{F}_9$ on coordinates, and $\psi^{-1} = \psi^3$ is the Frobenius conjugate of ψ. The commutant is $\mathrm{End}_{C_4}(\mathbb{F}_3^2) = \mathbb{F}_3[J] \simeq \mathbb{F}_3[X]/(X^2 + 1) \simeq \mathbb{F}_9$ (Lemma 4.70), a field of dimension 2 over $\mathbb{F}_3$, as Proposition 4.12(iv) and Theorem 4.10(iv) predict. In contrast, $C_{ns}(\mathbb{F}_3) = \langle a \rangle \simeq \mathbb{F}_9^\times$ also acts irreducibly and not absolutely irreducibly, with commutant $\mathbb{F}_3[a] = \mathbb{F}_9$; and U fixes exactly one line of $\mathbb{F}_3^2$ and is not a direct sum of two lines (Example 4.20).

In the paper 4.15. The hypothesis of Theorem thm:main is that $\bar{\rho}_{E,\ell}$ is absolutely irreducible on $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell^*}))$; in DFG04 this is $\ell \notin S_f$. Example 4.14 is the reason why "absolutely" cannot be dropped: in the $N_s(\mathbb{F}_3)$ case the restriction to $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$ has image C_4, which is irreducible over $\mathbb{F}_3$ and splits as $\psi \oplus \psi^{-1}$ over $\mathbb{F}_9$ (Proposition prop:ns). In Lemmas lem:h0 and lem:old and in Proposition prop:Sf the paper deduces absolute irreducibility from irreducibility because complex conjugation has the distinct eigenvalues ± 1: this is the case $n = 2$ of Proposition 4.13, with c complex conjugation and $\det \bar{\rho}(c) = \bar{\chi}_\ell(c) = -1$ (Chapter 5).

4.3 Semisimplicity, Maschke's theorem, Jordan-Hölder

This section explains when a representation is a direct sum of irreducibles. Over a finite group of order prime to the characteristic it always is (Maschke); in characteristic dividing the order it need not be, and this failure is exactly what the paper's Lemma lem:IV records: an element of order 3 in $\mathrm{SL}_2(\mathbb{Z}_3)$ fixes no vector of T but a line of $T/3T$. The section also proves the facts about

extensions of two characters used in Lemma lem:old (a non-split extension has a unique stable line) and gives a second proof that Q_8 acts absolutely irreducibly on $\mathbb{F}_3^2$, a step of Proposition prop:ns.

Definition 4.16. A representation is *semisimple* if it is a sum of irreducible subrepresentations. The zero representation is semisimple.

Proposition 4.17. *Let V be a finite-dimensional representation of any group G over k.*

(i) The following are equivalent: (a) V is a sum of irreducible subrepresentations; (b) V is a direct sum of irreducible subrepresentations; (c) every subrepresentation of V has a G-stable complement.

(ii) Subrepresentations and quotients of a semisimple representation are semisimple.

(iii) (Isotypic decomposition.) For an irreducible S let V_S be the sum of the subrepresentations of V isomorphic to S. If V is semisimple, $V = \bigoplus_S V_S$ over the isomorphism classes of irreducible S, and $V_S \simeq S^{m_S}$, where $m_S \dim_k \operatorname{End}_G(S) = \dim_k \operatorname{Hom}_G(S, V)$. In particular $m_S = \dim \operatorname{Hom}_G(S, V)$ if S is absolutely irreducible.

Proof. (i) Suppose (a), $V = \sum_{i\in I} S_i$, and let U be a subrepresentation. Choose $J \subseteq I$ maximal such that the sum $U + \sum_{j\in J} S_j$ is direct. For every i, $S_i \cap (U \oplus \bigoplus_J S_j)$ is a subrepresentation of the irreducible S_i; if it were 0, $J \cup \{i\}$ would contradict maximality; so $S_i \subseteq U \oplus \bigoplus_J S_j$. Hence $V = U \oplus \bigoplus_J S_j$, which gives (c), and (b) for $U = 0$. (b) implies (a) trivially. Suppose (c), and let V' be the sum of all irreducible subrepresentations. If $V' \neq V$, a complement $C \neq 0$ exists; C contains a nonzero subrepresentation of minimal dimension, which is irreducible and lies in $V' \cap C = 0$, a contradiction. (ii) By the proof of (i), $V = U \oplus \bigoplus_J S_j$, so $V/U \simeq \bigoplus_J S_j$ is semisimple. Applying this to a complement C of U, with $V = C \oplus U$, shows that $U \simeq V/C$ is semisimple. (iii) Write $V = \bigoplus_i S_i$ by (b), and let W_S be the sum of the S_i isomorphic to S. If $T \subseteq V$ is irreducible and $T \simeq S$, its projection to any $S_i \not\simeq S$ is 0 by Theorem 4.10(i); so $T \subseteq W_S$. Hence $V_S = W_S$, $V = \bigoplus_S V_S$, and $V_S \simeq S^{m_S}$ with m_S the number of i with $S_i \simeq S$. Then $\operatorname{Hom}_G(S, V) = \bigoplus_i \operatorname{Hom}_G(S, S_i)$ has dimension $m_S \dim \operatorname{End}_G(S)$; the number m_S does not depend on the decomposition. □

Theorem 4.18 (Maschke)**.** *(i) Let G be finite and $\operatorname{char} k \nmid \#G$. Every finite-dimensional representation of G over k is semisimple.*

(ii) Let G be finite, R a commutative ring with $\#G \in R^\times$, and M an $R[G]$-module. Then $e_G = \frac{1}{\#G}\sum_{g\in G} g$ is a central idempotent of $R[G]$ with $e_G M = M^G$, $M = M^G \oplus (1 - e_G)M$ as $R[G]$-modules, and $(M/IM)^G = M^G/IM^G$ for every ideal I of R. In particular, for $R = \mathbb{Z}_\ell$ with $\ell \nmid \#G$ and a $\mathbb{Z}_\ell[G]$-lattice T, $(T/\ell^m T)^G = T^G/\ell^m T^G$: invariants commute with reduction.

Proof. (i) Let $U \subseteq V$ be a subrepresentation and $\pi\colon V \to U$ any k-linear projection ($\pi|_U = \mathrm{id}$; extend a basis of U to one of V). Such a π need not commute with G, and the idea is to average it over the group. Put $\pi' = \frac{1}{\#G}\sum_g g\pi g^{-1}$, which makes sense because $\#G \in k^\times$. Each term maps V into $gU = U$, so $\pi'(V) \subseteq U$. For $u \in U$, $g^{-1}u \in U$, so $g\pi g^{-1}u = gg^{-1}u = u$, and $\pi' u = \frac{1}{\#G} \cdot \#G \cdot u = u$. For $h \in G$,

$$h\pi' h^{-1} = \frac{1}{\#G}\sum_g (hg)\pi(hg)^{-1} = \pi',$$

since $g \mapsto hg$ permutes G. So π' is a G-equivariant projection onto U; then $V = U \oplus \ker \pi'$ (write $v = \pi' v + (v - \pi' v)$), and $\ker \pi'$ is G-stable because π' commutes with G. It is a stable complement; apply Proposition 4.17(i). (ii) $he_G = e_G = e_G h$ for $h \in G$, so e_G is central and $e_G^2 = \frac{1}{\#G} \sum_g g e_G = e_G$. If $m \in M^G$, $e_G m = m$; and $he_G m = e_G m$, so $e_G M = M^G$. Since e_G is a central idempotent, $M = e_G M \oplus (1 - e_G)M$ as $R[G]$-modules. Finally M/IM is an $R[G]$-module, so what was just proved, applied to it, gives $(M/IM)^G = e_G(M/IM)$; as e_G applied to the class of m is the class of $e_G m$, this is the image of $e_G M = M^G$, so $M^G \to (M/IM)^G$ is onto. The kernel of $M^G \to M/IM$ is $M^G \cap IM$, and if $x = \sum r_i m_i \in M^G$ with $r_i \in I$, then $x = e_G x = \sum r_i e_G m_i \in IM^G$. □

Two comments on the proof. First, the hypothesis $\operatorname{char} k \nmid \#G$ enters only through the factor $\frac{1}{\#G}$. Without it the sum $\sum_g g\pi g^{-1}$ is still G-equivariant with image in U, but on U it is multiplication by $\#G$, which is then 0. Second, the conclusion really fails then. In the permutation representation k^3 of S_3 (after Definition 4.2) with $\operatorname{char} k = 3$, the line $D = k(1,1,1)^t$ has no stable complement. Indeed, a stable complement C would give the G-equivariant projection $k^3 \to D$ along C; composed with $D \simeq k$, $c(1,1,1)^t \mapsto c$, it is a linear form $\lambda(x) = a_1x_1 + a_2x_2 + a_3x_3$ with $\lambda(gx) = \lambda(x)$ for all g (as G acts trivially on D) and $\lambda(1,1,1) = 1$. Invariance under the transposition exchanging x_i and x_j gives $a_i = a_j$, so $\lambda = a(x_1 + x_2 + x_3)$ and $\lambda(1,1,1) = 3a = 0$, a contradiction. Here 3 divides $\#S_3 = 6$.

In the paper 4.19. In Lemma lem:euler and Remark rem:types, for $\ell \geq 5$ the finite images of inertia (of order $2, 3, 4, 6$) have order prime to ℓ, so by (ii) their invariants on T and on $\operatorname{ad}^0 T$ commute with reduction modulo ℓ^m. At $\ell = 3$ this fails only for the elements of order 3 acting on T: $T^g = 0$ while $(T/3T)^g$ is a line (Proposition 4.72(ii)); that failure is the content of Lemma lem:IV. For an element of order 6, $T^g = 0 = (T/3T)^g$ (Proposition 4.72(iii)), and on $\operatorname{ad}^0 T$ it acts as $-g$, of order 3, whose invariant line $\mathbb{Z}_3(1 - 2g)$ reduces onto $(\operatorname{ad}^0 T/3)^g$ (Proposition 4.72(ii)): there the invariants still commute with reduction. In Proposition prop:ns the groups Q_8 and C_4 have order prime to 3, which is used in Proposition 4.26.

Example 4.20 (Failures of semisimplicity)**.** (a) $\mathrm{U} = \langle u \rangle \simeq C_3$ acting on $\mathbb{F}_3^2$. The line $\mathbb{F}_3 e_1$ is stable. A stable line is spanned by an eigenvector of u, and $\ker(u - 1) = \mathbb{F}_3 e_1$ is the only eigenspace; so $\mathbb{F}_3 e_1$ has no stable complement, $\mathbb{F}_3^2$ is indecomposable and not semisimple, and its composition factors (Theorem 4.21) are $\mathbf{1}, \mathbf{1}$. Maschke does not apply: $3 \mid \#\mathrm{U}$.

(b) The regular representation $\mathbb{F}_p[C_p] \simeq \mathbb{F}_p[x]/(x^p - 1) = \mathbb{F}_p[x]/((x-1)^p)$ (x a generator of C_p). Its subrepresentations are the ideals, which are the $((x-1)^j)$, $0 \leq j \leq p$, a chain: the representation is uniserial, with the single composition factor $\mathbf{1}$ of multiplicity p.

(c) For an infinite group Maschke fails even in characteristic 0: $\mathbb{Z}$ acting on $\mathbb{Q}_\ell^2$ by $m \mapsto \left(\begin{smallmatrix} 1 & mn' \\ 0 & 1 \end{smallmatrix}\right)$ with $n' \neq 0$ stabilises only the line $\mathbb{Q}_\ell e_1$ (as in (a)), so it is not semisimple. This is the shape of tame inertia at a multiplicative prime (Lemma lem:tamfactor).

(d) $\mathrm{B}(\mathbb{F}_3)$ on $\mathbb{F}_3^2$: it contains u, so $\mathbb{F}_3 e_1$ is its only stable line, and the representation is indecomposable and reducible. Its commutant is $\mathbb{F}_3$: a matrix commuting with $\sigma = \operatorname{diag}(1, -1)$ is diagonal, and $\operatorname{diag}(x, y)$ commutes with u iff $x = y$. So "$\operatorname{End}_G(V) = k$" does not imply irreducibility without semisimplicity.

Theorem 4.21 (Jordan-Hölder)**.** *Let A be a ring (here $k[G]$ or $\mathcal{O}[G]$) and M an A-module of finite length, for example a finite-dimensional representation or a finite $\mathcal{O}[G]$-module. Then M has a composition series $0 = M_0 \subset M_1 \subset \cdots \subset M_r = M$ with simple quotients M_i/M_{i-1}, and*

the length r and the multiset of isomorphism classes of the quotients (the composition factors*, with multiplicity) do not depend on the series.*

Proof. This is proved in Chapter 3 for modules of finite length over any ring; we do not prove it again. A finite-dimensional representation has finite length because a strictly increasing chain of subspaces has at most $\dim V + 1$ terms. □

Definition 4.22. The *semisimplification* of a finite-dimensional representation V is $V^{ss} = \bigoplus_{i=1}^{r} M_i/M_{i-1}$ for a composition series (M_i) of V.

Proposition 4.23. *(i) V^{ss} is well defined up to isomorphism; $V^{ss} \simeq V$ iff V is semisimple; and if $0 \to U \to V \to Q \to 0$ is exact, $V^{ss} \simeq U^{ss} \oplus Q^{ss}$.*

(ii) $\det(X - g \mid V) = \det(X - g \mid V^{ss})$ and $\operatorname{tr}(g \mid V) = \operatorname{tr}(g \mid V^{ss})$ for all $g \in G$.

(iii) If k is perfect and K/k algebraic, $(V^{ss})_K \simeq (V_K)^{ss}$.

Proof. (i) Well defined by Theorem 4.21. If $V = \bigoplus_i S_i$ with S_i irreducible, $0 \subset S_1 \subset S_1 \oplus S_2 \subset \cdots$ is a composition series with quotients S_i, so $V^{ss} \simeq V$; conversely V^{ss} is semisimple by definition. For the exact sequence, a composition series of U followed by the preimages of one of Q is a composition series of V. (ii) In a basis adapted to a composition series the matrix of g is block upper triangular with the matrices of g on the M_i/M_{i-1} on the diagonal. (iii) We do not prove this; see [37, Section 29] (over a perfect field an irreducible representation stays semisimple after an algebraic extension of scalars). It is not used below: Theorem 4.35 is proved over an arbitrary field without it. □

For example, for $\mathrm{U} = \langle u \rangle$ acting on $\mathbb{F}_3^2$ the series $0 \subset \mathbb{F}_3 e_1 \subset \mathbb{F}_3^2$ has quotients $\mathbf{1}$ and $\mathbf{1}$ (u acts on $\mathbb{F}_3^2/\mathbb{F}_3 e_1$ through its lower right entry 1), so $(\mathbb{F}_3^2)^{ss} \simeq \mathbf{1} \oplus \mathbf{1}$, while $\mathbb{F}_3^2$ itself is not semisimple. The semisimplification forgets the upper right entry of u, and (ii) says that it keeps everything the characteristic polynomials see. This is why $\bar{\rho}^{ss}$ is the part of a residual representation that congruences between Fourier coefficients can detect (Section 4.5).

Proposition 4.24 (Extensions of two characters)**.** *Let V be a two-dimensional representation of any group G over k with a stable line L, on which G acts by η_1, and let G act on V/L by η_2. In a basis $e_1 \in L$, e_2,*

$$\rho(g) = \begin{pmatrix} \eta_1(g) & b(g) \\ 0 & \eta_2(g) \end{pmatrix}, \qquad b(gh) = \eta_1(g)b(h) + b(g)\eta_2(h).$$

(i) The following are equivalent: V is semisimple; $V \simeq \eta_1 \oplus \eta_2$; V has a stable line other than L; there is $c \in k$ with $b(g) = c\,(\eta_2(g) - \eta_1(g))$ for all g (then $k(ce_1 + e_2)$ is stable).

(ii) If V is not semisimple (a non-split extension*), L is its only stable line. Hence if V' is another non-split extension, with sub-character η_1' and quotient character η_2', every isomorphism $V \simeq V'$ maps L onto L', and $\eta_1 = \eta_1'$, $\eta_2 = \eta_2'$.*

(iii) If $\eta_1 \neq \eta_2$ and V is semisimple, V has exactly two stable lines.

Proof. The cocycle identity is the upper right entry of $\rho(gh) = \rho(g)\rho(h)$. (i) If V is semisimple, L has a stable complement L', a second stable line, and $L' \simeq V/L$, so $V = L \oplus L' \simeq \eta_1 \oplus \eta_2$; if $V \simeq \eta_1 \oplus \eta_2$ it is semisimple. A line other than L is $k(ce_1 + e_2)$ for a unique c, and

$g(ce_1+e_2)=(c\eta_1(g)+b(g))e_1+\eta_2(g)e_2$ lies in $k(ce_1+e_2)$ iff $c\eta_1(g)+b(g)=c\eta_2(g)$. A second stable line is a complement of L. (ii) A second stable line would make V semisimple by (i). An isomorphism maps stable lines to stable lines, so L to L', and induces isomorphisms $L\simeq L'$ and $V/L\simeq V'/L'$ of one-dimensional representations, which are equalities of characters. (iii) In a basis v_1,v_2 of stable lines, $V=kv_1\oplus kv_2$ with characters $\eta_1\neq\eta_2$, a vector xv_1+yv_2 with $xy\neq 0$ spans a stable line only if $\eta_1(g)=\eta_2(g)$ for all g. □

For example, for U on $\mathbb{F}_3^2$ one has $\eta_1=\eta_2=\mathbf{1}$ and $b(u^m)=m$; the condition of (i) would require $b=c(\eta_2-\eta_1)=0$, so the extension is non-split, as found in Example 4.20(a). In general the condition of (i) says that b has the special form $c(\eta_2-\eta_1)$, determined by one constant. Dividing by η_2, the identity for b becomes

$$\frac{b(gh)}{\eta_2(gh)}=\frac{\eta_1(g)}{\eta_2(g)}\cdot\frac{b(h)}{\eta_2(h)}+\frac{b(g)}{\eta_2(g)},$$

which says that b/η_2 is a 1-cocycle of G with values in $k(\eta_1\eta_2^{-1})$, and the split case $b/\eta_2=-c\,(\eta_1\eta_2^{-1}-1)$ is a coboundary. This is the beginning of the cohomological reading of extensions, developed in Chapter 16.

In the paper 4.25. Lemma lem:old, case $p\,\|\,N$ with $\bar\rho$ ramified at p: "A non-split extension of two characters has a unique stable line, so the isomorphism $\bar\rho|_{D_p}\simeq\bar\rho_h|_{D_p}$ matches the sublines and hence the quotients" is (ii), applied over a common finite extension of $\mathbb{F}_\ell$. Lemma lem:tamfactor uses the shape $\left(\begin{smallmatrix}\chi_\ell\varepsilon & \varepsilon\kappa\\ 0 & \varepsilon\end{smallmatrix}\right)$ of the Tate representation: the corner $\varepsilon\kappa$ satisfies the cocycle identity above with $\eta_1=\chi_\ell\varepsilon$, $\eta_2=\varepsilon$ (convention B-C14; the cohomological reading is in Chapter 16).

Proposition 4.26 (Absolute irreducibility in dimension 2)**.** *Let $\rho\colon G\to\mathrm{GL}_2(k)$ be a representation.*

(i) If $\rho(G)$ is abelian, ρ is absolutely reducible.

(ii) If $\rho(G)$ is finite of order prime to $\operatorname{char}k$ and ρ is absolutely reducible, then $\rho_{\bar k}\simeq\eta_1\oplus\eta_2$ and $\rho(G)$ is abelian. Hence a finite non-abelian subgroup of $\mathrm{GL}_2(k)$ of order prime to $\operatorname{char}k$ acts absolutely irreducibly on k^2.

(iii) If $H\le G$ and $\operatorname{Res}_H\rho$ is absolutely irreducible, so is ρ.

(iv) On $\mathbb{F}_3^2$: Q_8 acts absolutely irreducibly, and hence so do $\mathrm{SL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ and $\mathrm{GL}_2(\mathbb{F}_3)$, which contain it; $N_s(\mathbb{F}_3)\simeq D_4$ acts absolutely irreducibly; C_4 and $C_{ns}(\mathbb{F}_3)$ do not. The Borel subgroup $\mathrm{B}(\mathbb{F}_3)$ is non-abelian and acts faithfully but reducibly: its order 12 is divisible by 3, and (ii) does not apply.

Proof. (i) Commuting operators on $\bar k^2$ have a common eigenvector: if all $\rho(g)$ are scalars any line is stable; otherwise take g_0 with $\rho(g_0)$ not scalar and an eigenvalue c of it; its eigenspace $\ker(\rho(g_0)-c)$ is a line (it is not everything), stable under every $\rho(g)$, which commutes with $\rho(g_0)$. (ii) $\rho_{\bar k}$ has a stable line L. The finite group $\rho(G)$ acts on $\bar k^2$ and has order prime to $\operatorname{char}\bar k=\operatorname{char}k$, so by Maschke (Theorem 4.18(i), applied to $\rho(G)$) L has a stable complement L', again a line. In a basis $v\in L$, $v'\in L'$ every $\rho(g)$ is diagonal, so $\rho_{\bar k}\simeq\eta_1\oplus\eta_2$ with η_1,η_2 the characters by which G acts on L and L', and $\rho(G)$ is abelian. The second sentence of (ii) is the contrapositive, for ρ the inclusion of the subgroup. (iii) A stable line of $\bar k^2$ for G is one for H. (iv) Q_8 is non-abelian of order 8, prime to 3, and acts faithfully; apply (ii) and then (iii) to the groups containing Q_8 (Chapter 1). $N_s(\mathbb{F}_3)$ is non-abelian of order 8. C_4 and $C_{ns}(\mathbb{F}_3)$ are cyclic; apply (i). $\mathrm{B}(\mathbb{F}_3)$ stabilises $\mathbb{F}_3e_1$. □

In the paper 4.27. Proposition prop:ns: "The first two act absolutely irreducibly on $\mathbb{F}_3^2$". The paper's argument is the commutator one of Chapter 1: a subgroup of $\mathrm{GL}_2(\overline{\mathbb{F}}_3)$ fixing a line lies in a Borel subgroup, whose commutator subgroup is unipotent, so abelian of exponent 3, while the commutator subgroups $\{\pm 1\}$ of Q_8 and Q_8 of $\mathrm{SL}_2(\mathbb{F}_3)$ are not. Proposition 4.26(ii), (iii) give a second proof: Q_8 is non-abelian of order prime to 3, and $\mathrm{SL}_2(\mathbb{F}_3)$ contains Q_8. A group that is merely non-abelian and acts faithfully need not act irreducibly, by the example of $\mathrm{B}(\mathbb{F}_3)$; this is why an argument of one of these two kinds is needed. "The third is abelian, hence absolutely reducible" is (i).

4.4 Characters in characteristic zero

This short section connects the chapter with the character theory of Riley-Hobson-Bence: over $\mathbb{C}$ a representation of a finite group is determined by its trace function, and the trace functions of the irreducible representations are orthonormal. The paper uses none of this directly; it is here for two reasons. It shows the reader where the familiar theory stops: in characteristic ℓ traces no longer determine semisimple representations (Example 4.32), which is why Brauer-Nesbitt in Lemma lem:old is applied with characteristic polynomials. And the two groups of order 8 of Proposition prop:ns, $N_s(\mathbb{F}_3) \simeq D_4$ and Q_8, are a classical pair with the same character table.

Definition 4.28. The *trace function* of a representation V is $\mathrm{tr}_V \colon G \to k$, $\mathrm{tr}_V(g) = \mathrm{tr}\,\rho(g)$. It is a class function ($\mathrm{tr}_V(xgx^{-1}) = \mathrm{tr}_V(g)$), $\mathrm{tr}_V(1) = \dim V$ (in k), and by Proposition 4.4 $\mathrm{tr}_{V\oplus W} = \mathrm{tr}_V + \mathrm{tr}_W$, $\mathrm{tr}_{V\otimes W} = \mathrm{tr}_V\,\mathrm{tr}_W$, $\mathrm{tr}_{V^\vee}(g) = \mathrm{tr}_V(g^{-1})$. For $k = \mathbb{C}$ and G finite, $\rho(g)$ has finite order, its eigenvalues are roots of unity, and $\mathrm{tr}_V(g^{-1}) = \overline{\mathrm{tr}_V(g)}$. In Riley-Hobson-Bence, and in most books on finite groups, tr_V is called the *character* of V; we avoid the word for trace functions because the paper's characters χ_{-3}, χ_ℓ, ψ are homomorphisms to $k^\times$ (one-dimensional representations, whose trace function is the character itself).

Theorem 4.29 (Orthogonality)**.** *Let G be finite, $k = \mathbb{C}$, and $\langle \phi, \psi\rangle = \frac{1}{\#G}\sum_{g\in G}\phi(g)\overline{\psi(g)}$ on class functions.*

(i) For irreducible V, W: $\langle \mathrm{tr}_V, \mathrm{tr}_W\rangle = 1$ if $V \simeq W$ and 0 otherwise.

(ii) For all V, W: $\dim \mathrm{Hom}_G(V,W) = \langle \mathrm{tr}_W, \mathrm{tr}_V\rangle$. A representation V is irreducible iff $\langle \mathrm{tr}_V, \mathrm{tr}_V\rangle = 1$, and two representations with the same trace function are isomorphic.

(iii) The trace functions $\mathrm{tr}_{V_1}, \dots, \mathrm{tr}_{V_r}$ of the irreducible representations (up to isomorphism) form an orthonormal basis of the space of class functions; so r is the number of conjugacy classes; and $\sum_i (\dim V_i)^2 = \#G$.

(iv) Each $\dim V_i$ divides $\#G$.

Proof. (ii) By Proposition 4.5, $\mathrm{Hom}_G(V,W) \simeq (V^\vee \otimes W)^G$, which is the image of the idempotent e_G of Theorem 4.18(ii) acting on $V^\vee \otimes W$. An idempotent p satisfies $p(p-1) = 0$, so the space is $\mathrm{im}\,p \oplus \ker p$ with p acting by 1 and by 0, and $\mathrm{tr}\,p = \dim \mathrm{im}\,p$ (an integer, read in $\mathbb{C}$). By linearity of the trace, Proposition 4.4(i) and Definition 4.28 ($\mathrm{tr}_{V^\vee}(g) = \mathrm{tr}_V(g^{-1}) = \overline{\mathrm{tr}_V(g)}$),

$$\dim \mathrm{Hom}_G(V,W) = \mathrm{tr}(e_G \mid V^\vee \otimes W) = \frac{1}{\#G}\sum_g \mathrm{tr}_{V^\vee}(g)\,\mathrm{tr}_W(g)$$
$$= \frac{1}{\#G}\sum_g \mathrm{tr}_W(g)\overline{\mathrm{tr}_V(g)} = \langle \mathrm{tr}_W, \mathrm{tr}_V\rangle.$$

(i) follows from (ii) and Theorem 4.10(ii); the value is real, so the order of the arguments does not matter. By Maschke, $V \simeq \bigoplus_i V_i^{m_i}$, and by (i) $\langle \mathrm{tr}_V, \mathrm{tr}_V\rangle = \sum_i m_i^2$, which is 1 iff V is irreducible; and $m_i = \langle \mathrm{tr}_V, \mathrm{tr}_{V_i}\rangle$ is determined by tr_V. (iii) Orthonormality is (i). The regular representation $\mathbb{C}[G]$ has $\mathrm{tr}(1) = \#G$ and $\mathrm{tr}(g) = 0$ for $g \neq 1$ (a nontrivial g moves every basis vector), so $\langle \mathrm{tr}_{\mathbb{C}[G]}, \mathrm{tr}_{V_i}\rangle = \dim V_i$, $\mathbb{C}[G] \simeq \bigoplus_i V_i^{\dim V_i}$, and $\#G = \sum_i (\dim V_i)^2$. Let ϕ be a class function orthogonal to every tr_{V_i}. For each irreducible V, the operator $\Phi_V = \sum_g \overline{\phi(g)}\rho_V(g)$ commutes with G (ϕ is a class function), so it is a scalar c by Schur, and $c \dim V = \mathrm{tr}\,\Phi_V = \#G\,\langle \mathrm{tr}_V, \phi\rangle = 0$. So Φ vanishes on every irreducible, hence on $\mathbb{C}[G]$, and applied to $1 \in \mathbb{C}[G]$ it gives $\sum_g \overline{\phi(g)} g = 0$, so $\phi = 0$. Hence the tr_{V_i} span the class functions, whose dimension is the number of conjugacy classes. (iv) We do not prove this; see [173, Section 6.5]. □

Corollary 4.30. *If* $\mathrm{char}\, k = 0$*, two semisimple finite-dimensional representations of any group* G *with the same trace function are isomorphic.*

Proof. This is the last statement of Theorem 4.35 (traces suffice in characteristic 0), together with Proposition 4.23(i); the proof of that theorem does not use this corollary. □

Example 4.31 (The character tables of D_4 and Q_8)**.** Take $D_4 = N_s(\mathbb{F}_3) = \langle J, \sigma\rangle$ (rotation J, reflection σ; Chapter 1) and $Q_8 = \{\pm 1, \pm J, \pm j, \pm k\}$ with $j = \left(\begin{smallmatrix} 1 & -1 \\ -1 & -1 \end{smallmatrix}\right)$, $k = Jj$. Both have five conjugacy classes, and their irreducible trace functions over $\mathbb{C}$ are:

D_4	1	-1	$\pm J$	$\pm\sigma$	$\pm w$
Q_8	1	-1	$\pm J$	$\pm j$	$\pm k$
λ_0	1	1	1	1	1
λ_1	1	1	1	-1	-1
λ_2	1	1	-1	1	-1
λ_3	1	1	-1	-1	1
tr_2	2	-2	0	0	0

The four characters factor through the quotient by $\{\pm 1\}$, which is V_4 for both groups; for D_4, $\lambda_1 = \det$ (kernel C_4), λ_2 has kernel $C_s(\mathbb{F}_3) = \{\pm 1, \pm\sigma\}$ and λ_3 kernel $\{\pm 1, \pm w\}$. The orthogonality relations and $4 \cdot 1^2 + 2^2 = 8$ show the table is complete. In detail: the classes have $1, 1, 2, 2, 2$ elements, so for instance $\langle \mathrm{tr}_2, \mathrm{tr}_2\rangle = \frac{1}{8}(2^2 + (-2)^2) = 1$ and $\langle \lambda_1, \lambda_2\rangle = \frac{1}{8}(1 + 1 - 2 - 2 + 2) = 0$. For D_4 the row tr_2 is read off the matrices ($\mathrm{tr}\, J = \mathrm{tr}\,\sigma = \mathrm{tr}\, w = 0$, $\mathrm{tr}(-1) = -2$). For Q_8 it is forced: by the proof of Theorem 4.29(iii), $\sum_i \dim V_i\ \mathrm{tr}_{V_i}(g) = \mathrm{tr}(g \mid \mathbb{C}[G]) = 0$ for $g \neq 1$, so the remaining irreducible representation, of degree $\sqrt{8-4} = 2$, has $\mathrm{tr}_2(g) = -\frac{1}{2}\sum_{j=0}^{3} \lambda_j(g)$, which is -2 at -1 and 0 on the other three classes $\neq \{1\}$. Yet $D_4 \not\simeq Q_8$ (D_4 has five involutions, Q_8 one). The two-dimensional representation of D_4 is given by the integral matrices J, σ, so it is defined over $\mathbb{Q}$, and its reduction modulo 3 is the standard representation of $N_s(\mathbb{F}_3)$. That of Q_8 is not defined over $\mathbb{R}$: its Frobenius-Schur indicator $\frac{1}{8}\sum_g \mathrm{tr}_2(g^2)$ is $\frac{1}{8}(2 \cdot 2 + 6 \cdot (-2)) = -1$, which for an irreducible representation means that it is not realisable over $\mathbb{R}$ (we do not prove this; see [173, Section 13.2]). Over $\mathbb{F}_3$, however, it is realised by the standard representation of $Q_8 \subset \mathrm{SL}_2(\mathbb{F}_3)$, whose trace function is the reduction of tr_2.

Example 4.32 (Traces do not suffice in characteristic p)**.** Let $G = C_2 = \{1, s\}$ and $k = \mathbb{F}_3$. The semisimple representations $\mathbf{1}^{\oplus 3}$ and $\mathrm{sgn}^{\oplus 3}$ ($s \mapsto -1$) have trace functions $(3, 3)$ and $(3, -3)$, both $(0, 0)$ in $\mathbb{F}_3$, but they are not isomorphic: $\det(X - s)$ is $(X-1)^3$, respectively $(X+1)^3$. In general, if $n < p$ (or $p = 0$), the traces of $g, g^2, \ldots, g^n$ determine the characteristic polynomial of

g on an n-dimensional space by Newton's identities, $je_j = \sum_{i=1}^{j}(-1)^{i-1}e_{j-i}p_i$ for the elementary symmetric functions e_j and power sums $p_i = \operatorname{tr}(g^i)$ of the eigenvalues, which can be solved for the e_j because $1,\dots,n$ are invertible. For $n=2$ Newton's identities read $e_1 = p_1$ and $2e_2 = e_1p_1 - p_2$, so $\det g = \frac{1}{2}(\operatorname{tr}(g)^2 - \operatorname{tr}(g^2))$ if $2 \in k^\times$; in characteristic 2, $\operatorname{tr}(g^2) = \lambda_1^2 + \lambda_2^2 = \operatorname{tr}(g)^2$ carries no information about $\det g$. In any case the characteristic polynomial $X^2 - \operatorname{tr}(g)X + \det(g)$ is determined by the trace and the determinant in every characteristic.

Warning 4.33. In characteristic ℓ the right invariant of a representation is the family of characteristic polynomials, not the trace function. The paper's representations have dimension 2 and determinant $\bar{\chi}_\ell$, so for them traces do suffice (Corollary 4.36(i)): "$a_p(h) \equiv a_p(f) \pmod{\lambda}$ for all primes $p \nmid \ell N$" is a statement about traces of Frobenius elements, and it determines the semisimplification.

4.5 The theorem of Brauer and Nesbitt

This section proves that a semisimple representation over any field is determined by the characteristic polynomials of the elements of the group (Brauer and Nesbitt). With the Chebotarev density theorem (Chapter 5) it is the reason why a congruence $a_p(h) \equiv a_p(f) \pmod{\lambda}$ for almost all p gives $\bar{\rho}_h \simeq \bar{\rho}$, which is the first step of the paper's Lemma lem:old. The proof needs the density theorem of Jacobson and Burnside, proved first.

Theorem 4.34 (Density theorem of Jacobson and Burnside)**.** *Let G be any group, $S_1,\dots,S_r$ pairwise non-isomorphic irreducible finite-dimensional representations over k, and $D_i = \operatorname{End}_G(S_i)$.*

(a) The image of $k[G] \to \prod_i \operatorname{End}_k(S_i)$ is $\prod_i \operatorname{End}_{D_i}(S_i)$.

(b) If k is algebraically closed, the image is $\prod_i \operatorname{End}_k(S_i)$. In particular, for each i there is $x \in k[G]$ acting on S_i as a projector of rank one and on every S_j, $j \neq i$, as 0.

Proof. (a) Let A be the image. Each element of $k[G]$ commutes with D_i on S_i, so $A \subseteq \prod_i \operatorname{End}_{D_i}(S_i)$. By Theorem 4.10(i), D_i is a division algebra and S_i is a finite-dimensional (left) D_i-vector space; let $x_{i1},\dots,x_{in_i}$ be a D_i-basis. Put $M = \bigoplus_i S_i^{n_i}$, a semisimple representation, and $x = (x_{ij})_{i,j} \in M$. The subrepresentation $k[G]x = Ax$ of the semisimple M has a G-stable complement C (Proposition 4.17(i)), and the projection π of $M = Ax \oplus C$ onto Ax along C is a G-map: $\pi \in \operatorname{End}_G(M)$. We describe $\operatorname{End}_G(M)$. A G-map $M \to M$ has components $S_i \to S_j$ between the summands, and those with $i \neq j$ vanish by Schur, since $S_i \not\simeq S_j$. So a G-endomorphism of M is a family, over i, of G-endomorphisms of $S_i^{n_i}$, and each of these is an $n_i \times n_i$ matrix (d_{ab}) with entries $d_{ab} \in D_i$, acting by $(s_b)_b \mapsto (\sum_b d_{ab}s_b)_a$. Thus $\operatorname{End}_G(M) = \prod_i \mathrm{M}_{n_i}(D_i)$. Now let $\phi = (\phi_i) \in \prod_i \operatorname{End}_{D_i}(S_i)$ and let Φ act on M by ϕ_i on each copy of S_i. As ϕ_i commutes with every $d \in D_i$, the map Φ, which acts by ϕ_i on each coordinate of $S_i^{n_i}$, commutes with every such matrix: $\Phi((\sum_b d_{ab}s_b)_a) = (\sum_b d_{ab}\phi_i(s_b))_a$. In particular Φ commutes with π. Hence $\Phi(x) = \Phi(\pi x) = \pi\Phi(x) \in Ax$: there is $\alpha \in A$ with $\alpha x_{ij} = \phi_i(x_{ij})$ for all i,j. On S_i, both α and ϕ_i are D_i-linear and agree on a D_i-basis, so they are equal. Thus $\phi = \alpha \in A$. (b) If $k = \bar{k}$ then $D_i = k$ by Theorem 4.10(ii), so $\operatorname{End}_{D_i}(S_i) = \operatorname{End}_k(S_i)$; take the element of A that is a rank-one projector on S_i and 0 on the other factors. □

For example, let C_4 act on $S = \mathbb{F}_3^2$ (Example 4.14). Then $D = \operatorname{End}_{C_4}(S) = \mathbb{F}_3[J] \simeq \mathbb{F}_9$, and S is a one-dimensional D-vector space, so $\operatorname{End}_D(S) = D$: (a) says that the image of $\mathbb{F}_3[C_4]$ in the 4-dimensional $\operatorname{End}_{\mathbb{F}_3}(S)$ is the 2-dimensional $\mathbb{F}_3[J]$, which is visible directly (the image is

spanned by the powers of J). Over $\mathbb{F}_9$, $S_{\mathbb{F}_9} \simeq \psi \oplus \psi^{-1}$ is a sum of two non-isomorphic characters, and (b) provides an element of $\mathbb{F}_9[C_4]$ acting by 1 on ψ and by 0 on ψ^{-1}; one is $x = \frac{1}{2}(1 - iJ)$, since J acts by i on ψ and by $-i$ on ψ^{-1}, and $1 - i \cdot i = 2$, $1 - i \cdot (-i) = 0$.

Theorem 4.35 (Brauer-Nesbitt)**.** *Let G be any group, k any field, and V_1, V_2 finite-dimensional representations of G over k with*

$$\det(X - \rho_1(g)) = \det(X - \rho_2(g)) \quad \text{in } k[X] \text{ for every } g \in G.$$

Then V_1 and V_2 have the same composition factors with multiplicities, that is, $V_1^{ss} \simeq V_2^{ss}$. If $\operatorname{char} k = 0$, or if $\dim V_1 < \operatorname{char} k$ and $\dim V_2 < \operatorname{char} k$, the equality $\operatorname{tr} \rho_1(g) = \operatorname{tr} \rho_2(g)$ for all g suffices.

Proof. We prove both statements together; "the hypothesis" means equal characteristic polynomials, or, in the two special cases, equal traces.

Step 0. By Proposition 4.23(ii) we may replace V_1, V_2 by V_1^{ss}, V_2^{ss}.

Step 1: reduction to $k = \bar{k}$. Let S, S' be non-isomorphic irreducible representations over k. By Theorem 4.34(a) with $r = 2$ there is $x \in k[G]$ acting as 1 on S and as 0 on S'. Then x acts as the identity on $S_{\bar{k}}$, hence on all its subquotients, and as 0 on $S'_{\bar{k}}$; so x acts as 1 on every composition factor of $S_{\bar{k}}$ and as 0 on every composition factor of $S'_{\bar{k}}$, so $S_{\bar{k}}$ and $S'_{\bar{k}}$ have no common composition factor. If V has composition factors S with multiplicities $m_S(V)$, a composition series of V gives a filtration of $V_{\bar{k}}$ with quotients $S_{\bar{k}}$, so the multiset of composition factors of $V_{\bar{k}}$ is $\sum_S m_S(V)\, c(S_{\bar{k}})$, where the multisets $c(S_{\bar{k}})$ of composition factors of the $S_{\bar{k}}$ are nonempty with pairwise disjoint supports. Hence the composition factors of $V_{1,\bar{k}}$ and $V_{2,\bar{k}}$ agree iff $m_S(V_1) = m_S(V_2)$ for all S. As the hypothesis is unchanged by extending scalars, we may assume $k = \bar{k}$, and (Step 0) that V_1, V_2 are semisimple.

Step 2: cancellation. Write $V_1 \simeq C \oplus B_1$ and $V_2 \simeq C \oplus B_2$ where $C = \bigoplus_S S^{\min(m_S(V_1), m_S(V_2))}$; then B_1 and B_2 are semisimple without a common irreducible constituent. We show $B_1 = B_2 = 0$. The hypothesis passes to B_1, B_2: traces by subtraction, and characteristic polynomials because $\det(X - g \mid V_i) = \det(X - g \mid C) \det(X - g \mid B_i)$ and $k[X]$ is a domain. We argue by induction on $\dim B_1 + \dim B_2$; if it is 0 there is nothing to prove.

Step 3: multiplicities modulo p. The traces of B_1 and B_2 agree on G (they are coefficients of the characteristic polynomials), hence on all of $k[G]$ by linearity. Let S be an irreducible constituent of B_1, of multiplicity $m \geq 1$. By Theorem 4.34(b) applied to the distinct irreducible constituents of $B_1 \oplus B_2$, there is $x \in k[G]$ acting on S as a projector of rank one and as 0 on all the other constituents. Write $B_1 \simeq S^m \oplus B_1''$ with S not a constituent of B_1''; then x acts as a rank-one projector on each of the m copies of S and as 0 on B_1'', so $\operatorname{tr}(x \mid B_1) = m \cdot 1$. All constituents of B_2 differ from S, so x acts on B_2 as 0. Hence $m \cdot 1 = \operatorname{tr}(x \mid B_1) = \operatorname{tr}(x \mid B_2) = 0$ in k. If $\operatorname{char} k = 0$ this is impossible, so $B_1 = 0$, and symmetrically $B_2 = 0$. If $p = \operatorname{char} k > 0$, then $p \mid m$; if moreover $\dim V_1 < p$, then $m \leq \dim B_1 \leq \dim V_1 < p$ is impossible, so $B_1 = 0$; exchanging the roles of B_1 and B_2, $\dim V_2 < p$ gives $B_2 = 0$. This proves the statements about traces.

Step 4: dividing by p. In the remaining case ($p > 0$, characteristic polynomials), Step 3, applied to each constituent of B_1 and, with the roles exchanged, to each constituent of B_2, shows that every multiplicity in B_1 and in B_2 is divisible by p, so $B_i \simeq B_i'^{\oplus p}$ with B_i' semisimple, and $\det(X - g \mid B_i) = \det(X - g \mid B_i')^p$. The map $f \mapsto f^p$ is an injective ring endomorphism of $k[X]$ (it is additive in characteristic p, and $k[X]$ is a domain), so $\det(X - g \mid B_1') = \det(X - g \mid B_2')$ for all g. The representations B_1', B_2' have no common constituent and $\dim B_1' + \dim B_2' < \dim B_1 + \dim B_2$ unless both are 0; by induction $B_1' = B_2' = 0$, so $B_1 = B_2 = 0$. $\square$

Corollary 4.36. *(i) If* $\dim V_1 = \dim V_2 = 2$, $\det\rho_1 = \det\rho_2$ *and* $\operatorname{tr}\rho_1 = \operatorname{tr}\rho_2$ *on* G, *then* $V_1^{ss} \simeq V_2^{ss}$ *(in every characteristic).*

(ii) Let $k \subseteq k'$ *be fields,* V_1 *a representation over* k *and* V_2 *one over* k', *with* $\det(X-\rho_1(g)) = \det(X-\rho_2(g))$ *for all* g. *If* $V_1 \otimes_k k'$ *is irreducible (for instance if* V_1 *is absolutely irreducible), then* $V_2 \simeq V_1 \otimes_k k'$; *no semisimplicity of* V_2 *is assumed.*

(iii) The irreducibility of $V_1 \otimes_k k'$ *cannot be weakened to that of* V_1. *First, the irreducibility of* V_1 *does not make* V_2 *irreducible: for* C_4 *acting on* $V_1 = \mathbb{F}_3^2$ *and* $V_2 = \psi \oplus \psi^{-1}$ *over* $\mathbb{F}_9$ *(Example 4.14),* V_1 *is irreducible and* V_2 *is not. This example does not contradict the conclusion of (ii), since here* $V_2 \simeq V_1 \otimes \mathbb{F}_9$. *A genuine counterexample to the conclusion is the following. For the group* $G = \left\{ \left(\begin{smallmatrix} x & y \\ 0 & x^3 \end{smallmatrix}\right) : x \in \mathbb{F}_9^\times, y \in \mathbb{F}_9 \right\}$, *its standard representation* V_2 *on* $\mathbb{F}_9^2$ *and the representation* V_1 *on* $\mathbb{F}_9 = \mathbb{F}_3^2$ *by multiplication by* x *have the same characteristic polynomials* $(X-x)(X-x^3)$ *and* V_1 *is irreducible over* $\mathbb{F}_3$, *but* V_2 *is not semisimple while* $V_1 \otimes \mathbb{F}_9$ *is, so* $V_2 \not\simeq V_1 \otimes \mathbb{F}_9$.

Proof. (i) The characteristic polynomial of a 2×2 matrix is $X^2 - \operatorname{tr}(g)X + \det(g)$; apply Theorem 4.35. (ii) Apply Theorem 4.35 over k' to $V_1 \otimes_k k'$ and V_2: $V_2^{ss} \simeq V_1 \otimes_k k'$ is irreducible, so V_2 has a single composition factor, is irreducible, and equals V_2^{ss}. (iii) In the second example, an element $x \in \mathbb{F}_9^\times$ of order 8 acts on $\mathbb{F}_9$ by multiplication with eigenvalues x, x^3 over $\mathbb{F}_9$; the $\mathbb{F}_3$-subspaces of $\mathbb{F}_9$ stable under multiplication by $\mathbb{F}_9^\times$ are 0 and $\mathbb{F}_9$, so V_1 is irreducible, and $V_1 \otimes \mathbb{F}_9$ is the sum of the two characters $g \mapsto x$, $g \mapsto x^3$. In V_2 the line $\mathbb{F}_9 e_1$ is stable and is the only stable line, because G contains $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$; so V_2 is not semisimple (Proposition 4.24). □

In the paper 4.37. Lemma lem:old: "$\bar\rho_h \simeq \bar\rho$ over a common finite extension of $\mathbb{F}_\ell$, by Chebotarev and Brauer-Nesbitt, $\bar\rho$ being irreducible, hence absolutely irreducible". The residual representation $\bar\rho_h$ of the newform h lives over the residue field k' of the coefficient ring of h, and $\bar\rho$ over $\mathbb{F}_\ell$. For $p \nmid \ell N$ both have characteristic polynomial $X^2 - a_p X + p$ at Frob_p, with $a_p(h) \equiv a_p(f)$; by Chebotarev these elements are dense, so the characteristic polynomials agree on all of $G_{\mathbb{Q}}$ (Chapter 5). Then Corollary 4.36(ii), with $\bar\rho$ absolutely irreducible (Proposition 4.13), gives $\bar\rho_h \simeq \bar\rho \otimes k'$; with only $\bar\rho$ irreducible over $\mathbb{F}_\ell$ one would get $\bar\rho_h^{ss} \simeq (\bar\rho \otimes k')^{ss}$ and nothing more, by (iii).

4.6 Restriction, induction, Frobenius reciprocity, Mackey and Clifford

This section develops induced representations and their behaviour under restriction to a subgroup of index 2. In the paper, the image $N_s(\mathbb{F}_3)$ of Proposition prop:ns gives a representation induced, over $\mathbb{F}_9$, from a character of order 4 of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$, and for $\bar\rho$ irreducible the condition of Theorem thm:main, absolute irreducibility on $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell^*}))$, is, by Clifford theory (Theorem 4.44), the condition that $\bar\rho$ is not induced from $\mathbb{Q}(\sqrt{\ell^*})$, equivalently $\bar\rho \not\simeq \bar\rho \otimes \chi_{\ell^*}$ (Lemma lem:h0 for $\ell = 3$, Proposition prop:Sf).

Definition 4.38. Let $H \le G$ and let W be a representation of H over k (or an $R[H]$-module). The *induced representation* is $\mathrm{Ind}_H^G W = k[G] \otimes_{k[H]} W$, with G acting on the left factor. For a representation V of G, $\mathrm{Res}_H^G V$ (or $\mathrm{Res}_H V$) is V viewed as a representation of H. For $s \in G$ and a representation W of a subgroup H, W^s is the representation of sHs^{-1} on the space W

given by $x \mapsto \rho_W(s^{-1}xs)$. If H is normal, W^s is again a representation of H; for a character ψ of H, $\psi^s(x) = \psi(s^{-1}xs)$.

Concretely (Proposition 4.39 below), for $[G:H] = m$ the space $\operatorname{Ind}_H^G W$ is a direct sum of m copies $s_i \otimes W$ of W, one for each coset s_iH; G permutes the copies as it permutes the cosets, and acts between them through elements of H. The tensor product over $k[H]$ is what makes this independent of the choice of representatives: $sx \otimes w = s \otimes xw$ for $x \in H$. For example, $\operatorname{Ind}_H^G \mathbf{1}$ is the permutation representation on G/H. The convention for W^s matters for inverses below: with $W^s(x) = \rho_W(s^{-1}xs)$, the subspace $s \otimes W$ of $\operatorname{Ind}_H^G W$ is a copy of W^s (Proposition 4.39(i)); some books use $\rho_W(sxs^{-1})$, which is our $W^{s^{-1}}$. For a normal subgroup H of index 2 the two agree up to isomorphism: W^s is the conjugate of $W^{s^{-1}}$ by $s^2 \in H$, and for any representation U of H and $y \in H$ the operator $\rho_U(y)$ is an isomorphism $U^y \simeq U$.

Proposition 4.39. *Let $H \le G$ have finite index m and choose $G = \bigsqcup_{i=1}^m s_iH$ with $s_1 = 1$.*

(i) $\operatorname{Ind}_H^G W = \bigoplus_i s_i \otimes W$, $\dim \operatorname{Ind}_H^G W = m \dim W$, *and if $gs_i = s_jx$ with $x \in H$, then $g(s_i \otimes w) = s_j \otimes xw$. The subspace $s_i \otimes W$ is $s_iHs_i^{-1}$-stable and isomorphic to W^{s_i}.*

(ii) $\operatorname{tr}(g \mid \operatorname{Ind}_H^G W) = \sum_{i:\, s_i^{-1}gs_i \in H} \operatorname{tr}(s_i^{-1}gs_i \mid W)$.

(iii) Let $[G:H] = 2$, $s \notin H$. Then $\operatorname{tr}(x \mid \operatorname{Ind} W) = \operatorname{tr}(x \mid W) + \operatorname{tr}(s^{-1}xs \mid W)$ for $x \in H$ and $\operatorname{tr}(g \mid \operatorname{Ind} W) = 0$ for $g \notin H$. For a character ψ of H, in the basis $1 \otimes 1$, $s \otimes 1$ of $\operatorname{Ind}_H^G \psi$,

$$x \mapsto \begin{pmatrix} \psi(x) & 0 \\ 0 & \psi^s(x) \end{pmatrix} \ (x \in H), \qquad s \mapsto \begin{pmatrix} 0 & \psi(s^2) \\ 1 & 0 \end{pmatrix}.$$

Proof. (i) $k[G]$ is a free right $k[H]$-module with basis $s_1, \dots, s_m$, so $k[G] \otimes_{k[H]} W = \bigoplus_i s_i \otimes W$, and $g(s_i \otimes w) = s_jx \otimes w = s_j \otimes xw$. For $y = s_ixs_i^{-1}$, $y(s_i \otimes w) = s_ix \otimes w = s_i \otimes xw$, so $w \mapsto s_i \otimes w$ is an isomorphism $W^{s_i} \to s_i \otimes W$. (ii) By (i), g maps the block $s_i \otimes W$ into $s_j \otimes W$; the diagonal blocks are those with $j = i$, that is, $s_i^{-1}gs_i = x \in H$, where g acts as x on W. (iii) With $s_1 = 1$, $s_2 = s$: for $x \in H$ both blocks are diagonal ($s^{-1}xs \in H$ as H is normal), and for $g \notin H$ neither is. For ψ: $x(1 \otimes 1) = 1 \otimes \psi(x)$, $x(s \otimes 1) = s(s^{-1}xs) \otimes 1 = \psi^s(x)\, s \otimes 1$, $s(1 \otimes 1) = s \otimes 1$ and $s(s \otimes 1) = s^2 \otimes 1 = \psi(s^2)\, 1 \otimes 1$. □

Theorem 4.40 (Frobenius reciprocity)**.** *Let $H \le G$, W a representation of H and V one of G, over a field or a commutative ring.*

(i) The map $\phi \mapsto \phi(1 \otimes -)$ is an isomorphism $\operatorname{Hom}_G(\operatorname{Ind}_H^G W, V) \simeq \operatorname{Hom}_H(W, \operatorname{Res}_H V)$.

(ii) If $[G:H]$ is finite, with $\pi\colon \operatorname{Ind}_H^G W \to W$ the projection onto $1 \otimes W$ along $\bigoplus_{i \ge 2} s_i \otimes W$, the map $\phi \mapsto \pi \circ \phi$ is an isomorphism $\operatorname{Hom}_G(V, \operatorname{Ind}_H^G W) \simeq \operatorname{Hom}_H(\operatorname{Res}_H V, W)$.

In characteristic 0 with G finite, (i) and Theorem 4.29(ii) give $\langle \operatorname{tr}_{\operatorname{Ind} W}, \operatorname{tr}_V \rangle_G = \langle \operatorname{tr}_W, \operatorname{tr}_{\operatorname{Res} V} \rangle_H$.

Proof. (i) $w \mapsto \phi(1 \otimes w)$ is H-linear because $\phi(1 \otimes xw) = \phi(x \otimes w) = x\phi(1 \otimes w)$. The inverse sends $\psi \in \operatorname{Hom}_H(W, V)$ to $y \otimes w \mapsto y\psi(w)$, which is well defined on $k[G] \otimes_{k[H]} W$ ($yx \otimes w$ and $y \otimes xw$ have the same image, ψ being H-linear) and G-linear. The two constructions are inverse to each other: starting from ψ one recovers $w \mapsto 1 \cdot \psi(w) = \psi(w)$, and starting from ϕ one obtains $y \otimes w \mapsto y\phi(1 \otimes w) = \phi(y \otimes w)$. (ii) π is H-linear: H preserves $1 \otimes W$, and permutes the blocks $s_i \otimes W$, $i \ge 2$ (if $xs_i \in s_1H = H$ then $s_i \in H$). Given $\psi \in \operatorname{Hom}_H(V, W)$ put $\Psi(v) = \sum_i s_i \otimes \psi(s_i^{-1}v)$.

This does not depend on the representatives, since $s_i x \otimes \psi(x^{-1}s_i^{-1}v) = s_i \otimes \psi(s_i^{-1}v)$. It is G-linear: $g\Psi(v) = \sum_i gs_i \otimes \psi(s_i^{-1}v)$, and $t_i = gs_i$ is another system of representatives with $t_i^{-1}gv = s_i^{-1}v$, so $g\Psi(v) = \sum_i t_i \otimes \psi(t_i^{-1}gv) = \Psi(gv)$. Then $\pi\Psi = \psi$ (the term $i = 1$). Conversely, for a G-map ϕ write $\phi(v) = \sum_i s_i \otimes w_i$; then $\pi(\phi(s_i^{-1}v)) = \pi(s_i^{-1}\phi(v)) = w_i$, because $s_i^{-1}(s_j \otimes w_j) = s_i^{-1}s_j \otimes w_j$ lies in the block $1 \otimes W$ for $j = i$ and in another block for $j \neq i$ ($s_i^{-1}s_j \in H$ only for $j = i$); so the map Ψ built from $\psi = \pi\phi$ is ϕ. □

Proposition 4.41 (Projection formula)**.** *Let $H \leq G$ have finite index.*

(i) For a representation W of H and U of G, $y \otimes (w \otimes u) \mapsto (y \otimes w) \otimes yu$ is a G-isomorphism $\operatorname{Ind}_H^G(W \otimes \operatorname{Res}_H U) \simeq \operatorname{Ind}_H^G W \otimes U$. In particular, if χ is a character of G trivial on H, then $\operatorname{Ind}_H^G W \otimes \chi \simeq \operatorname{Ind}_H^G W$.

(ii) $\operatorname{Ind}_H^G \mathbf{1} = k[G/H]$, the permutation representation on the cosets. If $[G : H] = 2$ and $\operatorname{char} k \neq 2$, then $\operatorname{Ind}_H^G \mathbf{1} \simeq \mathbf{1} \oplus \chi_H$, where $\chi_H \colon G \to \{\pm 1\}$ is the character with kernel H.

(iii) $\operatorname{Ind}_K^G \operatorname{Ind}_H^K \simeq \operatorname{Ind}_H^G$ for $H \leq K \leq G$; $\operatorname{Ind}(W \oplus W') \simeq \operatorname{Ind} W \oplus \operatorname{Ind} W'$; and $(\operatorname{Ind}_H^G W)_K \simeq \operatorname{Ind}_H^G(W_K)$ for a field extension K/k.

Proof. (i) The formula is compatible with $yx \otimes (w \otimes u) = y \otimes (xw \otimes xu)$ ($x \in H$), since both go to $(yx \otimes w) \otimes yxu$; it is G-linear. On the block $s_i \otimes (W \otimes U)$ it is $w \otimes u \mapsto (s_i \otimes w) \otimes s_i u$, a bijection onto $(s_i \otimes W) \otimes U$; so it is bijective. If $\chi|_H = 1$, then $\operatorname{Res}_H \chi = \mathbf{1}$ and $W \otimes \mathbf{1} = W$. (ii) $k[G] \otimes_{k[H]} k$ has basis $s_i \otimes 1$, permuted by G as the cosets $s_i H$. For index 2 the vectors $1 \otimes 1 \pm s \otimes 1$ are fixed, respectively multiplied by χ_H, and they form a basis when $2 \neq 0$. (iii) Associativity of the tensor product, $k[G] \otimes_{k[K]} (k[K] \otimes_{k[H]} W) = k[G] \otimes_{k[H]} W$; additivity of $\otimes$; and $K \otimes_k (k[G] \otimes_{k[H]} W) = K[G] \otimes_{K[H]} W_K$. □

Theorem 4.42 (Mackey)**.** *Let $H \leq G$ have finite index and W a representation of H.*

(a) For $K \leq G$, $\operatorname{Res}_K \operatorname{Ind}_H^G W \simeq \bigoplus_{s \in K\backslash G/H} \operatorname{Ind}_{K \cap sHs^{-1}}^K \operatorname{Res}_{K \cap sHs^{-1}} W^s$, the sum over a set of representatives of the double cosets.

(b) (Mackey's irreducibility criterion.) Let G be finite and $k = \mathbb{C}$. Then $\operatorname{Ind}_H^G W$ is irreducible iff W is irreducible and, for every $s \in G\backslash H$, the representations W^s and W of $H_s = sHs^{-1} \cap H$ have no common irreducible constituent.

(c) (Index two, any characteristic.) Let $[G : H] = 2$, $s \in G \setminus H$, and W absolutely irreducible. Then $\operatorname{Res}_H \operatorname{Ind}_H^G W \simeq W \oplus W^s$, and $\operatorname{Ind}_H^G W$ is absolutely irreducible iff $W_{\bar{k}} \not\simeq W^s_{\bar{k}}$.

Proof. (a) We do not prove this; see [173, Section 7.3]. (The summand for the double coset KsH is the sum of the blocks $t \otimes W$ with t running over representatives of the cosets $tH \subseteq KsH$.) (c) The restriction is Proposition 4.39(i) with $s_1 = 1$, $s_2 = s$ (H is normal). Work over $\bar{k}$, which is allowed by Proposition 4.41(iii); W and W^s are irreducible. Suppose $W \not\simeq W^s$. The H-representation $W \oplus W^s$ is semisimple with non-isomorphic summands, so by Proposition 4.17(iii) its subrepresentations are 0, $W = 1 \otimes W$, $W^s = s \otimes W$ and the whole space (a subrepresentation U is semisimple, $U = \bigoplus_S U_S$, and each isotypic component U_S lies in the corresponding isotypic component of the whole space, which is the irreducible $1 \otimes W$ or $s \otimes W$). A nonzero G-stable subspace is H-stable and s-stable, and s exchanges $1 \otimes W$ and $s \otimes W$; so it is everything, and $\operatorname{Ind} W$ is irreducible over $\bar{k}$. Suppose $W \simeq W^s$. By Theorem 4.40(i) and Schur over $\bar{k}$, $\operatorname{End}_G(\operatorname{Ind} W) = \operatorname{Hom}_H(W, W \oplus W^s)$ has dimension 2; an irreducible representation over $\bar{k}$ has endomorphism ring $\bar{k}$ (Theorem 4.10(ii)), so $\operatorname{Ind} W$ is reducible. □

Sketch of proof of (b). By (i) of Theorem 4.40 and (a) with $K = H$,

$$\operatorname{End}_G(\operatorname{Ind} W) \simeq \operatorname{Hom}_H(W, \operatorname{Res}_H \operatorname{Ind} W) = \bigoplus_{s \in H\backslash G/H} \operatorname{Hom}_H(W, \operatorname{Ind}_{H_s}^H W^s),$$

and by Frobenius reciprocity again the summand for s is $\operatorname{Hom}_{H_s}(\operatorname{Res}_{H_s} W, W^s)$. The summand for $s = 1$ is $\operatorname{End}_H(W)$. In characteristic 0 all representations are semisimple, so $\operatorname{Ind} W$ is irreducible iff $\dim \operatorname{End}_G(\operatorname{Ind} W) = 1$, iff $\operatorname{End}_H(W) = \mathbb{C}$ (that is, W irreducible) and the other summands vanish. See [173, Section 7.4]. In characteristic p the criterion fails as stated, because $\operatorname{End}_G(V) = k$ does not force irreducibility without semisimplicity (Example 4.20(d)); only (c) is needed here. □

Theorem 4.43 (Clifford)**.** *Let $N \trianglelefteq G$ have finite index and V an irreducible representation of G over any field. Then $\operatorname{Res}_N V$ is semisimple, its irreducible constituents are the conjugates W^g ($g \in G$) of any one of them, and they all occur with the same multiplicity.*

Proof. Let $W \subseteq V$ be an irreducible N-subrepresentation (one of minimal positive dimension). For $g \in G$, gW is N-stable, since $n\,gW = g(g^{-1}ng)W = gW$, and $w \mapsto gw$ is an isomorphism $W^g \to gW$ of representations of N; so gW is irreducible. The sum $\sum_g gW$ is G-stable and nonzero, hence equal to V. So $\operatorname{Res}_N V$ is a sum of irreducibles of the form W^g, semisimple by Proposition 4.17, and every irreducible constituent is isomorphic to some W^g (Theorem 4.21). For an irreducible S of N, the element g maps the isotypic component V_S bijectively onto V_{S^g}, so $\dim V_S = \dim V_{S^g}$, and the multiplicities agree. □

Theorem 4.44 (Clifford theory for a subgroup of index 2)**.** *Let G be any group, $H \leq G$ of index 2, $s \in G \setminus H$, $\chi_H : G \to \{\pm 1\}$ the character with kernel H, k a field with $\operatorname{char} k \neq 2$, and V an absolutely irreducible representation of G over k of dimension n. Exactly one of the following holds.*

(A) $\operatorname{Res}_H V$ *is absolutely irreducible. Then $V \not\simeq V \otimes \chi_H$, and $\operatorname{Ind}_H^G \operatorname{Res}_H V \simeq V \oplus (V \otimes \chi_H)$.*

(B) $\operatorname{Res}_H V$ *is not absolutely irreducible. Then $n = 2d$, there is an absolutely irreducible representation W of H over $\bar{k}$ of dimension d with $W \not\simeq W^s$, $\operatorname{Res}_H V_{\bar{k}} \simeq W \oplus W^s$ and $V_{\bar{k}} \simeq \operatorname{Ind}_H^G W$, and $V \simeq V \otimes \chi_H$ over k.*

Hence $V \simeq V \otimes \chi_H$ iff (B) holds. In that case $\operatorname{Hom}_G(V, V \otimes \chi_H)$ is a line over k, spanned by an isomorphism ϕ with $\phi^2 \in k^\times$ and $\operatorname{tr} \phi = 0$, whose two eigenspaces over $\bar{k}$ are W and W^s. For $n = 2$, (B) holds iff $V_{\bar{k}} \simeq \operatorname{Ind}_H^G \psi$ for a character ψ of H with $\psi^s \neq \psi$.

Proof. (A) An isomorphism $\phi\colon V \to V \otimes \chi_H$ commutes with $\rho(H)$, so it is a scalar c (Theorem 4.10(iii) for $\operatorname{Res}_H V$). Then $c\rho(s) = \chi_H(s)\rho(s)c = -c\rho(s)$, so $2c = 0$ and $c = 0$, a contradiction. The induced statement is $\operatorname{Ind}_H^G \operatorname{Res}_H V \simeq V \otimes \operatorname{Ind}_H^G \mathbf{1} \simeq V \otimes (\mathbf{1} \oplus \chi_H)$ (Proposition 4.41(i), (ii)).

(B) $V_{\bar{k}}$ is irreducible and $\operatorname{Res}_H V_{\bar{k}}$ is reducible. By Theorem 4.43, $\operatorname{Res}_H V_{\bar{k}}$ is semisimple and its constituents are W and W^s for an irreducible W (absolutely irreducible, as $\bar{k}$ is algebraically closed), each of dimension d; being reducible, it has at least two constituents, so $n \geq 2d$. By Theorem 4.40(i) the inclusion $W \subseteq \operatorname{Res}_H V_{\bar{k}}$ gives a nonzero G-map $\operatorname{Ind}_H^G W \to V_{\bar{k}}$, surjective as $V_{\bar{k}}$ is irreducible; so $n \leq 2d$. Hence $n = 2d$ and the map is an isomorphism $\operatorname{Ind}_H^G W \simeq V_{\bar{k}}$. As $\operatorname{Ind} W$ is irreducible, $W \not\simeq W^s$ by Theorem 4.42(c), which also gives $\operatorname{Res}_H V_{\bar{k}} \simeq W \oplus W^s$. By

Proposition 4.41(i), $V_{\bar{k}} \otimes \chi_H \simeq \mathrm{Ind}_H^G(W \otimes \mathrm{Res}_H \chi_H) = \mathrm{Ind}_H^G W \simeq V_{\bar{k}}$, and since $V_{\bar{k}}$ is irreducible, Proposition 4.7(iii) gives $V \simeq V \otimes \chi_H$ over k.

The two cases are exclusive and exhaustive, so $V \simeq V \otimes \chi_H$ iff (B). In case (B), $V \otimes \chi_H$ is absolutely irreducible (Proposition 4.48(ii)), so $\mathrm{Hom}_G(V, V \otimes \chi_H)$ is a line (Theorem 4.10(iii)) spanned by an isomorphism ϕ. The composite $\phi \circ \phi$ is a G-isomorphism $V \to V \otimes \chi_H^2 = V$ (the linear map ϕ is also a G-map $V \otimes \chi_H \to V \otimes \chi_H^2$, by Proposition 4.48(ii)), hence a nonzero scalar (Theorem 4.10(iii)). By Lemma 4.49, $\mathrm{tr}\,\phi = 0$ ($\chi_H(s) = -1 \neq 1$). Over $\bar{k}$, ϕ commutes with H, so it preserves the isotypic components W and W^s of $\mathrm{Res}_H V_{\bar{k}}$ (Proposition 4.17(iii)) and acts on each by a scalar (Schur); the two scalars differ, since otherwise ϕ would be a scalar $c \neq 0$, and $c\rho(s) = \phi\rho(s) = \chi_H(s)\rho(s)\phi = -c\rho(s)$ would force $c = 0$, as in (A). For $n = 2$, $d = 1$ and $W = \psi$ is a character; conversely if $V_{\bar{k}} \simeq \mathrm{Ind}\,\psi$ then $\mathrm{Res}_H V_{\bar{k}} \simeq \psi \oplus \psi^s$ is reducible. □

A small example over $\mathbb{C}$: $G = S_3$, $H = A_3 = \langle r \rangle$ with r a 3-cycle, s a transposition, $\chi_H = \mathrm{sgn}$. The two-dimensional irreducible representation V of S_3 (the plane P of the example after Definition 4.2) restricts to A_3 as $\omega \oplus \omega^{-1}$, where $\omega(r) = e^{2\pi i/3}$: the permutation matrix of r has eigenvalues $1, e^{\pm 2\pi i/3}$ on $\mathbb{C}^3$, and the eigenvalue 1 belongs to D. Since $srs^{-1} = r^{-1}$, $\omega^s = \omega^{-1} \neq \omega$, so we are in case (B): $V \simeq \mathrm{Ind}_{A_3}^{S_3} \omega$ and $V \simeq V \otimes \mathrm{sgn}$. If v is an eigenvector of r for $\omega(r)$, then sv is one for $\omega(r)^{-1}$, and in the basis v, sv the intertwiner is $\phi = \mathrm{diag}(1, -1)$: it commutes with r, which is diagonal, and anticommutes with $s = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$; its trace is 0. The one-dimensional representations $\mathbf{1}$ and sgn are in case (A), and the twist by sgn exchanges them.

In the paper 4.45. Proposition prop:ns: "by Frobenius reciprocity $\bar{\rho} \otimes \mathbb{F}_9 \simeq \mathrm{Ind}\,\psi$, so $\bar{\rho} \simeq \bar{\rho} \otimes \chi_{-3}$". In the language above: $G = G_{\mathbb{Q}}$, $H = G_{\mathbb{Q}(\sqrt{-3})}$, $\chi_H = \chi_{-3}$; the eigenline of $\bar{\rho}(H) = C_4$ with character ψ (Example 4.14) is a nonzero H-map $\psi \to \mathrm{Res}_H(\bar{\rho} \otimes \mathbb{F}_9)$, which by Theorem 4.40(i) gives a nonzero G-map $\mathrm{Ind}_H^G \psi \to \bar{\rho} \otimes \mathbb{F}_9$, surjective because $\bar{\rho} \otimes \mathbb{F}_9$ is irreducible, hence an isomorphism (both have dimension 2). Then $\mathrm{Ind}\,\psi \otimes \chi_{-3} \simeq \mathrm{Ind}\,\psi$ (Proposition 4.41(i)), and the isomorphism descends to $\mathbb{F}_3$ (Proposition 4.7(ii)). The last equivalence of Lemma lem:h0 ($\bar{\rho} \simeq \bar{\rho} \otimes \chi_{-3}$ iff $\bar{\rho}$ is not absolutely irreducible on $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$) and the first sentence of the proof of Proposition prop:Sf (the same with χ_{ℓ^*}) are Theorem 4.44; it needs $\bar{\rho}$ absolutely irreducible, which complex conjugation provides (Proposition 4.13). The representation $\bar{\rho}$ is induced from H only after extending scalars: over $\mathbb{F}_3$, $\mathrm{Res}_H \bar{\rho}$ is irreducible (Proposition 4.63).

Proposition 4.46 (Dihedral representations)**.** *Let* $\mathrm{char}\, k \neq 2$ *and* $\rho\colon G \to \mathrm{GL}_2(k)$ *absolutely irreducible, with finite projective image* P*, the image of* G *in* $\mathrm{PGL}_2(\bar{k})$*.*

(i) P *is not cyclic.*

(ii) The following are equivalent: (a) P *is dihedral of order* $2m$ *for some* $m \geq 2$ *(for* $m = 2$*,* $P \simeq V_4$*); (b)* $\rho \simeq \rho \otimes \chi$ *for a character* χ *of order* 2*; (c)* $\rho_{\bar{k}} \simeq \mathrm{Ind}_H^G \psi$ *for a subgroup* H *of index* 2 *and a character* ψ *of* H*.*

(iii) The characters $\chi \neq 1$ *with* $\rho \simeq \rho \otimes \chi$ *correspond bijectively, by* $\chi \mapsto$ *the image of* $\ker \chi$ *in* P*, to the cyclic subgroups of index* 2 *of* P*: there is exactly one if* P *is dihedral of order at least* 6*, and there are three if* $P \simeq V_4$*.*

Proof. Let $Z = \rho^{-1}(\bar{k}^\times)$ be the preimage of the scalars, so $P = G/Z$. (i) If P is generated by the image of g_0, then $\rho(G) \subseteq \bar{k}^\times \langle \rho(g_0) \rangle$ is abelian, and ρ is absolutely reducible by Proposition 4.26(i). First a claim: *for* $H \leq G$ *of index* 2*,* $\mathrm{Res}_H \rho$ *is absolutely reducible iff the image of* H *in* P *is cyclic.* If the image is cyclic, $\rho(H)$ is abelian as in (i) and Proposition 4.26(i) applies. If $\mathrm{Res}_H \rho_{\bar{k}}$ has a stable line, then by Theorem 4.44(B) it is $\psi \oplus \psi^s$, so $\rho(H)$ is diagonal in a suitable basis,

and its image in $\mathrm{PGL}_2(\bar{k})$ is a finite subgroup of the group of classes of $\mathrm{diag}(x,1)$, which is isomorphic to $\bar{k}^\times$; finite subgroups of $\bar{k}^\times$ are cyclic. (ii) (b)$\Leftrightarrow$(c): a character of order 2 is χ_H for $H=\ker\chi$ of index 2, and Theorem 4.44 says that $\rho\simeq\rho\otimes\chi_H$ iff (B) holds for H, iff $\rho_{\bar{k}}$ is induced from a character of H. (c)$\Rightarrow$(a): in the basis of Proposition 4.39(iii), $\rho(H)$ is diagonal and $\rho(G\setminus H)$ antidiagonal. The image C of H in P is cyclic by the claim, since $\mathrm{Res}_H\,\rho_{\bar{k}}\simeq\psi\oplus\psi^s$ is reducible; it has index 1 or 2 in P; by (i), $P\neq C$. An antidiagonal matrix $\left(\begin{smallmatrix}0&a\\b&0\end{smallmatrix}\right)$ squares to the scalar ab, and conjugating $\mathrm{diag}(x,y)$ by it gives $\mathrm{diag}(y,x)$, which is the inverse of $\mathrm{diag}(x,y)$ modulo scalars. So $P=C\rtimes C_2$ with the involution inverting C, and $\#C=m\geq 2$ by (i): P is dihedral of order $2m$ (for $m=2$, V_4). (a)$\Rightarrow$(c): a dihedral group of order $2m$ has a cyclic subgroup of index 2 (for V_4, any subgroup of order 2); its preimage H in G has index 2 and cyclic image, so $\mathrm{Res}_H\,\rho$ is absolutely reducible by the claim, and Theorem 4.44(B) gives (c). (iii) If $\rho\simeq\rho\otimes\chi$ with $\chi\neq 1$, then $\chi^2=1$ (Proposition 4.48(iv)), so $\chi=\chi_H$ with $H=\ker\chi$ of index 2. For $z\in Z$, $\mathrm{tr}\,\rho(z)=\chi(z)\,\mathrm{tr}\,\rho(z)$ and $\mathrm{tr}\,\rho(z)=2c\neq 0$ for the scalar $c=\rho(z)$; so $\chi(z)=1$ and $Z\subseteq H$. Hence such H correspond to the subgroups of index 2 of P, and by the claim and Theorem 4.44 exactly those with cyclic image occur. In a dihedral group of order $2m$, $m\geq 3$, the only cyclic subgroup of index 2 is the rotation subgroup (the others, which exist for m even, are dihedral of order $m\geq 4$, hence not cyclic); V_4 has three subgroups of index 2, all cyclic. □

In the paper 4.47. Among irreducible $\bar{\rho}$ (a reducible one fails it trivially), the hypothesis of Theorem thm:main excludes exactly the representations induced from $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell^*}))$, not all dihedral ones (Remark 4.83(ii)). At $\ell=3$, the image $N_s(\mathbb{F}_3)$ has projective image V_4 and is induced in three ways, one of them from the determinant-one subgroup (Proposition 4.63); the image $N_{ns}(\mathbb{F}_3)$ has projective image D_4 and is induced only from $C_{ns}(\mathbb{F}_3)$, whose fixed field is not $\mathbb{Q}(\sqrt{-3})$ (Proposition 4.64), so it satisfies the hypothesis.

4.7 Twisting, the adjoint, the symmetric square and the trace form

This section treats the operations the paper performs on ρ: twisting by a character, passing to the adjoint $\mathrm{End}(V)$ and to its trace-zero part $\mathrm{ad}^0 V$, and the identification of $\mathrm{ad}^0 V$ with a twist of the symmetric square and with its own dual. In the paper, $A_f=\mathrm{ad}^0 V$ (Section 1.1), $A=\mathrm{ad}^0 T$ and $T^D=\mathrm{Hom}(A,\mathbb{Z}_\ell(1))\simeq A(1)$ (Section 4.2), $H^0(\mathbb{Q},W^D)$ is a space of trace-zero G-maps $\bar{\rho}\to\bar{\rho}\otimes\bar{\chi}_\ell$ (Lemma lem:h0), and the proof of Lemma lem:tamfactor computes the adjoint action of two triangular matrices in the basis e,h,f.

Proposition 4.48 (Twisting)**.** *Let V be a representation of G over k (or a free R-module) of rank n and $\chi\colon G\to k^\times$ (or $R^\times$) a character.*

(i) $\mathrm{tr}(\rho\otimes\chi)(g)=\chi(g)\,\mathrm{tr}\,\rho(g)$, $\det(X-(\rho\otimes\chi)(g))=\det(X-\chi(g)\rho(g))$ *and* $\det(\rho\otimes\chi)=\chi^n\det\rho$.

(ii) V is irreducible (absolutely irreducible) iff $V\otimes\chi$ is; $\mathrm{Hom}_G(V\otimes\chi,W\otimes\chi)=\mathrm{Hom}_G(V,W)$; $(V\otimes\chi)^\vee=V^\vee\otimes\chi^{-1}$; *and* $\mathrm{Res}_{\ker\chi}(V\otimes\chi)=\mathrm{Res}_{\ker\chi}V$.

(iii) $\mathrm{End}(V\otimes\chi)=\mathrm{End}(V)$ *as representations (the same space with the same action), hence* $\mathrm{ad}^0(V\otimes\chi)=\mathrm{ad}^0 V$.

(iv) If $V\simeq V\otimes\chi$, then $\chi^n=1$ on G; for $n=2$, $\chi^2=1$.

Proof. On the space V the twist acts by $\chi(g)\rho(g)$; this gives (i) and the last statement of (ii). The G-stable subspaces of V and of $V\otimes\chi$ coincide (a scalar preserves every subspace), also after extending scalars. A linear map ϕ satisfies $\phi\,\chi(g)\rho_V(g)=\chi(g)\rho_W(g)\phi$ iff $\phi\rho_V(g)=\rho_W(g)\phi$. The dual of $\chi(g)\rho(g)$ is $\chi(g)^{-1}\rho(g^{-1})^t$. (iii) $(\chi(g)\rho(g))x(\chi(g)\rho(g))^{-1}=\rho(g)x\rho(g)^{-1}$. (iv) An isomorphism $V\to V\otimes\chi$ is an invertible P with $P\rho(g)P^{-1}=\chi(g)\rho(g)$ for all g. Taking determinants, $\det\rho(g)=\chi(g)^n\det\rho(g)$, and $\det\rho(g)$ is a unit, so $\chi(g)^n=1$. (Equivalently: $\det(V\otimes\chi)=\chi^n\det V$ by (i), and isomorphic representations have the same determinant.) □

Lemma 4.49 (The trace-zero lemma)**.** *Let $\phi\colon V\to V\otimes\chi$ be a G-map, that is, $\phi\rho(g)=\chi(g)\rho(g)\phi$ for all $g\in G$. Then $(1-\chi(g))\operatorname{tr}\phi=0$ for every $g\in G$. Hence $\operatorname{tr}\phi=0$ if $\chi\neq 1$ (over a field), or, over a ring R, if $1-\chi(g)\in R^\times$ for some g. If moreover V is absolutely irreducible, $\operatorname{Hom}_G(V,V\otimes\chi)$ has dimension at most 1, and its nonzero elements are isomorphisms.*

Proof. $\operatorname{tr}\phi=\operatorname{tr}(\rho(g)^{-1}\phi\rho(g))=\operatorname{tr}(\rho(g)^{-1}\chi(g)\rho(g)\phi)=\chi(g)\operatorname{tr}\phi$. The last statement is Theorem 4.10(iii) for the absolutely irreducible representations V and $V\otimes\chi$ (Proposition 4.48(ii)). □

In the paper 4.50. Lemma lem:h0: "every such map has trace 0 automatically, since $\operatorname{tr}\phi=\chi_\ell(g)\operatorname{tr}\phi$ for every g and $1-\chi_\ell(c)=2$ is a unit for complex conjugation c" is Lemma 4.49 over $R=\mathbb{Z}/\ell^k$, ℓ odd. "Taking determinants" (the step $\chi_\ell^2\equiv 1$) is Proposition 4.48(iv) modulo ℓ^k (see Proposition 4.81(v)). "ad^0T is unchanged by the twist" (proofs of Theorems thm:main and thm:quant, Lemma lem:tamfactor at an additive potentially multiplicative prime, Lemma lem:euler for I_n^*, I_0^*) is (iii).

Definition 4.51. The *adjoint representation* of V is $\operatorname{End}(V)=V\otimes V^\vee$ with $g\cdot x=\rho(g)x\rho(g)^{-1}$, also written $\operatorname{Ad}V$ or $\operatorname{Ad}\rho$; the *trace-zero adjoint* is $\mathrm{ad}^0V=\{x\in\operatorname{End}(V):\operatorname{tr}x=0\}$, a subrepresentation since the trace is conjugation invariant. The paper writes $A_f=\mathrm{ad}^0V$ for $V=V_\ell E$ and $A=\mathrm{ad}^0T$ for $T=T_\ell E$.

The adjoint enters number theory because it governs the deformations of ρ. If $k[\epsilon]=k[X]/(X^2)$ and $\rho_\epsilon\colon G\to\mathrm{GL}_n(k[\epsilon])$ reduces to ρ modulo ϵ, write $\rho_\epsilon(g)=(1+\epsilon c(g))\rho(g)$ with $c(g)\in\operatorname{End}(V)$. Since $\epsilon^2=0$,

$$\rho_\epsilon(g)\rho_\epsilon(h)=\big(1+\epsilon(c(g)+\rho(g)c(h)\rho(g)^{-1})\big)\rho(gh),$$

so ρ_ϵ is a homomorphism iff $c(gh)=c(g)+g\cdot c(h)$ for the adjoint action: c is a 1-cocycle with values in $\operatorname{End}(V)$. As $\det(1+\epsilon c)=1+\epsilon\operatorname{tr}c$, the deformations with unchanged determinant correspond to cocycles with values in ad^0V. This is the origin of the Selmer groups of ad^0V studied in Chapter 18. A first example of the representation itself: if $\rho=\eta_1\oplus\eta_2$ is diagonal, conjugation by $\operatorname{diag}(\eta_1(g),\eta_2(g))$ multiplies e by $\eta_1(g)/\eta_2(g)$, fixes h and multiplies f by $\eta_2(g)/\eta_1(g)$ (Proposition 4.52(iii)), so $\mathrm{ad}^0V\simeq\eta_1\eta_2^{-1}\oplus\mathbf{1}\oplus\eta_2\eta_1^{-1}$.

Proposition 4.52. *Let V be a representation of G over k (or a free R-module) of rank n.*

(i) If n is invertible in k (or R), $\operatorname{End}(V)=k\cdot 1\oplus\mathrm{ad}^0V$ as representations, $x=\frac{\operatorname{tr}x}{n}\cdot 1+(x-\frac{\operatorname{tr}x}{n}\cdot 1)$. For $n=2$ this needs $\operatorname{char}k\neq 2$, that is, ℓ odd.

(ii) If $\rho(g)$ has eigenvalues $\lambda_1,\dots,\lambda_n$ in $\bar{k}$ (with multiplicity), then $\operatorname{Ad}\rho(g)$ has the eigenvalues λ_i/λ_j on $\operatorname{End}(V)$. For $n=2$ it has the eigenvalues λ_1/λ_2, 1, λ_2/λ_1 on ad^0V, in every characteristic, and $\det(X-\operatorname{Ad}\rho(g)\mid\mathrm{ad}^0V)=(X-1)(X^2-(\operatorname{tr}(g)^2/\det(g)-2)X+1)$.

(iii) In the basis e, h, f of $\mathrm{ad}^0 V$ (convention (C3)):

$$\begin{aligned}
&\mathrm{Ad}\,\mathrm{diag}(x,y): \quad e \mapsto \tfrac{x}{y}\,e, \quad h \mapsto h, \quad f \mapsto \tfrac{y}{x}\,f;\\
&t = \begin{pmatrix} 1 & n' \\ 0 & 1 \end{pmatrix}: \quad (t-1)e = 0, \quad (t-1)h = -2n'e, \quad (t-1)f = n'h - n'^2 e;\\
&F = \begin{pmatrix} \varepsilon q & c' \\ 0 & \varepsilon \end{pmatrix}: \quad FeF^{-1} = qe, \quad FhF^{-1} = h - 2c'\varepsilon^{-1}e,\\
&\qquad\qquad FfF^{-1} = q^{-1}f + c'\varepsilon^{-1}q^{-1}h - c'^2\varepsilon^{-2}q^{-1}e,
\end{aligned}$$

for $x, y, \varepsilon \in R^\times$, $q \in R^\times$, $n', c' \in R$. In the paper $\varepsilon = \pm 1$ is the value at Frobenius of the unramified character of the Tate data (convention B-C14), so $\varepsilon^{-1} = \varepsilon$.

Proof. (i) The map $x \mapsto \frac{\mathrm{tr}\,x}{n} \cdot 1$ is a projection onto the scalars with kernel $\mathrm{ad}^0 V$, and it is G-equivariant because $\mathrm{tr}(gxg^{-1}) = \mathrm{tr}\,x$ and $g1g^{-1} = 1$; so both summands are subrepresentations. (ii) Over $\bar{k}$, conjugate $\rho(g)$ to an upper triangular matrix with diagonal $\lambda_1, \dots, \lambda_n$. On $V^\vee$, g acts by $\rho(g^{-1})^t$, with eigenvalues λ_j^{-1}, and the eigenvalues on $V \otimes V^\vee$ are the products (triangularise both factors). For $n = 2$ and $g = \left(\begin{smallmatrix} \lambda_1 & b \\ 0 & \lambda_2 \end{smallmatrix}\right)$, the matrix of $\mathrm{Ad}\,g$ in the ordered basis e, h, f is upper triangular with diagonal $\lambda_1/\lambda_2, 1, \lambda_2/\lambda_1$: $geg^{-1} = \frac{\lambda_1}{\lambda_2}e$, $ghg^{-1} \in h + ke$ and $gfg^{-1} \in \frac{\lambda_2}{\lambda_1}f + kh + ke$, as the formulas of (iii) for F show (with $\varepsilon q = \lambda_1$, $\varepsilon = \lambda_2$). The factor $X^2 - (\mathrm{tr}(g)^2/\det(g) - 2)X + 1$ has roots λ_1/λ_2, λ_2/λ_1, since their sum is $(\lambda_1^2 + \lambda_2^2)/\lambda_1\lambda_2$. (iii) Here $(t-1)x$ means $t \cdot x - x = txt^{-1} - x$, the adjoint action minus the identity, not the matrix product of $t - 1$ and x: the matrix product $(t-1)h$ is $\left(\begin{smallmatrix} 0 & -n' \\ 0 & 0 \end{smallmatrix}\right) = -n'e$, while $tht^{-1} - h = -2n'e$. The formulas follow by direct multiplication. For instance $th = \left(\begin{smallmatrix} 1 & -n' \\ 0 & -1 \end{smallmatrix}\right)$, so $tht^{-1} = \left(\begin{smallmatrix} 1 & -n' \\ 0 & -1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & -n' \\ 0 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & -2n' \\ 0 & -1 \end{smallmatrix}\right) = h - 2n'e$; and $tf = \left(\begin{smallmatrix} n' & 0 \\ 1 & 0 \end{smallmatrix}\right)$, $tft^{-1} = \left(\begin{smallmatrix} n' & -n'^2 \\ 1 & -n' \end{smallmatrix}\right) = f + n'h - n'^2 e$. With $F^{-1} = \frac{1}{\varepsilon^2 q}\left(\begin{smallmatrix} \varepsilon & -c' \\ 0 & \varepsilon q \end{smallmatrix}\right)$: $Fe = \left(\begin{smallmatrix} 0 & \varepsilon q \\ 0 & 0 \end{smallmatrix}\right)$ and $FeF^{-1} = qe$; $Fh = \left(\begin{smallmatrix} \varepsilon q & -c' \\ 0 & -\varepsilon \end{smallmatrix}\right)$ and $FhF^{-1} = \frac{1}{\varepsilon^2 q}\left(\begin{smallmatrix} \varepsilon^2 q & -2\varepsilon q c' \\ 0 & -\varepsilon^2 q \end{smallmatrix}\right) = h - 2c'\varepsilon^{-1}e$; $Ff = \left(\begin{smallmatrix} c' & 0 \\ \varepsilon & 0 \end{smallmatrix}\right)$ and $FfF^{-1} = \frac{1}{\varepsilon^2 q}\left(\begin{smallmatrix} \varepsilon c' & -c'^2 \\ \varepsilon^2 & -\varepsilon c' \end{smallmatrix}\right)$, which is the stated combination. These identities were also checked symbolically. □

In the paper 4.53. Section 1.1: $A_f = \mathrm{ad}^0 V$, and at a good prime the Frobenius has the eigenvalues $\alpha/\beta, 1, \beta/\alpha$ on $\mathrm{ad}^0 V$ by (ii), for either Frobenius (the set is stable under inversion; convention B-C3), which gives the good factor of $L(A_f, s)$ (Chapter 19). Lemma lem:tamfactor: "$(t-1)e = 0$, $(t-1)h = -2n'e$, $(t-1)f = n'h - n'^2 e$, and as 2 is a unit, $(t-1)M = n'(\mathbb{Z}_\ell e \oplus \mathbb{Z}_\ell h)$", and "the adjoint action sends e to qe and h to $h - 2c'\varepsilon e$", are (iii) with $\varepsilon^{-1} = \varepsilon$; $F = \rho(\mathrm{Frob})$ there is the arithmetic Frobenius (convention B-C2(c)). The cohomology built on these formulas is in Chapter 16.

Proposition 4.54 (Invariants of twisted adjoints)**.** *Let V be a representation over k, or a free module of rank n over a local ring R, and χ a character.*

(i) $(\mathrm{End}(V) \otimes \chi)^G = \mathrm{Hom}_G(V, V \otimes \chi)$.

(ii) If n is invertible, $(\mathrm{End}(V) \otimes \chi)^G = (\mathrm{ad}^0 V \otimes \chi)^G \oplus R(\chi)^G$, *and* $(\mathrm{ad}^0 V \otimes \chi)^G = \{\phi \in \mathrm{Hom}_G(V, V \otimes \chi) : \mathrm{tr}\,\phi = 0\}$.

(iii) *If $\chi \neq 1$ (over a local ring R: if the reduction $\bar\chi$ of χ modulo the maximal ideal is nontrivial), then $R(\chi)^G = 0$, every G-map $V \to V \otimes \chi$ has trace 0, and $(\mathrm{ad}^0 V \otimes \chi)^G = \mathrm{Hom}_G(V, V \otimes \chi)$.*

(iv) *If V is absolutely irreducible over k and $n \in k^\times$, then $(\mathrm{ad}^0 V)^G = 0$; and for $\chi \neq 1$, $(\mathrm{ad}^0 V \otimes \chi)^G \neq 0$ iff $V \simeq V \otimes \chi$, in which case it is a line spanned by an isomorphism.*

Proof. (i) is Proposition 4.5. (ii) Twist the decomposition of Proposition 4.52(i) by χ and take invariants. (iii) If $\bar\chi(g) \neq 1$ then $\chi(g) - 1$ is a unit, and $\chi(g)x = x$ forces $x = 0$; the rest is Lemma 4.49 and (ii). (iv) $\mathrm{End}_G(V) = k$, and a scalar c has trace nc, which vanishes only for $c = 0$. For $\chi \neq 1$, by (iii) $(\mathrm{ad}^0 V \otimes \chi)^G = \mathrm{Hom}_G(V, V \otimes \chi)$, which is described by Lemma 4.49. □

In the paper 4.55. Lemma lem:h0, case $k = 1$ of the sentence quoted after Proposition 4.5: the ℓ-torsion of $H^0(\mathbb{Q}, W^D)$ is $H^0(\mathbb{Q}, \mathrm{ad}^0\,\bar\rho \otimes \bar\chi_\ell)$, the space of trace-zero $G_\mathbb{Q}$-maps $\bar\rho \to \bar\rho \otimes \bar\chi_\ell$; by (iii) the trace condition is automatic because $\bar\chi_\ell \neq 1$ for ℓ odd. Proposition prop:ns: "$H^0(\mathbb{Q}, \mathrm{ad}^0\,\bar\rho_{E,3}(1)) \neq 0$" is (iv) with $\chi = \bar\chi_3 = \chi_{-3}$ and the isomorphism $\bar\rho \simeq \bar\rho \otimes \chi_{-3}$.

Proposition 4.56 (Adjoint and symmetric square)**.** *Let V be free of rank 2 over R with basis e_1, e_2, $\omega(x, y) = \det[x \,|\, y]$, and let $\mathrm{Sym}^2 V$ be the quotient of $V \otimes V$ by the span of the $x \otimes y - y \otimes x$, with basis e_1^2, e_1e_2, e_2^2. If $\rho(g)$ has eigenvalues λ, μ, then $\mathrm{Sym}^2 \rho(g)$ has eigenvalues $\lambda^2, \lambda\mu, \mu^2$.*

(i) *The map $\Xi\colon \mathrm{Sym}^2 V \to \mathrm{End}(V)$, $\Xi(xy)(v) = \omega(v, x)y + \omega(v, y)x$, is well defined, takes values in $\mathrm{ad}^0 V$, and satisfies $\Xi(g\cdot m) = \det(g)\,\rho(g)\Xi(m)\rho(g)^{-1}$. So Ξ is a G-map $\mathrm{Sym}^2 V \otimes \det^{-1} \to \mathrm{ad}^0 V$. In coordinates*

$$\Xi(e_1^2) = -2e, \qquad \Xi(e_1e_2) = h, \qquad \Xi(e_2^2) = 2f,$$

so Ξ is an isomorphism iff $2 \in R^\times$; over $\mathbb{Z}$ its image has index 4 in $\mathrm{ad}^0 \mathbb{Z}^2$, and over $\mathbb{Z}_\ell$ it is an isomorphism of lattices iff ℓ is odd.

(ii) *Hence, if $2 \in R^\times$, $\mathrm{ad}^0 \rho \simeq \mathrm{Sym}^2 \rho \otimes \det^{-1}$ and $\mathrm{Sym}^2 \rho \simeq \mathrm{ad}^0 \rho \otimes \det$; moreover $V \otimes V \simeq \mathrm{Sym}^2 V \oplus \det$ and $V \otimes V^\vee \simeq \mathrm{ad}^0 V \oplus \mathbf{1}$.*

(iii) *(Normalisations.) Let $V = V_\ell E$, with $\det = \chi_\ell$ (Chapter 9). Then $\mathrm{Sym}^2 V \simeq \mathrm{ad}^0 V(1)$ and $\mathrm{Sym}^2(V^\vee) \simeq \mathrm{ad}^0 V(-1)$. The classical symmetric square L-function is that of $\mathrm{Sym}^2(V^\vee) = \mathrm{Sym}^2 H^1$, so with the convention $L_p(M(n), s) = L_p(M, s + n)$ (B-C2(d)), $L_p(\mathrm{Sym}^2 f, s) = L_p(A_f, s - 1)$.*

Proof. The eigenvalue statement follows by triangularising $\rho(g)$: in the basis e_1^2, e_1e_2, e_2^2 the matrix of $\mathrm{Sym}^2 \rho(g)$ is then triangular with diagonal $\lambda^2, \lambda\mu, \mu^2$. (i) The expression is bilinear and symmetric in (x, y), so it factors through $\mathrm{Sym}^2 V$. The trace of $v \mapsto \lambda(v)y$ is $\lambda(y)$, so $\mathrm{tr}\,\Xi(xy) = \omega(y, x) + \omega(x, y) = 0$. Using $\omega(v, gx) = \det(g)\omega(g^{-1}v, x)$ (Proposition 4.4(iii)),

$$\Xi(gx\,gy)(v) = \det(g)(\omega(g^{-1}v, x)gy + \omega(g^{-1}v, y)gx) = \det(g)\,\rho(g)\Xi(xy)\rho(g)^{-1}(v).$$

In coordinates, $\omega(v, e_1) = -v_2$ and $\omega(v, e_2) = v_1$ for $v = v_1e_1 + v_2e_2$, so $\Xi(e_1^2)(v) = -2v_2e_1$, $\Xi(e_1e_2)(v) = v_1e_1 - v_2e_2$ and $\Xi(e_2^2)(v) = 2v_1e_2$, which are $-2e$, h, $2f$. The matrix of Ξ in these bases is $\mathrm{diag}(-2, 1, 2)$, of determinant -4. (ii) The first two statements are (i). For the others, $x \otimes y \mapsto (xy,\ \omega(x, y))$ is a G-map $V \otimes V \to \mathrm{Sym}^2 V \oplus \det$, bijective when $2 \in R^\times$ (inverse $(xy, c) \mapsto \frac{1}{2}(x \otimes y + y \otimes x) + \frac{c}{2}(e_1 \otimes e_2 - e_2 \otimes e_1)$); and $V \otimes V^\vee = \mathrm{End}(V) = \mathrm{ad}^0 V \oplus \mathbf{1}$ by Proposition 4.52(i). (iii) $\mathrm{Sym}^2 V \simeq \mathrm{ad}^0 V \otimes \det = \mathrm{ad}^0 V(1)$ by (ii). By Proposition 4.4(iii), $V^\vee \simeq V \otimes \chi_\ell^{-1} = V(-1)$, so $\mathrm{Sym}^2(V^\vee) \simeq \mathrm{Sym}^2 V(-2) \simeq \mathrm{ad}^0 V(-1)$. Then $L_p(\mathrm{Sym}^2(V^\vee), s) = L_p(\mathrm{ad}^0 V(-1), s) = L_p(\mathrm{ad}^0 V, s - 1)$; the definitions of the local factors are in Chapter 19 (convention B-C7). □

In the paper 4.57. Section 1.1: "In the normalisation of the symmetric square, $L_p(\mathrm{Sym}^2 f, s) = L_p(A_f, s-1)$" is (iii); the Introduction's comparison of Flach's theorem on $\mathrm{Sym}^2 f$ with the adjoint uses (ii). Over $\mathbb{Z}_2$ the map Ξ is not an isomorphism, one of the places where ℓ odd is needed for lattice-level statements.

Proposition 4.58 (The trace form)**.** *Let T be free of rank n over a commutative ring R, with an action of G.*

(i) $B(x,y) = \mathrm{tr}(xy)$ *on* $\mathrm{End}_R(T)$ *is G-invariant,* $B(gxg^{-1}, gyg^{-1}) = B(x,y)$*, and perfect:* $B(E_{ij}, E_{kl}) = \delta_{jk}\delta_{il}$*, a permutation Gram matrix, of determinant* ± 1*.*

(ii) For $n = 2$ the Gram matrix of B on $\mathrm{ad}^0 T$ in the basis e, h, f is $\left(\begin{smallmatrix} 0 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 0 \end{smallmatrix}\right)$*, of determinant -2, so B is perfect on $\mathrm{ad}^0 T$ iff $2 \in R^\times$.*

(iii) Let $R = \mathbb{Z}_\ell$ with ℓ odd and $A = \mathrm{ad}^0 T$. Then $x \mapsto B(x, -)$ is a G-isomorphism $A \simeq A^\vee = \mathrm{Hom}_{\mathbb{Z}_\ell}(A, \mathbb{Z}_\ell)$, and for every character $\chi\colon G \to \mathbb{Z}_\ell^\times$, $\mathrm{Hom}_{\mathbb{Z}_\ell}(A, \mathbb{Z}_\ell(\chi)) \simeq A(\chi)$; the same holds with $\mathbb{Q}_\ell$ or $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ in place of $\mathbb{Z}_\ell$. For $\ell = 2$ the image of A in $A^\vee$ has index 2.

Proof. (i) $\mathrm{tr}(gxg^{-1}gyg^{-1}) = \mathrm{tr}(gxyg^{-1}) = \mathrm{tr}(xy)$; and $E_{ij}E_{kl} = \delta_{jk}E_{il}$ has trace $\delta_{jk}\delta_{il}$. (ii) $e^2 = f^2 = 0$, $eh = -e$, $he = e$, $hf = -f$, so $\mathrm{tr}(e^2) = \mathrm{tr}(f^2) = \mathrm{tr}(eh) = \mathrm{tr}(hf) = 0$, while $\mathrm{tr}(ef) = \mathrm{tr}(E_{11}) = 1$ and $\mathrm{tr}(h^2) = 2$. A bilinear form on a free module of finite rank is perfect iff its Gram determinant is a unit (Chapter 3). (iii) By (ii) the map is an isomorphism; it is equivariant because $B(g \cdot x, y) = \mathrm{tr}(gxg^{-1}y) = \mathrm{tr}(x\, g^{-1}yg) = B(x, g^{-1} \cdot y)$ for the conjugation action, which says $B(gx, -) = g \cdot B(x, -)$ in $A^\vee$. Twisting by χ gives $\mathrm{Hom}(A, \mathbb{Z}_\ell(\chi)) = A^\vee(\chi) \simeq A(\chi)$; tensor with $\mathbb{Q}_\ell$ or $\mathbb{Q}_\ell/\mathbb{Z}_\ell$ for the other coefficients. For $\ell = 2$ the cokernel of the Gram matrix has order $|\det|_2^{-1} = 2$. □

In the paper 4.59. Section 4.2: "$T^D = \mathrm{Hom}(A, \mathbb{Z}_\ell(1)) \simeq A(1)$ (via the trace form)" is (iii) with $\chi = \chi_\ell$; it is one of the places where ℓ odd is used. Then $V^D = A(1) \otimes \mathbb{Q}_\ell$ and $W^D = \mathrm{ad}^0 T(1) \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$, the module of Lemma lem:h0 and Lemma lem:dfg21 (Chapter 18).

Proposition 4.60 (Invariance of the adjoint)**.** *Let V be a representation of G over a field and χ a character of G.*

(i) Twisting does not change the adjoint: $\mathrm{End}(V \otimes \chi)$ *is* $\mathrm{End}(V)$*, and* $\mathrm{ad}^0(V \otimes \chi)$ *is* $\mathrm{ad}^0 V$*, by Proposition 4.48(iii).*

(ii) The transpose $x \mapsto x^t$, where $x^t(\lambda) = \lambda \circ x$, is a G-isomorphism $\mathrm{End}(V) \to \mathrm{End}(V^\vee)$ *preserving traces, so it restricts to a G-isomorphism* $\mathrm{ad}^0 V \simeq \mathrm{ad}^0(V^\vee)$*; the map $x \mapsto -x^t$ has the same properties and also respects commutators.*

(iii) Let $L \subseteq V$ be an $\mathcal{O}$-lattice in a K-vector space, and put $\mathrm{ad}^0 L = \mathrm{End}_{\mathcal{O}}(L) \cap \mathrm{ad}^0 V$*. For $c \in K^\times$,* $\mathrm{End}_{\mathcal{O}}(cL) = \mathrm{End}_{\mathcal{O}}(L)$ *and* $\mathrm{ad}^0(cL) = \mathrm{ad}^0 L$ *inside* $\mathrm{End}_K(V)$*. For $L^\vee = \mathrm{Hom}_{\mathcal{O}}(L, \mathcal{O}) \subseteq V^\vee$, the transpose maps* $\mathrm{End}_{\mathcal{O}}(L)$ *onto* $\mathrm{End}_{\mathcal{O}}(L^\vee)$ *and* $\mathrm{ad}^0 L$ *onto* $\mathrm{ad}^0(L^\vee)$*.*

(iv) Consequently, if L' is a stable lattice homothetic to L, to $L^\vee$, or to a twist $L \otimes \mathcal{O}(\chi)$, then $\mathrm{ad}^0 L'$ *is canonically isomorphic to* $\mathrm{ad}^0 L$ *as a representation.*

Proof. (ii) On $V^\vee$, g acts by $\rho^\vee(g) = \rho(g^{-1})^t$. Then

$$(\rho(g)x\rho(g)^{-1})^t = \rho(g)^{-t}x^t\rho(g)^t = \rho^\vee(g)x^t\rho^\vee(g)^{-1},$$

and $\mathrm{tr}(x^t) = \mathrm{tr}\, x$. Also $[x,y]^t = -[x^t, y^t]$, so $-x^t$ respects commutators. (iii) $x(cL) \subseteq cL$ iff $xL \subseteq L$. A K-linear x preserves L iff x^t preserves $L^\vee$, because $L = (L^\vee)^\vee$ (both are free and dual bases correspond). (iv) Combine (i) to (iii); a twist does not change the underlying module. □

In the paper 4.61. Section 4.2: the lattice $M_{f,\lambda}$ of DFG04 is identified by φ_E^* with $H^1(E, \mathbb{Z}_\ell) = \mathrm{Hom}(T_\ell E, \mathbb{Z}_\ell) \simeq T_\ell E(-1)$ (Proposition prop:pullback; convention B-C5(b)), "so its adjoint is $\mathrm{ad}^0 T$": this is (ii) and (i), with no irreducibility needed. When $\bar\rho$ is irreducible there is a second route: $M_{f,\lambda}$ is homothetic to the dual $T_\ell E^\vee$ (Theorem 4.77), and then (iv) identifies the adjoints. Theorem thm:quant, Step 3 ("$A_g = A_f$" for a twist) is (i).

4.8 $\mathrm{GL}_2(\mathbb{F}_3)$ and its subgroups on $\mathbb{F}_3^2$ and $\mathbb{F}_9^2$

This section applies the theory to the standard representations of the subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$ that occur as mod 3 images. It is the representation-theoretic core of the paper's Proposition prop:ns: for the three possible images $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$, $N_s(\mathbb{F}_3)$ of an irreducible $\bar\rho_{E,3}$, the restriction to the determinant-one subgroup (the image of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$) is absolutely irreducible except for $N_s(\mathbb{F}_3)$, where it is $\psi \oplus \psi^{-1}$ over $\mathbb{F}_9$ and the representation is isomorphic to its twist by det (Theorem 4.66). The group theory (subgroups, orders, orbits on lines, the three images) is Chapter 1's; only the representation-theoretic reading is added here. Throughout, ρ is the standard representation (the inclusion $H \subseteq \mathrm{GL}_2(\mathbb{F}_3)$), and since det takes values in $\{\pm 1\}$, $\rho \otimes \det$ is the twist by the character $\det|_H$.

Proposition 4.62 (The standard representations of the subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$)**.** *For the standard models, the standard representation ρ of H on $\mathbb{F}_3^2$ has the following properties. In the first table, "irr." means irreducible over $\mathbb{F}_3$, "abs." absolutely irreducible, and the last column is the image of H in $\mathrm{PGL}_2(\mathbb{F}_3) \simeq S_4$.*

H	*order*	det *onto* $\mathbb{F}_3^\times$	*irr.*	*abs.*	# *of* $H/(H \cap \{\pm 1\})$	*projective image*
$\mathrm{GL}_2(\mathbb{F}_3)$	48	*yes*	*yes*	*yes*	24	S_4
$\mathrm{SL}_2(\mathbb{F}_3)$	24	*no*	*yes*	*yes*	12	A_4
$N_{ns}(\mathbb{F}_3)$	16	*yes*	*yes*	*yes*	8	D_4
Q_8	8	*no*	*yes*	*yes*	4	V_4 *(normal in* S_4*)*
$N_s(\mathbb{F}_3)$	8	*yes*	*yes*	*yes*	4	V_4 *(not normal)*
$C_{ns}(\mathbb{F}_3)$	8	*yes*	*yes*	*no*	4	C_4
$C_4 = \langle J \rangle$	4	*no*	*yes*	*no*	2	C_2
$C_s(\mathbb{F}_3)$	4	*yes*	*no*	*no*	2	C_2
$\mathrm{B}(\mathbb{F}_3)$	12	*yes*	*no*	*no*	6	S_3
U	3	*no*	*no*	*no*	3	C_3

In the second table, Hom *is* $\mathrm{Hom}_H(\rho, \rho \otimes \det)$*, with the dimension of its trace-zero part in parentheses, and the last column says whether* $\rho \simeq \rho \otimes \det$ *("triv." when* $\det|_H = 1$*, so that the question is empty).*

H	$\dim \mathrm{End}_H(\rho)$	$\dim(\mathrm{ad}^0\,\rho)^H$	$\dim \mathrm{Hom}$	$\rho \simeq \rho \otimes \det$	*trace-zero part*
$\mathrm{GL}_2(\mathbb{F}_3)$	1	0	0 (0)	*no*	
$\mathrm{SL}_2(\mathbb{F}_3)$	1	0	1 (0)	*triv.*	
$N_{ns}(\mathbb{F}_3)$	1	0	0 (0)	*no*	
Q_8	1	0	1 (0)	*triv.*	
$N_s(\mathbb{F}_3)$	1	0	1 (1)	***yes***	J
$C_{ns}(\mathbb{F}_3)$	2	1	0 (0)	*no*	
C_4	2	1	2 (1)	*triv.*	J
$C_s(\mathbb{F}_3)$	2	1	2 (2)	*yes*	w, $J = \sigma w$
$\mathrm{B}(\mathbb{F}_3)$	1	0	1 (1)	*no*	e *(not invertible)*
U	2	1	2 (1)	*triv.*	$e = u - 1$

Proof. Orders, surjectivity of det and the stable lines over $\mathbb{F}_3$ (hence the column "irr.") are in Chapter 1. Absolute irreducibility is Proposition 4.26(iv). The order of $H/(H \cap \{\pm 1\})$ is $\#H/2$ when $-1 \in H$, which is the case for all rows but U; the identifications $\mathrm{PGL}_2(\mathbb{F}_3) \simeq S_4$, $\mathrm{PSL}_2(\mathbb{F}_3) \simeq A_4$ and of the smaller images are in Chapter 1 (a non-abelian group of order 6 is S_3; $N_{ns}(\mathbb{F}_3)/\{\pm 1\}$ is non-abelian of order 8 with a cyclic subgroup $C_{ns}/\{\pm 1\}$ of order 4 and the involution σ outside it, so it is D_4). For the second table: in the absolutely irreducible rows $\mathrm{End}_H = \mathbb{F}_3$ (Theorem 4.10(iii)); for the cyclic groups $C_{ns} = \langle a \rangle$, $C_4 = \langle J \rangle$, $\mathrm{U} = \langle u \rangle$ the commutant of the non-scalar generator is 2-dimensional (Lemma 4.70); for C_s it is the diagonal matrices (the commutant of σ); for B it is $\mathbb{F}_3$ (Example 4.20(d)). As $2 \in \mathbb{F}_3^\times$, $\dim(\mathrm{ad}^0\,\rho)^H = \dim \mathrm{End}_H - 1$ (Proposition 4.52(i)). When $\det|_H = 1$, $\mathrm{Hom} = \mathrm{End}_H$ and its trace-zero part is $(\mathrm{ad}^0\,\rho)^H$; for the cyclic groups C_4 and U the commutant is $\{\alpha + \beta g\}$ and its trace-zero part is spanned by $2g - \mathrm{tr}\, g$ (Lemma 4.70(ii)), which is $2J = -J$ for $g = J$ and $2u - 2 = -(u-1)$ for $g = u$, giving the last column. When $\det|_H \neq 1$, every element of Hom has trace 0 (Lemma 4.49). For $\mathrm{GL}_2(\mathbb{F}_3)$ and $N_{ns}(\mathbb{F}_3)$, $\mathrm{Hom} = 0$ by Proposition 4.65 and Proposition 4.64; for $N_s(\mathbb{F}_3)$ it is $\mathbb{F}_3 J$ by Proposition 4.63. For C_{ns}: if $\phi a = -a\phi$ with $\phi \neq 0$, then $\ker \phi$ is a-stable, hence 0 (C_{ns} is irreducible), so ϕ is invertible and $\phi a \phi^{-1} = -a$: a and $-a$ would be conjugate, hence have the same eigenvalues. But the characteristic polynomial of a is $X^2 - 2X + 2$, with roots $1 \pm i$ in $\mathbb{F}_9$, while that of $-a$ is $X^2 + 2X + 2$, with roots $-1 \pm i$. For C_s and B: ϕ must anticommute with $\sigma = \mathrm{diag}(1, -1)$ (of determinant -1), so $\phi = \left(\begin{smallmatrix} 0 & x \\ y & 0 \end{smallmatrix}\right)$, and the other generator $\mathrm{diag}(-1, 1)$ of C_s imposes nothing new; in B, commuting with u forces $y = 0$. Finally $\rho \simeq \rho \otimes \det$ iff Hom contains an invertible element. Every entry was also checked by enumerating $\mathrm{GL}_2(\mathbb{F}_3)$, for instance with the following PARI/GP script, which prints, for each group, its order, $\dim \mathrm{End}_H$, $\dim(\mathrm{ad}^0\,\rho)^H$, $\dim \mathrm{Hom}$ and the dimension of its trace-zero part. □

Proposition 4.63 ($N_s(\mathbb{F}_3)$: induced over $\mathbb{F}_9$, not over $\mathbb{F}_3$)**.** *Let ρ be the standard representation of $N_s(\mathbb{F}_3) = \langle J, \sigma\rangle$ and $C_4 = \langle J\rangle = N_s(\mathbb{F}_3) \cap \mathrm{SL}_2(\mathbb{F}_3)$, the kernel of* det.

(i) ρ is absolutely irreducible, but $\mathrm{Res}_{C_4}\rho \otimes \mathbb{F}_9 \simeq \psi \oplus \psi^{-1}$ with $\psi(J) = i$, the eigenvectors being $v = (1, i)^t$ and $\sigma v = (1, -i)^t$. Since $\sigma J \sigma^{-1} = J^{-1}$, $\psi^\sigma = \psi^{-1} \neq \psi$.

(ii) In the basis $(v, \sigma v)$ of $\mathbb{F}_9^2$, $\rho(J) = \mathrm{diag}(i, -i)$ and $\rho(\sigma) = w$. This is the matrix form of $\mathrm{Ind}_{C_4}^{N_s}\psi$ of Proposition 4.39(iii) (with $s = \sigma$, $\sigma^2 = 1$), so $\rho \otimes \mathbb{F}_9 \simeq \mathrm{Ind}_{C_4}^{N_s}\psi$. Over $\mathbb{F}_3$, ρ is not induced from a character of C_4: $\mathrm{Res}_{C_4}\rho$ is irreducible over $\mathbb{F}_3$.

(iii) $\rho \simeq \rho \otimes \det$ over $\mathbb{F}_3$, with intertwiner J: $J\rho(g) = \det(g)\rho(g)J$ for all g. Moreover $\mathrm{tr}\, J = 0$, $J^2 = -1$, and the eigenlines of J over $\mathbb{F}_9$ are the two summands of (i), as Theorem 4.44(B) predicts.

(iv) The projective image is V_4, and $\rho \simeq \rho \otimes \chi$ for each of the three nontrivial characters χ of $N_s(\mathbb{F}_3)/\{\pm 1\}$: their kernels are C_4 ($\chi = \det$, intertwiner J), $C_s(\mathbb{F}_3) = \{\pm 1, \pm\sigma\}$ (intertwiner σ) and $\{\pm 1, \pm w\}$ (intertwiner w). So $\rho \otimes \mathbb{F}_9$ is induced from each of these three subgroups.

(v) $(\mathrm{ad}^0\rho \otimes \det)^{N_s} = \mathbb{F}_3 J$, a line, and $(\mathrm{ad}^0\rho)^{N_s} = 0$.

Proof. (i) Absolute irreducibility is Proposition 4.26(iv), and the decomposition over $\mathbb{F}_9$ is Example 4.14; $\sigma v = (1, -i)^t$ is the $(-i)$-eigenvector. $\sigma J \sigma^{-1} = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right) = J^{-1}$, so $\psi^\sigma(J) = \psi(J^{-1}) = -i$. (ii) $Jv = iv$ and $J(\sigma v) = -i\,\sigma v$; $\sigma(v) = \sigma v$ and $\sigma(\sigma v) = v$. The matrix of Proposition 4.39(iii) for ψ and $s = \sigma$ is $J \mapsto \mathrm{diag}(\psi(J), \psi^\sigma(J)) = \mathrm{diag}(i, -i)$ and $\sigma \mapsto \left(\begin{smallmatrix} 0 & \psi(1) \\ 1 & 0 \end{smallmatrix}\right) = w$. Over $\mathbb{F}_3$, $\mathrm{Res}_{C_4}\rho$ is irreducible (Example 4.14), whereas the restriction of a representation induced from a character of C_4 would contain that character as a line. (iii) It suffices to check the generators: $\det J = 1$ and J commutes with J; $\det\sigma = -1$ and $J\sigma = \left(\begin{smallmatrix} 0 & -1 \\ -1 & 0 \end{smallmatrix}\right) = -\sigma J$. And $\mathrm{tr}\, J = 0$, $J^2 = -1$, with eigenlines $\mathbb{F}_9 v$, $\mathbb{F}_9 \sigma v$. (iv) $N_s(\mathbb{F}_3)/\{\pm 1\}$ has order 4 and its three involutions $\bar{J}, \bar{\sigma}, \bar{w}$ commute, so it is V_4. The relations $wJ = -Jw$, $\sigma J = -J\sigma$, $w\sigma = -\sigma w$ show that $x \in \{J, \sigma, w\}$ commutes with ± 1 and $\pm x$ and anticommutes with the other four elements, so $x\rho(g) = \chi(g)\rho(g)x$ for the character χ with kernel $\{\pm 1, \pm x\}$. Induction from each kernel is Theorem 4.44 (or Proposition 4.46(iii)). (v) is Proposition 4.54(iii), (iv) with $\chi = \det \neq 1$ and (iii). □

Proposition 4.64 ($N_{ns}(\mathbb{F}_3)$)**.** *Let ρ be the standard representation of $N_{ns}(\mathbb{F}_3) = \langle a, \sigma\rangle$, with $Q_8 = N_{ns}(\mathbb{F}_3) \cap \mathrm{SL}_2(\mathbb{F}_3)$ the kernel of* det.

(i) ρ and $\mathrm{Res}_{Q_8}\rho$ are absolutely irreducible.

(ii) $\rho \not\simeq \rho \otimes \det$, and $(\mathrm{ad}^0\rho \otimes \det)^{N_{ns}} = 0$.

(iii) Over $\mathbb{F}_9$, $C_{ns}(\mathbb{F}_3) = \langle a \rangle$ acts on the lines spanned by $(1,-i)^t$ and $(1,i)^t$ by the characters θ and θ^3, where $\theta(a) = 1+i$ has order 8; $\theta^\sigma = \theta^3 \neq \theta$, and $\rho \otimes \mathbb{F}_9 \simeq \operatorname{Ind}_{C_{ns}}^{N_{ns}} \theta$. The projective image is D_4, and $\rho \simeq \rho \otimes \chi$ for exactly one nontrivial character χ, the character χ_{ns} with kernel $C_{ns}(\mathbb{F}_3)$, with intertwiner J.

Proof. (i) is Proposition 4.26(iv). (ii) If ϕ were an isomorphism, $\phi\rho(g)\phi^{-1} = \det(g)\rho(g)$ would give $\operatorname{tr}\rho(g) = \det(g)\operatorname{tr}\rho(g)$, so $\operatorname{tr}\rho(g) = 0$ whenever $\det g = -1$ (as $2 \neq 0$). But $\det a = 2 = -1$ and $\operatorname{tr} a = 2 \neq 0$. The invariants vanish by Proposition 4.54(iv). (iii) $a\binom{1}{-i} = \binom{1+i}{1-i} = (1+i)\binom{1}{-i}$, since $(1+i)(-i) = 1-i$; and $a\binom{1}{i} = (1-i)\binom{1}{i}$, with $1-i = (1+i)^3$. The element $1+i$ has order 8 in $\mathbb{F}_9^\times$ ($(1+i)^2 = 2i = -i$). From $\sigma a \sigma^{-1} = a^3$ (Chapter 1), $\theta^\sigma(a) = \theta(a^3) = \theta(a)^3$, and $\theta^3 \neq \theta$. So $\operatorname{Res}_{C_{ns}} \rho \otimes \mathbb{F}_9 \simeq \theta \oplus \theta^3$ is reducible, case (B) of Theorem 4.44 for $H = C_{ns}$, and $\rho \otimes \mathbb{F}_9 \simeq \operatorname{Ind}\theta$, $\rho \simeq \rho \otimes \chi_{ns}$. Directly, $J = a^2$ commutes with a and anticommutes with σ, so it is an intertwiner $\rho \to \rho \otimes \chi_{ns}$. The projective image $N_{ns}(\mathbb{F}_3)/\{\pm 1\}$ is D_4 (Proposition 4.62), of order 8, so by Proposition 4.46(iii) there is exactly one such character. □

Proposition 4.65 ($\mathrm{SL}_2(\mathbb{F}_3)$ and $\mathrm{GL}_2(\mathbb{F}_3)$)**.** *The standard representations of $\mathrm{SL}_2(\mathbb{F}_3)$ and $\mathrm{GL}_2(\mathbb{F}_3)$ are absolutely irreducible. For $\mathrm{GL}_2(\mathbb{F}_3)$, $\rho \not\simeq \rho \otimes \det$ and $(\mathrm{ad}^0\rho \otimes \det)^{\mathrm{GL}_2(\mathbb{F}_3)} = 0$. The projective images are A_4 and S_4, exceptional in Dickson's list (Theorem 4.84), so neither representation is induced from a subgroup of index 2.*

Proof. Absolute irreducibility: both contain Q_8 (Proposition 4.26(iii), (iv)). For $\mathrm{GL}_2(\mathbb{F}_3)$ argue as in Proposition 4.64(ii) with $a \in \mathrm{GL}_2(\mathbb{F}_3)$ (or with $\left(\begin{smallmatrix}0&1\\1&1\end{smallmatrix}\right)$, of determinant -1 and trace 1). Neither A_4 nor S_4 is dihedral, so Proposition 4.46(ii) applies. □

Theorem 4.66 (The three images)**.** *Let $H \leq \mathrm{GL}_2(\mathbb{F}_3)$ be conjugate to $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ or $N_s(\mathbb{F}_3)$ (by Chapter 1 these are exactly the subgroups with surjective determinant, no stable line in $\mathbb{F}_3^2$, and an element of determinant -1 and trace 0). Let $H_1 = H \cap \mathrm{SL}_2(\mathbb{F}_3)$, the kernel of $\det|_H$, of index 2, and ρ the standard representation. The following are equivalent:*

(a) H is conjugate to $N_s(\mathbb{F}_3)$;

(b) $\operatorname{Res}_{H_1}\rho$ is not absolutely irreducible;

(c) $\rho \simeq \rho \otimes \det$;

(d) $(\mathrm{ad}^0\rho \otimes \det)^H \neq 0$;

(e) $\rho \otimes \mathbb{F}_9 \simeq \operatorname{Ind}_{H_1}^H \psi$ for a character ψ of H_1 of order 4;

(f) H_1 is abelian.

When they hold, $(\mathrm{ad}^0\rho \otimes \det)^H$ is the line spanned by a trace-zero isomorphism $\rho \to \rho \otimes \det$; when they fail, $(\mathrm{ad}^0\rho \otimes \det)^H = 0$.

Proof. All statements are invariant under conjugation, so let H be one of the three models; then H_1 is $\mathrm{SL}_2(\mathbb{F}_3)$, Q_8 or C_4 (Chapter 1). (a)⇔(f): of these three only C_4 is abelian. (a)⇔(b): $\mathrm{SL}_2(\mathbb{F}_3)$ and Q_8 act absolutely irreducibly and C_4 does not (Proposition 4.26(iv)). (b)⇔(c): Theorem 4.44 with $\chi_H = \det|_H$ (its kernel is H_1, of index 2 because det is onto $\{\pm 1\}$), $\operatorname{char}\mathbb{F}_3 \neq 2$ and ρ absolutely irreducible. (c)⇔(d) and the description of the invariants: Proposition 4.54(iii), (iv). (a)⇒(e): Proposition 4.63(ii), $\psi(J) = i$ of order 4. (e)⇒(b): $\operatorname{Res}_{H_1}\operatorname{Ind}_{H_1}^H \psi \simeq \psi \oplus \psi^s$ is reducible over $\mathbb{F}_9$. □

In the paper 4.67. Proposition prop:ns and its proof. As $\det \bar\rho_{E,3} = \bar\chi_3 = \chi_{-3}$ cuts out $\mathbb{Q}(\sqrt{-3})$ (Chapter 5), the image of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$ is H_1, and Theorem 4.66 gives at once: $\bar\rho_{E,3}$ is absolutely irreducible on $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$ unless the image is $N_s(\mathbb{F}_3)$; in that case $\bar\rho \otimes \mathbb{F}_9$ is induced from a character of order 4, $\bar\rho \simeq \bar\rho \otimes \chi_{-3}$ and $H^0(\mathbb{Q}, \mathrm{ad}^0\,\bar\rho(1)) \neq 0$. The value $h_3(E) = 1$ then comes from Lemma lem:h0 (Proposition 4.81). This is also the reading of the hypothesis of Theorem thm:main at $\ell = 3$ (Proposition prop:Sf), and of Remark rem:ns and Section sec:anomaly, which concern exactly the image 3Ns. That $N_s(\mathbb{F}_3)$ is the only one of the three images whose determinant-one subgroup is abelian is the orbit dichotomy of Chapter 1 in another form.

4.9 Unipotent elements and cyclic groups of order 2, 3, 4, 6

This section computes the fixed vectors of the groups that occur as images of inertia at a bad prime $q \neq \ell$: unipotent groups and "minus unipotent" ones (potentially multiplicative reduction), and cyclic groups of order 2, 3, 4, 6 in SL_2 (potentially good reduction), on V, on $\mathrm{ad}^0 V$, and modulo 3. In the paper these computations are Lemma lem:IV, Remark rem:types, Lemma lem:euler, the table of Section 1 and Proposition prop:ns-structure. Which shape occurs for which Kodaira type is a theorem about elliptic curves (Serre-Tate, Kraus) proved in Chapter 10 and Chapter 11; here it is only recorded in the table of Proposition 4.71.

Convention 4.68. In this section σ denotes an element of order 3 of SL_2, as in the paper's Lemmas lem:IV and lem:euler, and τ an element of order 4; the matrix $\mathrm{diag}(1,-1)$, called σ in Chapter 1 and in Section 4.8, is written h here (it is the basis vector h of $\mathrm{ad}^0 V$ viewed as a matrix). A Frobenius element is an abstract F satisfying $FgF^{-1} = g^q$ on the inertia image (convention (C8)).

Proposition 4.69 (Unipotent elements)**.** *Let k be a field, $V = k^2$, $u \in \mathrm{GL}_2(k)$ unipotent (characteristic polynomial $(X-1)^2$) with $u \neq 1$, $\nu = u - 1$, and $\xi \in k^\times$, $\xi \neq 1$.*

(i) $\nu \neq 0$ and $\nu^2 = 0$; in a basis $e_1 \in \ker\nu$, $e_2 \notin \ker\nu$ one has $u = \left(\begin{smallmatrix} 1 & n' \\ 0 & 1 \end{smallmatrix}\right)$ with $n' \neq 0$. $V^u = \ker\nu = \mathrm{im}\,\nu$ is a line, and $V^{\xi u} = 0$. In particular "minus a unipotent" ($\xi = -1$, $\mathrm{char}\,k \neq 2$) fixes no nonzero vector.

(ii) If $\mathrm{char}\,k \neq 2$, then $(\mathrm{ad}^0 V)^u = (\mathrm{ad}^0 V)^{\xi u} = k\nu = k\,e$, a line. If $\mathrm{char}\,k = 2$, $(\mathrm{ad}^0 V)^u = ke + kh$. The same holds for any group H acting through matrices $\xi' u^m$ (ξ' scalar, $m \in \mathbb{Z}$) one of which has $u^m \neq 1$.

(iii) If $F \in \mathrm{GL}_2(k)$ satisfies $FuF^{-1} = u^q$ with $q \in \mathbb{Z}$, then F preserves $(\mathrm{ad}^0 V)^u$ and acts on it by q: $F\nu F^{-1} = u^q - 1 = q\nu$. Hence F^{-1} acts by q^{-1} when $q \in k^\times$. The same holds for $q \in \mathbb{Z}_\ell$ when $k \supseteq \mathbb{Q}_\ell$ and u^q is defined by continuity, $u^q = 1 + q\nu$.

Proof. (i) By Cayley-Hamilton $\nu^2 = 0$, and $\nu \neq 0$ as $u \neq 1$. Then $\mathrm{im}\,\nu \subseteq \ker\nu$, both are lines, so they are equal. For $e_2 \notin \ker\nu$, $\nu e_2 \in \ker\nu \setminus \{0\}$, say $\nu e_2 = n' e_1$. A vector fixed by ξu would be an eigenvector of u with eigenvalue $\xi^{-1} \neq 1$, but 1 is the only eigenvalue of u. (ii) Scalars act trivially on $\mathrm{ad}^0 V$, so $(\mathrm{ad}^0 V)^{\xi u} = (\mathrm{ad}^0 V)^u$. By Proposition 4.52(iii) with $t = u$, for $x = \alpha e + \beta h + \gamma f$, $(u-1)x = (-2n'\beta - n'^2\gamma)e + n'\gamma h$, which vanishes iff $\gamma = 0$ and $2\beta = 0$. For H: $u^m = 1 + m\nu$, and if $u^m \neq 1$ it is again a nontrivial unipotent with $(\mathrm{ad}^0 V)^{u^m} = ke$; every element of H fixes e. (iii) $F\nu F^{-1} = FuF^{-1} - 1 = u^q - 1$, and $u^q = (1+\nu)^q = 1 + q\nu$ for every $q \in \mathbb{Z}$ (binomial theorem with $\nu^2 = 0$, and $(1+\nu)^{-1} = 1 - \nu$). By continuity the same holds for $q \in \mathbb{Z}_\ell$. □

Lemma 4.70 (The commutant of one matrix)**.** *Let $x \in \mathrm{End}_k(V)$, $n = \dim V$.*

(i) If the characteristic polynomial of x has n distinct roots in $\bar{k}$, the commutant $\{y : xy = yx\}$ is $k[x] \simeq k[X]/(\det(X - x))$, of dimension n.

(ii) If $n = 2$ and x is not a scalar, the commutant is $k \cdot 1 \oplus k \cdot x = k[x]$; if moreover $\mathrm{char}\, k \neq 2$, its trace-zero part is the line spanned by $2x - \mathrm{tr}\, x$.

(iii) In (i) and (ii) the commutant is a field iff $\det(X - x)$ is irreducible over k.

Examples: if $\sigma^2+\sigma+1 = 0$ (σ of order 3 in SL_2), the trace-zero line is spanned by $2\sigma+1 = \sigma-\sigma^{-1}$, and $(2\sigma+1)^2 = -3$; if $\tau^2 = -1$, it is $k\tau$. For $k = \mathbb{Q}_\ell$ and σ of order 3 in $\mathrm{SL}_2(\mathbb{Q}_\ell)$ the commutant $\mathbb{Q}_\ell[\sigma] \simeq \mathbb{Q}_\ell[X]/(X^2 + X + 1)$ is a field iff $\ell \not\equiv 1 \pmod 3$, and for τ of order 4, $\mathbb{Q}_\ell[\tau]$ is a field iff $\ell \not\equiv 1 \pmod 4$ (the roots of unity of $\mathbb{Q}_\ell$, Chapter 7).

Proof. (i) The minimal polynomial of x vanishes at all n eigenvalues, so it has degree n and equals $\det(X - x)$; hence $k[x] \simeq k[X]/(\det(X - x))$ has dimension n, and $k[x]$ lies in the commutant. Over $\bar{k}$, x is diagonal with distinct entries in a suitable basis, and the matrices commuting with it are the diagonal ones, of dimension n. The commutant is the solution space of a linear system with coefficients in k, so its dimension over k is also n (as in Proposition 4.7(i)); it therefore equals $k[x]$. (ii) Choose v that is not an eigenvector of x (the eigenvectors lie in at most two lines, or in one line if x has a single eigenvalue and is not scalar), while k^2 contains at least the three lines spanned by $(1,0)^t$, $(0,1)^t$, $(1,1)^t$, so such a v exists over every field. Then v, xv is a basis (if xv were a multiple of v, v would be an eigenvector). If y commutes with x, write $yv = \alpha v + \beta xv$; then y and $\alpha + \beta x$ agree on v and on xv ($y\,xv = x\,yv = (\alpha + \beta x)xv$), so $y = \alpha + \beta x$. The trace of $\alpha + \beta x$ is $2\alpha + \beta\,\mathrm{tr}\, x$, which vanishes iff $\alpha + \beta x = \frac{\beta}{2}(2x - \mathrm{tr}\, x)$. (iii) $k[X]/(P)$ is a field iff P is irreducible. For the examples: $\mathrm{tr}\,\sigma = -1$, so $2\sigma - \mathrm{tr}\,\sigma = 2\sigma + 1$, $\sigma^{-1} = \sigma^2 = -1 - \sigma$, and $(2\sigma + 1)^2 = 4(\sigma^2 + \sigma) + 1 = -3$; $\mathrm{tr}\,\tau = 0$. □

Proposition 4.71 (Cyclic groups of order $2, 3, 4, 6$)**.** *Let K be a field, $V = K^2$, and $g \in \mathrm{SL}_2(K)$ of finite order $m \in \{2, 3, 4, 6\}$ with $\mathrm{char}\, K \nmid m$.*

(i) If $m = 2$ then $g = -1$. If $m \geq 3$, g has the distinct eigenvalues ζ, ζ^{-1} with ζ a primitive m-th root of unity, and characteristic polynomial Φ_m: $X^2 + X + 1$, $X^2 + 1$, $X^2 - X + 1$ for $m = 3, 4, 6$. For $m = 6$, $\sigma = -g$ has order 3.

(ii) $V^g = 0$. If $m = 2$, $(\mathrm{ad}^0 V)^g = \mathrm{ad}^0 V$. If $m \geq 3$, $(\mathrm{ad}^0 V)^g$ is the line spanned by $g - g^{-1}$, which is $2g + 1$ for $m = 3$, $2g$ for $m = 4$, and $2g - 1 = -(2\sigma + 1)$ for $m = 6$.

(iii) Let $F \in \mathrm{GL}_2(K)$ with $FgF^{-1} = g^r$, $r \in \mathbb{Z}$ prime to m. If $m \geq 3$, then F preserves $(\mathrm{ad}^0 V)^g$ and acts on it by $+1$ if $r \equiv 1 \pmod m$ and by -1 if $r \equiv -1 \pmod m$, and every r prime to m is $\equiv \pm 1 \pmod m$. For $r = q$ a prime not dividing m the sign is $\chi_{-3}(q)$ if $m \in \{3, 6\}$ and $\chi_{-4}(q)$ if $m = 4$; it is the same for F^{-1}.

Proof. (i) $X^m - 1$ is separable since $\mathrm{char}\, K \nmid m$, so g is diagonalisable over $\bar{K}$ with eigenvalues m-th roots of unity of product $\det g = 1$. If the two eigenvalues are equal, to ζ say, then $\zeta^2 = 1$ and $g = \zeta = \pm 1$, of order at most 2; this is the case $m = 2$, $g = -1$. Otherwise they are $\zeta \neq \zeta^{-1}$, the order of g is that of ζ, so ζ is a primitive m-th root, and $(X - \zeta)(X - \zeta^{-1}) = \Phi_m$ because Φ_m has degree 2 for these m. For $m = 6$, g^3 has the eigenvalues $\zeta^{\pm 3} = -1$, so $g^3 = -1$ and $(-g)^3 = 1$, with $-g \neq 1$. (ii) 1 is not an eigenvalue. Conjugation by -1 is trivial. For $m \geq 3$,

Lemma 4.70(ii) gives the line $K(2g - \operatorname{tr} g)$; and $g - g^{-1}$ has trace 0 and lies in $K[g]$, and is nonzero since $g^2 \neq 1$. The three expressions follow from $g^{-1} = -1 - g$, $-g$, $1 - g$ respectively. (iii) F normalises $\langle g \rangle$, so it preserves the invariants, and $F(g - g^{-1})F^{-1} = g^r - g^{-r}$. The units modulo 3, 4, 6 are ± 1, and $g^{\pm 1} - g^{\mp 1} = \pm(g - g^{-1})$. Finally $q \equiv \chi_{-3}(q) \pmod 3$ for a prime $q \neq 3$ (including $q = 2$, where both sides are -1 modulo 3) and $q \equiv \chi_{-4}(q) \pmod 4$ for an odd prime q (Chapter 2); and for $m = 6$ a prime $q \geq 5$ is $\equiv \pm 1 \pmod 6$ with the sign of q mod 3. F^{-1} acts by the inverse sign, which is the same. □

The following table collects the fixed spaces for the shapes of the image of inertia $I = I_q$ at a prime $q \neq \ell$, $q \geq 5$, on $V = V_\ell E$ (dimension 2 over $\mathbb{Q}_\ell$). The first column is Chapter 10 and Chapter 11's (Serre-Tate, Kraus), the other columns are Proposition 4.69, Proposition 4.71 and Proposition 4.72. In the unipotent rows the image of I is infinite, topologically generated, up to the finite part, by $t = \left(\begin{smallmatrix} 1 & n' \\ 0 & 1 \end{smallmatrix}\right)$; ξ is a ramified quadratic character. The column "F" gives the action of an arithmetic Frobenius F ($FgF^{-1} = g^q$) on $(\mathrm{ad}^0 V)^I$; the geometric Frobenius F^{-1} gives the inverse, which matters only in the unipotent rows (q against q^{-1}; convention B-C3(d)). The last column is $\dim(T/3T)^I$ for $T = T_3 E$.

image of I	types	$\dim V^I$	$\dim(\mathrm{ad}^0 V)^I$	generator	F on $(\mathrm{ad}^0 V)^I$	$\dim(T/3T)^I$
trivial	I_0	2	3	$\mathrm{ad}^0 V$	$\alpha/\beta, 1, \beta/\alpha$	2
$\{\pm 1\}$	I_0^*	0	3	$\mathrm{ad}^0 V$	as for the twist	0
unipotent, $t \neq 1$	I_n	1	1	e	q	1 or 2
ξ·unipotent	I_n^*	0	1	e	q	0
order 3	IV, IV*	0	1	$2\sigma + 1$	$\chi_{-3}(q)$	1
order 4	III, III*	0	1	τ	$\chi_{-4}(q)$	0
order 6, $-\sigma$	II, II*	0	1	$2\sigma + 1$	$\chi_{-3}(q)$	0

In the row I_n, $\dim(T/3T)^I$ is 1 if $3 \nmid n'$ and 2 if $3 \mid n'$; for the Tate curve $v_3(n') = v_3(n)$ (Chapter 10). In the row I_0^* the eigenvalues of F on $\mathrm{ad}^0 V$ are those of the unramified twist V' (Proposition 4.48(iii)). The degree of $L_q(A_f, s)^{-1}$ is $\dim(\mathrm{ad}^0 V)^I$, that is, $3, 3, 1, 1, 1, 1, 1$, and $\delta_q = \dim V^I$ is $2, 0, 1, 0, 0, 0, 0$ (Definition def:terms). The row I_n holds at every $q \neq \ell$, the rows I_0^*, I_n^* at every odd $q \neq \ell$; for the finite images the tame relation $FgF^{-1} = g^q$ needs the image to be tame, which holds for $q \geq 5$ (Chapter 7).

Proposition 4.72 (Reduction of finite cyclic subgroups of $\mathrm{SL}_2(\mathbb{Z}_\ell)$)**.** *Let ℓ be a prime, $T = \mathbb{Z}_\ell^2$, $g \in \mathrm{SL}_2(\mathbb{Z}_\ell)$ of finite order $m \in \{2, 3, 4, 6\}$, and $\bar{g}$ its reduction modulo ℓ.*

(i) If $\ell \nmid m$, then $\bar{g}$ has order m, and the invariants of $\langle g \rangle$ on T and on $\mathrm{ad}^0 T$ commute with reduction: $(T/\ell^j T)^g = T^g/\ell^j T^g$ and $(\mathrm{ad}^0 T/\ell^j)^g = (\mathrm{ad}^0 T)^g/\ell^j$. In particular $(T/\ell T)^g = 0$.

(ii) Let $\ell = 3$, $m = 3$. Then $\bar{g}$ is a nontrivial unipotent element of $\mathrm{SL}_2(\mathbb{F}_3)$, so $(T/3T)^g$ is a line while $T^g = 0$: invariants do not commute with reduction. On the adjoint they do: $(\mathrm{ad}^0 T)^g = \mathbb{Z}_3(2g + 1)$ and $2g + 1 \not\equiv 0 \pmod 3$ spans $(\mathrm{ad}^0 T/3)^g$.

(iii) Let $\ell = 3$, $m = 6$. Then $\bar{g} = -\bar{u}$ with $\bar{u}$ a nontrivial unipotent, and $(T/3T)^g = 0$.

(iv) Let $\ell = 3$, $m \in \{2, 4\}$. Then $(T/3T)^g = 0$; for $m = 4$, $\bar{g}$ has the irreducible characteristic polynomial $X^2 + 1$ over $\mathbb{F}_3$ and eigenvalues $\pm i \in \mathbb{F}_9$.

(v) Let ℓ be odd and $m \geq 3$. Then $\bar{g}$ is not a scalar, and the commutant of g in $\mathrm{End}_{\mathbb{Z}_\ell}(T)$ is $\mathbb{Z}_\ell[g] = \mathbb{Z}_\ell \oplus \mathbb{Z}_\ell g \simeq \mathbb{Z}_\ell[X]/(\Phi_m)$. Moreover T is free of rank one over $\mathbb{Z}_\ell[g]$; for $\ell = 3$, $m = 3$, this gives $T/3T \simeq \mathbb{Z}_3[\zeta_3]/(\pi^2)$, $\pi = 1 - \zeta_3$, with $(T/3T)^g = \pi T/3T$.

Proof. First, the kernel $1+\ell\mathrm{M}_2(\mathbb{Z}_\ell)$ of reduction contains no element $\gamma \neq 1$ of finite order prime to ℓ, and for ℓ odd no element of order ℓ. Write $\gamma = 1+\ell^a y$ with $a \geq 1$ and $y \not\equiv 0 \pmod{\ell}$. For r prime to ℓ, $\gamma^r \equiv 1 + r\ell^a y \pmod{\ell^{a+1}}$, so $\gamma^r \neq 1$. For ℓ odd, $\gamma^\ell = 1 + \ell^{a+1}y + \binom{\ell}{2}\ell^{2a}y^2 + \cdots \equiv 1 + \ell^{a+1}y \pmod{\ell^{a+2}}$, because $\ell \mid \binom{\ell}{j}$ for $0 < j < \ell$, $2a+1 \geq a+2$ and $\ell a \geq a+2$ (using $\ell \geq 3$); so $\gamma^\ell \neq 1$ (this is also in Chapter 1). A nontrivial finite group contains an element of prime order, so the finite subgroups of the kernel are trivial when ℓ is odd, and the finite subgroups of order prime to ℓ are trivial for every ℓ. Hence reduction modulo ℓ is injective on $\langle g\rangle$ if ℓ is odd or $\ell \nmid m$. (i) $\bar{g}$ has order m by the above, and $\#\langle g\rangle = m \in \mathbb{Z}_\ell^\times$; apply Theorem 4.18(ii) to the lattices T and $\mathrm{ad}^0 T$. $T^g = 0$ by Proposition 4.71(ii). (ii) $\bar{g} \neq 1$ by injectivity, and its characteristic polynomial is $X^2 + X + 1 \equiv (X-1)^2 \pmod 3$; so $\bar{g}$ is a nontrivial unipotent and $(T/3T)^g$ is a line (Proposition 4.69(i)), while $T^g = 0$. On the adjoint, $(\mathrm{ad}^0 T)^g = \mathrm{ad}^0 T \cap \mathbb{Q}_3(2g+1)$ by Proposition 4.71(ii). If $2g+1 \equiv 0 \pmod 3$ then $g \equiv -2^{-1}\cdot 1 = 1 \pmod 3$, which is false; so $2g+1$ is not divisible by 3 in $\mathrm{End}(T)$, and $\mathrm{ad}^0 T \cap \mathbb{Q}_3(2g+1) = \mathbb{Z}_3(2g+1)$. Its reduction $2\bar{g}+1 = -(\bar{g}-1)$ spans $(\mathrm{ad}^0 T/3)^g = \mathbb{F}_3(\bar{g}-1)$ (Proposition 4.69(ii)). (iii) $g = -\sigma$ with $\sigma = -g$ of order 3; by (ii) $\bar{\sigma}$ is a nontrivial unipotent, and $-\bar{\sigma}$ fixes no nonzero vector (Proposition 4.69(i)). (iv) is (i), as $3 \nmid m$; for $m = 4$ the characteristic polynomial is $\Phi_4 = X^2 + 1$, without roots in $\mathbb{F}_3$. (v) $\bar{g}$ is not a scalar: if $\ell \nmid m$, $\bar{g}$ has order $m \geq 3$ while a scalar of determinant 1 is ± 1; if $\ell = 3$, $\bar{g}$ is $\pm$ a nontrivial unipotent. So 1 and g are linearly independent modulo ℓ. Extend $\bar{1}, \bar{g}$ to a basis of $\mathrm{End}(T/\ell T)$ and lift it; by Nakayama's lemma the lift, which contains 1 and g, is a $\mathbb{Z}_\ell$-basis of the free module $\mathrm{End}_{\mathbb{Z}_\ell}(T) \simeq \mathbb{Z}_\ell^4$. Hence $\mathbb{Z}_\ell \oplus \mathbb{Z}_\ell g$ is a direct summand of $\mathrm{End}_{\mathbb{Z}_\ell}(T)$: an element $\alpha + \beta g$ with $\alpha, \beta \in \mathbb{Q}_\ell$ lies in $\mathrm{End}_{\mathbb{Z}_\ell}(T)$ iff $\alpha, \beta \in \mathbb{Z}_\ell$. So the commutant $\mathrm{End}_{\mathbb{Z}_\ell}(T) \cap (\mathbb{Q}_\ell \oplus \mathbb{Q}_\ell g)$ (Lemma 4.70(ii) over $\mathbb{Q}_\ell$) is $\mathbb{Z}_\ell \oplus \mathbb{Z}_\ell g$. The freeness of T over $\mathbb{Z}_\ell[g]$ and the description of $T/3T$ are proved in Chapter 6; we do not prove them here. (The fixed space $\pi T/3T$ is the kernel of $g-1$, which acts as multiplication by $\zeta_3 - 1 = -\pi$.) □

In the paper 4.73. Lemma lem:IV (types IV, IV* at $q \neq 3$): "its image in $\mathrm{Aut}(E[3])$ is a nontrivial unipotent subgroup. Consequently $E[3]^{I_q}$ is a line" is Proposition 4.72(ii), and "reduction modulo 3 is injective on it, the kernel of $\mathrm{GL}_2(\mathbb{Z}_3) \to \mathrm{GL}_2(\mathbb{F}_3)$ being torsion-free" is the first paragraph of its proof; the route through T_3E free of rank one over $\mathbb{Z}_3[X]/(X^2+X+1)$, in the unnumbered paragraph after the lemma in the paper, is (v). "the trace-zero endomorphisms commuting with σ form the line spanned by $\sigma - \sigma^{-1} = 2\sigma + 1$" is Lemma 4.70, and "$\mathrm{Frob}_q$, and therefore also Frob_q^{-1}, acts on the line by $\chi_{-3}(q)$" is Proposition 4.71(iii). In the exclusion of potentially multiplicative reduction, "$\bar{\rho}_{E,3}(I_q)$ would contain -1, which fixes no line" is trivial: the scalar -1 fixes no nonzero vector of $E[3]$, so $E[3]^{I_q}$ would be 0. Remark rem:types ("$E[3]^{I_q} = 0$" for I_0^*, III, III*, II, II*, I_n^*) is (iii), (iv) and Proposition 4.69(i). Lemma lem:euler is the table above: types II, IV and their duals use $2\sigma + 1$ inside $\mathrm{End}_{I_q}(T) = \mathbb{Z}_\ell[\sigma]$, which is not a field for $\ell \equiv 1 \pmod 3$ ((v) and Lemma 4.70); types III, III* use the line $\mathbb{Q}_\ell\tau$, with no need to diagonalise τ over $\mathbb{Q}_\ell$; type I_n uses Proposition 4.69(iii) with the geometric Frobenius, eigenvalue q^{-1}. Proposition prop:ns-structure (ii): "The trace-zero endomorphisms commuting with τ form the line spanned by τ" and "the sign can be read modulo 3" are Lemma 4.70 and the injectivity of reduction on $\langle\tau\rangle$ (order 4, prime to 3).

4.10 Representations over $\mathbb{Z}_\ell$: lattices, reduction, homothety

This section passes from representations over $\mathbb{Q}_\ell$ to representations over $\mathbb{Z}_\ell$ and modulo ℓ^m. In the paper $T = T_\ell E$ is a $G_{\mathbb{Q}}$-stable lattice in $V = V_\ell E$, $\bar{\rho}$ is its reduction, $\rho \bmod \ell^k$ its reduction

modulo ℓ^k, $A = \mathrm{ad}^0 T$ is a lattice in A_f, and the term $h_\ell(E)$ of Lemma lem:h0 is "the largest k such that $\rho \bmod \ell^k \simeq (\rho \otimes \chi_\ell) \bmod \ell^k$". Everything is proved for an abstract group and a discrete valuation ring $\mathcal{O}$ (convention (C7)).

Definition 4.74. Let V be a representation of G over $K = \mathrm{Frac}\,\mathcal{O}$. A *lattice* in V is a finitely generated $\mathcal{O}$-submodule L spanning V; it is *G-stable* if $\rho(g)L = L$ for all g. Then $\rho_L \colon G \to \mathrm{GL}(L) \simeq \mathrm{GL}_n(\mathcal{O})$, conjugate in $\mathrm{GL}_n(K)$ to ρ, and $\bar\rho_L$ is the representation of G on $L/\varpi L$ over the residue field; $\rho_L \bmod \varpi^m$ is the representation on $L/\varpi^m L$. Two lattices are *homothetic* if $L' = cL$ for some $c \in K^\times$, equivalently $L' = \varpi^m L$ for some $m \in \mathbb{Z}$.

Proposition 4.75 (Stable lattices)**.** *(i) For any two lattices L, L' there are $a, b \geq 0$ with $\varpi^a L \subseteq L' \subseteq \varpi^{-b} L$.*

(ii) If G is finite, or more generally if the stabiliser of a lattice L_0 has finite index in G, then $L = \sum_g \rho(g) L_0$ (a finite sum over coset representatives) is a G-stable lattice.

(iii) If L is stable, so are $\varpi^m L$, $L^\vee = \mathrm{Hom}_{\mathcal{O}}(L, \mathcal{O}) \subseteq V^\vee$, $L \otimes \mathcal{O}(\chi)$ for a character $\chi \colon G \to \mathcal{O}^\times$, $\mathrm{End}_{\mathcal{O}}(L) \subseteq \mathrm{End}_K(V)$, and $\mathrm{ad}^0 L = \mathrm{End}_{\mathcal{O}}(L) \cap \mathrm{ad}^0 V$. Moreover $\mathrm{End}_{\mathcal{O}}(L) = \mathrm{ad}^0 L \oplus \mathcal{O} E_{11}$ as $\mathcal{O}$-modules, so $\mathrm{ad}^0 L/\varpi^m \mathrm{ad}^0 L = \mathrm{ad}^0(L/\varpi^m L)$, the trace-zero endomorphisms of $L/\varpi^m L$.

Proof. (i) Each of the finitely many generators of L' is a K-combination of a basis of L, so lies in $\varpi^{-b} L$ for b large; exchange the roles for a. (ii) Let G_0 be the stabiliser of L_0 and $s_1, \dots, s_r$ representatives of the cosets gG_0. Then $\rho(g)L_0$ depends only on the coset gG_0, so $\sum_g \rho(g)L_0 = \sum_i \rho(s_i)L_0$ is a finite sum of lattices; it is finitely generated and spans V. For $h \in G$, $\rho(h)\sum_g \rho(g)L_0 = \sum_g \rho(hg)L_0$ is the same sum, so it is stable. This covers a continuous representation of a compact group G on V, K a finite extension of $\mathbb{Q}_\ell$: the stabiliser of L_0 is the preimage of the open subgroup $\mathrm{GL}(L_0)$ of $\mathrm{GL}(V)$, hence open, hence of finite index. (iii) $(g\lambda)(L) = \lambda(g^{-1}L) = \lambda(L) \subseteq \mathcal{O}$; $\chi(g)$ is a unit; $\rho(g)x\rho(g)^{-1}$ preserves L if x does; the trace is invariant. The trace $\mathrm{End}_{\mathcal{O}}(L) \to \mathcal{O}$ is onto ($\mathrm{tr}\, E_{11} = 1$) and split by $c \mapsto cE_{11}$, so its kernel $\mathrm{ad}^0 L$ is a direct summand, and the split exact sequence $0 \to \mathrm{ad}^0 L \to \mathrm{End}_{\mathcal{O}}(L) \to \mathcal{O} \to 0$ stays exact modulo ϖ^m, with $\mathrm{End}_{\mathcal{O}}(L)/\varpi^m = \mathrm{End}(L/\varpi^m L)$ since L is free. □

Proposition 4.76 (Reduction and semisimplification)**.** *Let L be a G-stable lattice in V.*

(i) $\det(X - \bar\rho_L(g))$ is the reduction of $\det(X - \rho(g)) \in \mathcal{O}[X]$; it does not depend on L.

(ii) Hence (Brauer-Nesbitt, Theorem 4.35) $\bar\rho_L^{ss}$ does not depend on L; it is written $\bar\rho^{ss}$.

(iii) If $\bar\rho_L$ is irreducible for one L, then $\bar\rho_{L'} \simeq \bar\rho_L$ for every stable lattice L'.

Proof. (i) The characteristic polynomial of $\rho_L(g) \in \mathrm{GL}_n(\mathcal{O})$ is that of the conjugate $\rho(g)$, with coefficients in $\mathcal{O}$, and reduction commutes with taking characteristic polynomials. (ii) is immediate. (iii) $\bar\rho_{L'}^{ss} \simeq \bar\rho_L$ is irreducible of full dimension, so $\bar\rho_{L'}$ has one composition factor and $\bar\rho_{L'} \simeq \bar\rho_L$ (Corollary 4.36(ii) with $k' = k$). □

Theorem 4.77 (The homothety lemma)**.** *If $\bar\rho_L$ is irreducible, every G-stable lattice $L' \subseteq V$ is homothetic to L: $L' = \varpi^m L$ for a unique $m \in \mathbb{Z}$.*

Proof. By Proposition 4.75(i) the set of $m \in \mathbb{Z}$ with $L' \subseteq \varpi^m L$ is nonempty and bounded above (as $L' \neq 0$ and $\bigcap_m \varpi^m L = 0$); let m be its maximum and replace L' by $\varpi^{-m} L'$. Then $L' \subseteq L$ and $L' \not\subseteq \varpi L$, so the image of L' in $L/\varpi L$ is a nonzero G-stable subspace, hence all of $L/\varpi L$ since $\bar{\rho}_L$ is irreducible. Thus $L' + \varpi L = L$, and $L' = L$ by Nakayama's lemma (Chapter 3). Uniqueness: $\varpi^m L = L$ with $m \neq 0$ would give $L = \varpi L$, hence $L = 0$ by Nakayama. □

In the paper 4.78. Section 4.2. Proposition prop:pullback identifies the lattice $M_{f,\lambda}$ of DFG04 with $H^1(E, \mathbb{Z}_\ell)$ itself, so the paper does not need the homothety lemma there. It gives a second route when $\bar{\rho}$ is irreducible: as $M_{f,\lambda} \subseteq H^1$ is a lattice in the dual $V_\ell E^\vee$, Theorem 4.77 applies to $M_{f,\lambda}$ and $T_\ell E^\vee$ inside $V_\ell E^\vee$ (both stable, and $T_\ell E^\vee/\ell \simeq \bar{\rho}^\vee$ is irreducible), after which Proposition 4.60(iv) identifies $\mathrm{ad}^0 M_{f,\lambda}$ with $\mathrm{ad}^0 T$. The homothety lemma is also the reason why, when $E[\ell]$ is irreducible, every curve in the isogeny class has the same T_ℓ up to homothety, hence the same $\mathrm{ad}^0 T$ (Section 1, "at such an ℓ the choice of the optimal curve does not matter"; Chapter 9).

Example 4.79 (Non-homothetic lattices)**.** Let $G \subseteq \mathrm{GL}_2(\mathbb{Z}_\ell)$ consist of upper triangular matrices and contain $t = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. Then $L = \mathbb{Z}_\ell e_1 \oplus \mathbb{Z}_\ell e_2$ and $L' = \mathbb{Z}_\ell e_1 \oplus \ell\mathbb{Z}_\ell e_2$ are G-stable and not homothetic (L' has index ℓ in L, while $\varpi^m L$ has index ℓ^{2m}). In the basis $e_1, \ell e_2$ of L' the matrix of $g = \left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)$ is $\left(\begin{smallmatrix} a & \ell b \\ 0 & d \end{smallmatrix}\right)$, so $\bar{\rho}_{L'}$ is the direct sum of the two characters $g \mapsto \bar{a}$, $g \mapsto \bar{d}$, while $\bar{\rho}_L$ is the non-split extension of the same two characters (Proposition 4.24: $\bar{t}$ is a nontrivial unipotent, so $\mathbb{F}_\ell e_1$ is the only stable line). Same semisimplification (Proposition 4.76), non-isomorphic reductions. For elliptic curves, the Tate modules of two ℓ-isogenous curves give such a pair (Chapter 9, Chapter 11); this is why the Eisenstein case of the paper (Section sec:eis, Conjecture conj:eis) behaves differently.

Theorem 4.80 (Ribet's lemma)**.** *Let K be a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}$, G a compact group and $\rho\colon G \to \mathrm{GL}_2(K)$ a continuous irreducible representation such that $\bar{\rho}^{ss} \simeq \eta_1 \oplus \eta_2$ for characters η_1, η_2. Then there is a G-stable lattice L whose reduction $\bar{\rho}_L$ is a non-split extension with sub-character η_1 (and one with sub-character η_2).*

Proof. We do not prove this; see [157, Section 2]. (The idea: among the stable lattices, which up to homothety form a bounded convex subset (a finite subtree) of the tree of $\mathrm{PGL}_2(K)$ because ρ is irreducible, an extremal one has a reduction with the required non-split shape.) In the literature "Ribet's lemma" usually means this statement; the name is sometimes also attached to Theorem 4.77, which concerns the opposite situation of an irreducible reduction. □

Proposition 4.81 (Twisted self-isomorphisms modulo ϖ^m)**.** *Let G be any group, T free of rank n over $\mathcal{O}$ with a G-action such that $\bar{T} = T/\varpi T$ is absolutely irreducible, and $\chi\colon G \to \mathcal{O}^\times$ a character, with reduction $\bar{\chi}$. For $m \geq 1$ put $M_m = \mathrm{Hom}_G(T/\varpi^m, (T/\varpi^m)(\chi))$.*

(i) For $\phi \in \mathrm{End}(T/\varpi^m)$, $\varpi^{m-1}\phi \neq 0$ iff $\phi(T/\varpi^m) \not\subseteq \varpi(T/\varpi^m)$. The ϖ-torsion of M_m is isomorphic to $\mathrm{Hom}_G(\bar{T}, \bar{T}(\bar{\chi}))$, of dimension at most 1, so $M_m \simeq \mathcal{O}/\varpi^j$ for some $j \leq m$.

(ii) An element $\phi \in M_m$ with $\varpi^{m-1}\phi \neq 0$ is an isomorphism $T/\varpi^m \simeq (T/\varpi^m)(\chi)$. Conversely an isomorphism has $\varpi^{m-1}\phi \neq 0$, so it generates $M_m \simeq \mathcal{O}/\varpi^m$.

(iii) Let $h = \sup\{m \geq 0 : T/\varpi^m \simeq (T/\varpi^m)(\chi)\} \in \{0, 1, \ldots, \infty\}$ and $X = \mathrm{End}_{\mathcal{O}}(T)(\chi) \otimes_{\mathcal{O}} K/\mathcal{O}$. Then $X[\varpi^m] = \mathrm{End}(T/\varpi^m)(\chi)$, $X^G[\varpi^m] = M_m \simeq \mathcal{O}/\varpi^{\min(m,h)}$, and X^G has length h; if $h < \infty$, $X^G \simeq \mathcal{O}/\varpi^h$. If $h = \infty$, then $T \simeq T(\chi)$ (no completeness of $\mathcal{O}$ is needed).

(iv) If $n \in \mathcal{O}^\times$ and $\bar\chi \neq 1$, the same holds for $\mathrm{ad}^0 T(\chi) \otimes K/\mathcal{O}$: $(\mathrm{ad}^0 T(\chi) \otimes K/\mathcal{O})^G = X^G$.

(v) If $T/\varpi^m \simeq (T/\varpi^m)(\chi)$ then $\chi^n \equiv 1 \pmod{\varpi^m}$ on G. In particular, if $n = 2$, $\mathcal{O} = \mathbb{Z}_\ell$ with ℓ odd and $\chi(G) = \mathbb{Z}_\ell^\times$, then $h = 0$ for $\ell \geq 5$ and $h \leq 1$ for $\ell = 3$.

Proof. (i) T/ϖ^m is free over $\mathcal{O}/\varpi^m$, so its ϖ^{m-1}-torsion is $\varpi(T/\varpi^m)$; this gives the first statement. If $\varpi\phi = 0$, then ϕ kills $\varpi(T/\varpi^m)$ and takes values in the ϖ-torsion $\varpi^{m-1}T/\varpi^m T$, which multiplication by ϖ^{m-1} identifies with $\bar T$ (with the twist by $\bar\chi$ for the target); so $M_m[\varpi] \simeq \mathrm{Hom}_G(\bar T, \bar T(\bar\chi))$, of dimension at most one by Lemma 4.49 ($\bar T(\bar\chi)$ is absolutely irreducible). M_m is a finitely generated $\mathcal{O}/\varpi^m$-module whose ϖ-torsion has length at most one, hence cyclic: by the structure theorem (Chapter 3) $M_m \simeq \bigoplus_i \mathcal{O}/\varpi^{a_i}$ with $1 \leq a_i \leq m$, its ϖ-torsion is $\bigoplus_i \varpi^{a_i-1}\mathcal{O}/\varpi^{a_i}$, of length equal to the number of summands, so there is at most one summand. (ii) By (i), $\phi \bmod \varpi$ is a nonzero G-map $\bar T \to \bar T(\bar\chi)$, an isomorphism by Schur. So ϕ is surjective modulo ϖ, hence surjective by Nakayama, hence bijective, the two modules having the same finite length. Conversely, an isomorphism is nonzero modulo ϖ. (iii) $X[\varpi^m] = \mathrm{End}(T)(\chi) \otimes \varpi^{-m}\mathcal{O}/\mathcal{O} \simeq \mathrm{End}(T/\varpi^m)(\chi)$, and taking invariants gives M_m. Let $M_m \simeq \mathcal{O}/\varpi^j$ with generator ϕ. If $j = m$, ϕ is an isomorphism by (ii), so $m \leq h$. In general $\varpi^j\phi = 0$ means that ϕ takes values in $\varpi^{m-j}(T/\varpi^m)$, so $\phi = \varpi^{m-j}\phi'$ for a G-map $\phi' : T/\varpi^j \to (T/\varpi^j)(\chi)$ (defined by dividing the values by ϖ^{m-j}, well defined modulo ϖ^j), with $\varpi^{j-1}\phi' \neq 0$ because $\varpi^{j-1}\phi \neq 0$. By (ii) ϕ' is an isomorphism, so $j \leq h$. Conversely, for $m \leq h$ the reduction of an isomorphism at a level $\geq m$ is an isomorphism at level m, which generates $M_m \simeq \mathcal{O}/\varpi^m$ by (ii); and for $m > h$ with h finite, if ψ is an isomorphism at level h and $\tilde\psi \in \mathrm{End}_\mathcal{O}(T)$ lifts it, then $x \mapsto \varpi^{m-h}\tilde\psi(x) \bmod \varpi^m$ is an element of M_m (it is G-equivariant because $\tilde\psi g - \chi(g) g\tilde\psi$ has values in $\varpi^h T$) of exact order ϖ^h. Hence $j = \min(m, h)$, and $X^G = \bigcup_m X^G[\varpi^m]$ has length h, and equals $X^G[\varpi^h] \simeq \mathcal{O}/\varpi^h$ when h is finite.

Now let $h = \infty$. *Compatible isomorphisms.* The reduction map $M_{m+1} \to M_m$ is surjective: M_{m+1} contains an isomorphism, whose reduction is an isomorphism at level m and so generates M_m by (ii). Choose an isomorphism $\phi_1 \in M_1$ and, inductively, $\phi_{m+1} \in M_{m+1}$ reducing to ϕ_m. Each ϕ_m reduces modulo ϖ to $\phi_1 \neq 0$, so $\varpi^{m-1}\phi_m \neq 0$ by (i), and ϕ_m is an isomorphism by (ii). *Passage to the completion.* Let $\widehat{\mathcal{O}} = \varprojlim \mathcal{O}/\varpi^m$ be the ϖ-adic completion, a discrete valuation ring with uniformiser ϖ and $\widehat{\mathcal{O}}/\varpi^m = \mathcal{O}/\varpi^m$, containing $\mathcal{O}$, with fraction field $\widehat{K} \supseteq K$ (for $\mathcal{O} = \mathbb{Z}_\ell$ nothing changes). In a basis of T, the matrices of the ϕ_m are compatible, so they define a matrix $\hat\phi \in \mathrm{M}_n(\widehat{\mathcal{O}})$ with $\hat\phi \equiv \phi_m \pmod{\varpi^m}$ for all m. For $g \in G$, every entry of $\hat\phi\rho(g) - \chi(g)\rho(g)\hat\phi$ lies in $\varpi^m\widehat{\mathcal{O}}$ for all m, hence is 0; and $\hat\phi \neq 0$ since $\hat\phi \equiv \phi_1 \pmod{\varpi}$. So $\mathrm{Hom}_{\widehat{K}[G]}(V_{\widehat{K}}, V_{\widehat{K}}(\chi)) \neq 0$, where $V = T \otimes_\mathcal{O} K$. *Descent.* By Proposition 4.7(i) for the field extension $\widehat{K}/K$, $\mathrm{Hom}_{K[G]}(V, V(\chi)) \neq 0$. Let x be a nonzero element. Multiplying x by a power of ϖ, we may assume that $x(T) \subseteq T$ and $x(T) \not\subseteq \varpi T$ (the entries of its matrix lie in $\mathcal{O}$, not all in $\varpi\mathcal{O}$). Then $\bar x = x \bmod \varpi$ is a nonzero G-map $\bar T \to \bar T(\bar\chi)$ between irreducible representations, an isomorphism by Theorem 4.10(i). So $\det x \in \mathcal{O}$ has nonzero reduction, $\det x \in \mathcal{O}^\times$, and x is an isomorphism $T \simeq T(\chi)$ of $\mathcal{O}[G]$-modules. (iv) $\mathrm{End}(T) = \mathrm{ad}^0 T \oplus \mathcal{O}$ (Proposition 4.52(i)), and $(K/\mathcal{O}(\chi))^G = 0$ because $\chi(g) - 1$ is a unit for some g; so the $\mathcal{O}$-summand contributes nothing. (v) Determinants (Proposition 4.48(iv) modulo ϖ^m). For the last statement, $\chi^2 \equiv 1 \pmod{\ell^m}$ on G means $x^2 \equiv 1 \pmod{\ell^m}$ for every $x \in \mathbb{Z}_\ell^\times$; with $x = 2$, $\ell^m \mid 3$, so $m = 0$ for $\ell \geq 5$ and $m \leq 1$ for $\ell = 3$ (Chapter 2). □

In the paper 4.82. Lemma lem:h0 with $G = G_\mathbb{Q}$, $\mathcal{O} = \mathbb{Z}_\ell$, $T = T_\ell E$, $\chi = \chi_\ell$: $W^D = \mathrm{ad}^0 T(1) \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$, and by (iv) and (iii), $H^0(\mathbb{Q}, W^D)$ has length $h_\ell(E)$, "the largest k such that $\rho \bmod \ell^k \simeq$

$(\rho \otimes \chi_\ell) \bmod \ell^k$", and is cyclic when this is finite. Absolute irreducibility of $\bar\rho$ comes from complex conjugation (Proposition 4.13), $\bar\chi_\ell \neq 1$ for ℓ odd, and $\chi_\ell(G_\mathbb{Q}) = \mathbb{Z}_\ell^\times$ (Chapter 5); so (v) gives $h_\ell(E) = 0$ for $\ell \geq 5$ and $h_3(E) \leq 1$ (in particular $H^0(\mathbb{Q}, W^D)$ is finite and cyclic), with equality iff $\bar\rho \simeq \bar\rho \otimes \bar\chi_3 = \bar\rho \otimes \chi_{-3}$, for every E with $\bar\rho$ irreducible, with or without complex multiplication. In Lemma lem:h0, "a submodule of $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)^3$ with ℓ-torsion of rank at most one, is finite cyclic or isomorphic to $\mathbb{Q}_\ell/\mathbb{Z}_\ell$" is (iii), and the determinant bound (v) excludes the second case. Remark rem:ns and Section sec:anomaly use $h_3(E) = 1$ for the image 3Ns (Theorem 4.66).

4.11 The mod ℓ world: a foretaste, and Dickson's list

This last section reads the chapter's results in the setting of the paper: a continuous representation $\bar\rho\colon G_\mathbb{Q} \to \mathrm{GL}_2(\mathbb{F}_\ell)$ has finite image, so everything above applies to it, and the Galois input needed is collected in Chapter 5 and Chapter 11. It also records Dickson's classification, which organises the possible images.

Remark 4.83 (The mod ℓ dictionary). Let $\bar\rho\colon G_\mathbb{Q} \to \mathrm{GL}_2(\mathbb{F}_\ell)$ be continuous, ℓ odd, with $\det\bar\rho = \bar\chi_\ell$ (as for $\bar\rho_{E,\ell}$, Chapter 9).

(i) Complex conjugation c has $\bar\rho(c)^2 = 1$ and $\det\bar\rho(c) = \bar\chi_\ell(c) = -1$, so $\bar\rho$ is irreducible iff it is absolutely irreducible (Proposition 4.13).

(ii) The hypothesis of Theorem thm:main concerns $\mathrm{Res}_H\,\bar\rho$ for the subgroup $H = G_{\mathbb{Q}(\sqrt{\ell^*})}$ of index 2, with $\chi_H = \chi_{\ell^*} = \bar\chi_\ell^{(\ell-1)/2}$. If $\bar\rho$ is reducible, so is $\mathrm{Res}_H\,\bar\rho$, and the hypothesis fails. If $\bar\rho$ is irreducible, it is absolutely irreducible by (i), and Theorem 4.44 applies: the hypothesis fails iff $\bar\rho \simeq \bar\rho \otimes \chi_{\ell^*}$, iff $\bar\rho \otimes \overline{\mathbb{F}}_\ell$ is induced from a character of H. Irreducibility cannot be dropped here: for $\ell \geq 5$, $\bar\rho = \mathbf{1} \oplus \bar\chi_\ell$ has reducible restriction to H, but $\bar\rho \otimes \chi_{\ell^*} = \chi_{\ell^*} \oplus \bar\chi_\ell^{(\ell+1)/2} \not\simeq \bar\rho$ (its constituents are not $\mathbf{1}$, as $\chi_{\ell^*} \neq 1$ and $\bar\chi_\ell^{(\ell+1)/2} \neq 1$ for $\ell \geq 5$), and $\bar\rho \otimes \overline{\mathbb{F}}_\ell$ is not induced from H (Proposition 4.41: an induced representation is isomorphic to its twist by χ_H).

(iii) Lemma lem:h0 concerns $\bar\rho \simeq \bar\rho \otimes \bar\chi_\ell$, which forces $\bar\chi_\ell^2 = 1$ (Proposition 4.48(iv)), that is $\ell = 3$; there $\bar\chi_3 = \chi_{-3} = \det\bar\rho$ and Theorem 4.66 applies. For $\ell \geq 5$ the two conditions differ: for $\bar\rho = \bar\rho_{E,\ell}$, $\bar\rho \simeq \bar\rho \otimes \chi_{\ell^*}$ can occur (only when $\ell \mid N$, by Proposition prop:Sf), while $\bar\rho \simeq \bar\rho \otimes \bar\chi_\ell$ never does.

(iv) The objects of the paper and where they are built:

object	meaning	here
$V = V_\ell E$, ρ	two-dimensional $\mathbb{Q}_\ell$-representation of $G_\mathbb{Q}$	Definition 4.2
$T = T_\ell E$	a $G_\mathbb{Q}$-stable lattice in V	Definition 4.74
$\bar\rho$, $\rho \bmod \ell^k$	$T/\ell T$, $T/\ell^k T$	Proposition 4.76, Proposition 4.81
$A_f = \mathrm{ad}^0 V$	trace-zero adjoint	Definition 4.51, Proposition 4.52
$A = \mathrm{ad}^0 T$	adjoint lattice, a direct summand of $\mathrm{End}(T)$	Proposition 4.75(iii)
$T^D = \mathrm{Hom}(A, \mathbb{Z}_\ell(1)) \simeq A(1)$	Kummer dual, via the trace form	Proposition 4.58
$W = A \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$, $W^D = A(1) \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell$	discrete coefficients	Proposition 4.81(iii), (iv)
$H^0(\mathbb{Q}, W^D)$, $h_\ell(E)$	twisted self-isomorphisms of $\rho \bmod \ell^k$	Proposition 4.81
$\mathrm{ad}^0 M_{f,\lambda} = \mathrm{ad}^0 T$	adjoint of a dual, twisted lattice	Proposition 4.60

Theorem 4.84 (Dickson)**.** *Let ℓ be an odd prime and $G \le \mathrm{GL}_2(\mathbb{F}_\ell)$, with image P in $\mathrm{PGL}_2(\mathbb{F}_\ell)$. If $\ell \mid \#G$, then $G \supseteq \mathrm{SL}_2(\mathbb{F}_\ell)$ or G lies in a Borel subgroup. If $\ell \nmid \#G$, then P is cyclic (and G lies in a Cartan subgroup), or dihedral (and G lies in the normaliser of a Cartan subgroup, not in the Cartan subgroup), or P is isomorphic to A_4, S_4 or A_5.*

Proof. We do not prove this; see [171, Section 2] and Chapter 1, where the statement is the same and the case $\ell = 3$ is checked by enumeration. □

For an absolutely irreducible $\bar\rho$ with projective image P, Proposition 4.46 reads Dickson's list as follows: P is never cyclic; P is dihedral iff $\bar\rho \otimes \overline{\mathbb{F}}_\ell$ is induced from a subgroup of index 2; the exceptional images A_4, S_4, A_5 and the large images ($P \supseteq \mathrm{PSL}_2(\mathbb{F}_\ell)$) are not induced (for $\ell \ge 5$, $\mathrm{PSL}_2(\mathbb{F}_\ell)$ is simple and non-abelian, so it is not contained in a dihedral group, whose subgroups are cyclic or dihedral). At $\ell = 3$: $\mathrm{GL}_2(\mathbb{F}_3) \mapsto S_4$, $N_{ns}(\mathbb{F}_3) \mapsto D_4$, $N_s(\mathbb{F}_3) \mapsto V_4$ (Proposition 4.62). The subgroup $N_s(\mathbb{F}_3)$ is not a maximal subgroup of $\mathrm{GL}_2(\mathbb{F}_3)$: it has index 2 in $N_{ns}(\mathbb{F}_3)$ (Chapter 1).

4.12 Exercises

Exercise 4.85. Show that $C_4 = \langle J \rangle$ acting on $\mathbb{F}_3^2$ is irreducible but not absolutely irreducible, that its commutant $\mathbb{F}_3[J]$ is a field with 9 elements, and decompose $\mathbb{F}_9^2$ into eigenlines of J. Which eigenline is spanned by a vector with coordinates in $\mathbb{F}_3$? *Hint.* $X^2 + 1$ has no root in $\mathbb{F}_3$, since $0, 1, 2$ have squares $0, 1, 1$; the commutant is $\mathbb{F}_3[J] \simeq \mathbb{F}_3[X]/(X^2+1)$ by Lemma 4.70. Over $\mathbb{F}_9$ the eigenlines are $\mathbb{F}_9(1, i)^t$ and $\mathbb{F}_9(1, -i)^t$. Neither contains a nonzero vector of $\mathbb{F}_3^2$: such a vector would be an eigenvector of J with eigenvalue $\pm i \notin \mathbb{F}_3$.

Exercise 4.86. Prove directly (without Theorem 4.10) that every absolutely irreducible representation of a finite abelian group is one-dimensional. Show that $C_{ns}(\mathbb{F}_3) = \langle a \rangle \simeq C_8$ gives an irreducible two-dimensional representation of C_8 over $\mathbb{F}_3$, and determine all irreducible representations of C_8 over $\mathbb{F}_3$ (their degrees and their number). *Hint.* Commuting operators on a nonzero finite-dimensional space over $\bar k$ have a common eigenvector: an eigenspace of one is stable under the others; induct on the dimension. For C_8: as $3 \nmid 8$, $\mathbb{F}_3[C_8] \simeq \mathbb{F}_3[X]/(X^8 - 1)$ is the product of the fields $\mathbb{F}_3[X]/(f)$ over the irreducible factors f of $X^8 - 1$, and these fields

are the irreducible representations. The roots of X^8-1 are the elements of $\mathbb{F}_9^\times$, and over $\mathbb{F}_3$, $X^8-1=(X-1)(X+1)(X^2+1)(X^2+X+2)(X^2-X+2)$; so there are 5 irreducible representations, two of degree 1 and three of degree 2. That of $\langle a\rangle$ is the one for X^2+X+2, the characteristic polynomial X^2-2X+2 of a.

Exercise 4.87. Show that the standard representation of $\mathrm{U}=\langle u\rangle$ on $\mathbb{F}_3^2$ is indecomposable but not irreducible, and that $\mathbb{F}_p[C_p]$ is uniserial. Why does this not contradict Maschke's theorem? Show that every representation of C_p over $\mathbb{F}_p$ is a direct sum of the quotients $\mathbb{F}_p[x]/(x-1)^j$, $1\le j\le p$. *Hint.* There is no contradiction: $\#\mathrm{U}=3$ is the characteristic. With $y=x-1$, a representation of C_p over $\mathbb{F}_p$ is a finitely generated $\mathbb{F}_p[y]$-module killed by $y^p=x^p-1$; apply the structure theorem over the principal ideal domain $\mathbb{F}_p[y]$ (Chapter 3). Each summand $\mathbb{F}_p[y]/(y^j)$ is uniserial, its subrepresentations being the $y^i\mathbb{F}_p[y]/(y^j)$, $0\le i\le j$.

Exercise 4.88. Give two non-isomorphic semisimple representations of C_2 over $\mathbb{F}_3$ with the same trace function. Show that two two-dimensional representations with the same determinant and the same trace function have isomorphic semisimplifications, in every characteristic. *Hint.* Example 4.32; then Theorem 4.35, since the characteristic polynomial of a 2×2 matrix is $X^2-\mathrm{tr}(g)X+\det(g)$.

Exercise 4.89. Check the claim of Proposition prop:ns that the determinant-one subgroup C_4 of $N_s(\mathbb{F}_3)$ acts on $\mathbb{F}_9^2$ as $\psi\oplus\psi^{-1}$ with ψ of order 4, and that the standard representation of $N_s(\mathbb{F}_3)$ over $\mathbb{F}_9$ is isomorphic to $\mathrm{Ind}_{C_4}^{N_s}\psi$: compute the matrices of J and σ in the basis $v=(1,i)^t$, σv. Show that over $\mathbb{F}_3$ it is not induced from a character of C_4, and that it is nevertheless isomorphic over $\mathbb{F}_3$ to its twist by det. *Hint.* Example 4.14 and Proposition 4.63. A character of C_4 with values in $\mathbb{F}_3^\times=\{\pm1\}$ sends J to ±1; if ρ were induced from it over $\mathbb{F}_3$, $\mathrm{Res}_{C_4}\rho$ would contain a line on which J acts by ±1, but J has no eigenvalue in $\mathbb{F}_3$. For the twist, check $J\rho(g)=\det(g)\rho(g)J$ on the generators J and σ.

Exercise 4.90. Check the claim of Proposition prop:ns that Q_8 and $\mathrm{SL}_2(\mathbb{F}_3)$ act absolutely irreducibly on $\mathbb{F}_3^2$ in two ways: by Maschke's theorem (Proposition 4.26) and by the commutator argument (a subgroup of a Borel subgroup of $\mathrm{GL}_2(\overline{\mathbb{F}}_3)$ has abelian commutator subgroup of exponent dividing 3). Explain why "non-abelian and faithful" does not suffice, using $\mathrm{B}(\mathbb{F}_3)$. *Hint.* The commutator $xyx^{-1}y^{-1}$ of two upper triangular matrices is upper triangular with diagonal entries $1,1$, so the commutator subgroup of a Borel subgroup of $\mathrm{GL}_2(\overline{\mathbb{F}}_3)$ lies in $\{\left(\begin{smallmatrix}1&b\\0&1\end{smallmatrix}\right)\}\simeq(\overline{\mathbb{F}}_3,+)$, abelian of exponent 3. The commutator subgroup of Q_8 is $\{\pm1\}$, and -1 is not unipotent; that of $\mathrm{SL}_2(\mathbb{F}_3)$ is Q_8, which is not abelian (Chapter 1). $\mathrm{B}(\mathbb{F}_3)$ is non-abelian, acts faithfully, and fixes the line $\mathbb{F}_3e_1$.

Exercise 4.91. Show that the standard representation of $N_s(\mathbb{F}_3)$ is isomorphic to its twist by each of the three nontrivial characters of $N_s(\mathbb{F}_3)/\{\pm1\}$, with intertwiners J, σ, w, and that these intertwiners have trace 0. Show that the standard representation of $N_{ns}(\mathbb{F}_3)$ is induced, over $\mathbb{F}_9$, from $C_{ns}(\mathbb{F}_3)$, but is not isomorphic to its twist by det. Which of the two satisfies the hypothesis "absolutely irreducible on the determinant-one subgroup"? *Hint.* Proposition 4.63(iii), (iv) and Proposition 4.64. The hypothesis holds for $N_{ns}(\mathbb{F}_3)$, whose determinant-one subgroup Q_8 acts absolutely irreducibly, and fails for $N_s(\mathbb{F}_3)$, whose determinant-one subgroup C_4 does not.

Exercise 4.92. Check the claim of Lemma lem:h0 that an isomorphism $\phi\colon\bar\rho\to\bar\rho\otimes\chi_{-3}$ has trace 0. More generally, show that $(\mathrm{ad}^0V\otimes\chi)^G=\mathrm{Hom}_G(V,V\otimes\chi)$ for every nontrivial character χ when $\dim V$ is invertible in k, and give an example with $\chi=1$ where the two spaces differ. *Hint.*

Lemma 4.49 with g such that $\chi_{-3}(g) = -1$, as $1-(-1) = 2 \neq 0$ in $\mathbb{F}_3$; then Proposition 4.54(ii), (iii). For $\chi = 1$, $\mathrm{Hom}_G(V,V)$ contains id_V, of trace $\dim V \neq 0$, which is not in $(\mathrm{ad}^0 V)^G$; for instance, for $V = k$ with trivial action, $\mathrm{Hom}_G(V,V) = k$ and $\mathrm{ad}^0 V = 0$.

Exercise 4.93. Let $H \leq G$ have index 2, $\mathrm{char}\, k \neq 2$, and V absolutely irreducible of dimension 2. Prove that $V \simeq V \otimes \chi_H$ iff $\mathrm{tr}\,\rho(g) = 0$ for all $g \notin H$. (For "if", compare traces and determinants of V and $V \otimes \chi_H$ and use Corollary 4.36.) Deduce again that the standard representation of $\mathrm{GL}_2(\mathbb{F}_3)$ is not isomorphic to its twist by det, and that that of $N_s(\mathbb{F}_3)$ is.

Exercise 4.94. Prove $\mathrm{ad}^0 V \simeq \mathrm{Sym}^2 V \otimes \det^{-1}$ for $\dim V = 2$ by the explicit map Ξ of Proposition 4.56, and show that over $\mathbb{Z}$ the image of $\mathrm{Sym}^2 \mathbb{Z}^2$ has index 4 in $\mathrm{ad}^0 \mathbb{Z}^2$. Deduce the eigenvalues α/β, 1, β/α of $\mathrm{Ad}\, g$ on $\mathrm{ad}^0 V$ from the eigenvalues $\alpha^2, \alpha\beta, \beta^2$ of $\mathrm{Sym}^2 g$. *Hint.* In the bases e_1^2, e_1e_2, e_2^2 and e, h, f the matrix of Ξ is $\mathrm{diag}(-2,1,2)$, and the image of a map $\mathbb{Z}^3 \to \mathbb{Z}^3$ with nonzero determinant has index equal to the absolute value of the determinant. On $\mathrm{Sym}^2 V \otimes \det^{-1}$ the eigenvalues are $\alpha^2, \alpha\beta, \beta^2$ divided by $\alpha\beta$.

Exercise 4.95. Compute the Gram matrix of the trace form on $\mathrm{ad}^0 \mathbb{Z}_\ell^2$ in the basis e, h, f, and check the identification $T^D = \mathrm{Hom}(A, \mathbb{Z}_\ell(1)) \simeq A(1)$ of the paper's Section 4.2 for ℓ odd. What goes wrong for $\ell = 2$? Is the trace form on all of $\mathrm{End}(\mathbb{Z}_2^2)$ perfect? *Hint.* Proposition 4.58(ii), (iii): the Gram matrix has determinant -2, a unit in $\mathbb{Z}_\ell$ for ℓ odd. For $\ell = 2$, $B(x,h) = 2\beta$ is even for every $x = \alpha e + \beta h + \gamma f \in \mathrm{ad}^0 \mathbb{Z}_2^2$, so the linear form taking the values $0, 1, 0$ on e, h, f is not of the form $B(x,-)$, and $A \to A^\vee$ is not onto. On $\mathrm{End}(\mathbb{Z}_2^2)$ the Gram matrix in the basis (E_{ij}) is a permutation matrix, so the trace form there is perfect: the defect comes from restricting to trace zero.

Exercise 4.96. Check the formulas in the proof of Lemma lem:tamfactor: for $t = 1 + n'e$, $(t-1)e = 0$, $(t-1)h = -2n'e$, $(t-1)f = n'h - n'^2 e$; and for $F = \left(\begin{smallmatrix} \varepsilon q & c' \\ 0 & \varepsilon \end{smallmatrix}\right)$ with $\varepsilon = \pm 1$, $FeF^{-1} = qe$ and $FhF^{-1} = h - 2c'\varepsilon e$. Deduce that for ℓ odd $(t-1)\,\mathrm{ad}^0 T = n'(\mathbb{Z}_\ell e \oplus \mathbb{Z}_\ell h)$. *Hint.* Proposition 4.52(iii), with $\varepsilon^{-1} = \varepsilon$. The submodule $(t-1)\,\mathrm{ad}^0 T$ is generated by $(t-1)e = 0$, $(t-1)h = -2n'e$ and $(t-1)f = n'h - n'^2 e$; it lies in $n'(\mathbb{Z}_\ell e \oplus \mathbb{Z}_\ell h)$, and since $2 \in \mathbb{Z}_\ell^\times$ it contains $n'e$, hence also $n'h$.

Exercise 4.97. For $g = -1$, $g = \left(\begin{smallmatrix} 0 & -1 \\ 1 & -1 \end{smallmatrix}\right)$ (order 3), $g = J$ (order 4), $g = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ (order 6), $g = u$ and $g = -u$ in $\mathrm{SL}_2(\mathbb{Z})$, compute $\dim V^g$ and $\dim(\mathrm{ad}^0 V)^g$ for $V = \mathbb{Q}^2$ and for $V = \mathbb{F}_3^2$, and a generator of $(\mathrm{ad}^0 V)^g$. Check the claims of Lemma lem:IV and Remark rem:types about $E[3]^{I_q}$. *Answer.* Over $\mathbb{Q}$: for -1, $\dim V^g = 0$ and $(\mathrm{ad}^0 V)^g = \mathrm{ad}^0 V$; for the elements of order 3, 4, 6, $\dim V^g = 0$ and $(\mathrm{ad}^0 V)^g$ is the line spanned by $2g+1$, J, $2g-1$ respectively (the first and the last are both $\left(\begin{smallmatrix} 1 & -2 \\ 2 & -1 \end{smallmatrix}\right)$); for u, $\dim V^u = 1$ and $(\mathrm{ad}^0 V)^u = \mathbb{Q}e$; for $-u$, $\dim V^{-u} = 0$ and $(\mathrm{ad}^0 V)^{-u} = \mathbb{Q}e$. Over $\mathbb{F}_3$ the only change is for the element of order 3, whose reduction is a nontrivial unipotent: $\dim V^g = 1$ (Proposition 4.72(ii)). The generators of $(\mathrm{ad}^0 V)^g$ over $\mathbb{F}_3$ are the reductions of those over $\mathbb{Q}$. These values were checked in PARI/GP.

Exercise 4.98. Let $u \neq 1$ be unipotent and $FuF^{-1} = u^q$. Show that F acts on $(\mathrm{ad}^0 V)^u$ by q. Explain why the factor $1 - q^{-1-s}$ of $L_q(A_f, s)^{-1}$ at a multiplicative prime requires the geometric Frobenius F^{-1}, and why at the primes of types II, III, IV and their duals the choice of Frobenius does not matter. *Hint.* Proposition 4.69(iii). The factor is $\det(1 - F^{-1}q^{-s} \mid (\mathrm{ad}^0 V)^I)$, and F^{-1} acts on the line by q^{-1}, which gives $1 - q^{-1-s}$; with F one would get $1 - q^{1-s}$. For the types II, III, IV and their duals, F acts by ± 1 (Proposition 4.71(iii)), which is its own inverse.

Exercise 4.99. Show that for a finite group of order prime to ℓ acting on a $\mathbb{Z}_\ell$-lattice T, invariants commute with reduction modulo ℓ^m. Show that this fails for $g \in \mathrm{SL}_2(\mathbb{Z}_3)$ of order 3 acting on $T = \mathbb{Z}_3^2$ (Lemma lem:IV), although it holds for the invariants of g on $\mathrm{ad}^0 T$. Does it hold for g of order 6 on T? On $\mathrm{ad}^0 T$? *Hint.* Theorem 4.18(ii) and Proposition 4.72. For g of order 6, $T^g = 0 = (T/3T)^g$, so it holds on T; on $\mathrm{ad}^0 T$, g acts as $-g$, of order 3, and the case of order 3 applies: it holds.

Exercise 4.100. Let $G \subseteq \mathrm{GL}_2(\mathbb{Z}_\ell)$ be the closed subgroup generated by $t = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. Show that the lattices $L_k = \mathbb{Z}_\ell e_1 \oplus \ell^k \mathbb{Z}_\ell e_2$, $k \geq 0$, are G-stable and pairwise non-homothetic, that their reductions have the same semisimplification, and that the reduction of L_k is split iff $k \geq 1$. Explain why this does not contradict Theorem 4.77, and prove that theorem again in your own words. *Hint.* In the basis $e_1, \ell^k e_2$ of L_k the matrix of t is $\left(\begin{smallmatrix} 1 & \ell^k \\ 0 & 1 \end{smallmatrix}\right)$. If $L_k = \ell^m L_j$, intersect with $\mathbb{Q}_\ell e_1$: $\mathbb{Z}_\ell e_1 = \ell^m \mathbb{Z}_\ell e_1$, so $m = 0$, and then $k = j$. The theorem does not apply because the reduction of L_0 is reducible.

Exercise 4.101. Let T be free of rank 2 over $\mathbb{Z}_\ell$, ℓ odd, with an action of a group G such that $T/\ell T$ is absolutely irreducible, and let $\chi\colon G \to \mathbb{Z}_\ell^\times$ be surjective. Show that $\mathrm{Hom}_G(T/\ell^m, (T/\ell^m)(\chi))$ is cyclic for every m, that $H^0(G, \mathrm{ad}^0 T(\chi) \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell)$ is finite of length at most 1, and that it is 0 unless $\ell = 3$ (the corrected Lemma lem:h0). For $\ell = 3$, show that the length is 1 iff $T/3T \simeq (T/3T)(\bar\chi)$. *Hint.* Proposition 4.81 with $\mathcal{O} = \mathbb{Z}_\ell$: (i) gives the cyclicity; (iv) applies because $\bar\chi$ maps onto $\mathbb{F}_\ell^\times \neq 1$; (v) gives $h = 0$ for $\ell \geq 5$ and $h \leq 1$ for $\ell = 3$; and for $\ell = 3$, $h \geq 1$ iff $T/3T \simeq (T/3T)(\bar\chi)$, by the definition of h.

4.13 Notes and references

The representation theory of finite groups over $\mathbb{C}$ in Section 4.1 to Section 4.4 follows [173]: Maschke's theorem is in its Section 1.3, Schur's lemma in Section 2.2, the orthogonality relations in Sections 2.3 to 2.5, the divisibility of degrees in Section 6.5, induction, Frobenius reciprocity and Mackey's criterion in Sections 7.1 to 7.4, Clifford's theorem in Section 8.1, and the Frobenius-Schur indicator in Section 13.2. These section numbers are recalled, not checked against a printed copy, and should be read as pointers; no theorem number of [173] is relied upon. The proofs of Schur's lemma, Maschke's theorem and Frobenius reciprocity given here are characteristic-free, as is the averaging proof of $\dim \mathrm{Hom}_G(V, W) = \langle \mathrm{tr}_W, \mathrm{tr}_V \rangle$. The treatment of representations over arbitrary fields (absolute irreducibility, extension of scalars, the density theorem, the theorem of Brauer and Nesbitt, the Noether-Deuring theorem) is classical and can be found in [37], Sections 27 to 30 and 29 for Noether-Deuring, and in [109, Chapter XVII], where semisimple modules and the density theorem are treated; again these are unverified pointers. The proof of Brauer-Nesbitt in Section 4.5 is the standard one by reduction to an algebraically closed field, cancellation, and the Frobenius $f \mapsto f^p$; the reduction step uses only the density theorem, so no perfectness of k is needed. The criterion Proposition 4.12(iv), that an irreducible representation with commutant k is absolutely irreducible over every field, is a consequence of the same density theorem. Riley-Hobson-Bence [165] treats character tables over $\mathbb{C}$ in its chapter on representation theory (Chapter 29 of the third edition; an unverified pointer); [58, Chapter 18] is an algebraic introduction at the same level.

Clifford theory for a subgroup of index 2 (Theorem 4.44) and the characterisation of dihedral representations (Proposition 4.46) are standard; for the Galois representations of elliptic curves they go back to [171, Section 2], which also contains the classification of subgroups of $\mathrm{GL}_2(\mathbb{F}_\ell)$

stated as Theorem 4.84 (Propositions 15 and 16 there, as in Chapter 1). Lattices in ℓ-adic representations, their reductions and the independence of $\bar{\rho}^{ss}$ from the lattice are in [178, Chapter I]; the homothety lemma Theorem 4.77 is the elementary half of that circle of ideas, and the converse construction is Ribet's lemma [157, Section 2], where it appears as a proposition about reducible residual representations (we recall it as Proposition 2.1 but have not checked the number). The use of Brauer-Nesbitt together with Chebotarev for Galois representations, as in Lemma lem:old, is standard; see [38] and Chapter 5.

The table of Proposition 4.62 and the facts of Proposition 4.63 and Proposition 4.64 were computed by hand and checked by enumerating $\mathrm{GL}_2(\mathbb{F}_3)$ with the script of Section 4.8 and with an independent Python enumeration (stable lines over $\mathbb{F}_3$ and $\mathbb{F}_9$, commutants, intertwiners, projective images). The formulas of Proposition 4.52(iii), the map Ξ of Proposition 4.56 and the Gram matrix of Proposition 4.58 were checked symbolically in PARI/GP [148], and the fixed spaces of Section 4.9 on the six integral matrices of Exercise 4.97 over $\mathbb{Q}$ and over $\mathbb{F}_3$.

Part II

Number fields and local fields

Chapter 5

Galois theory, finite and infinite

This chapter builds Galois theory from the definition of a field extension to the absolute Galois group $G_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$, its continuous representations and the Chebotarev density theorem. The paper uses it in five places: the hypothesis of Theorem thm:main (absolute irreducibility on $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell^*}))$), Proposition prop:ns (the determinant cuts out $\mathbb{Q}(\sqrt{-3})$, and the 3-division polynomial factors according to the orbits on the four lines), Lemma lem:old (Chebotarev and Brauer-Nesbitt), Lemmas lem:tamagawa-exp and lem:tamfactor (Kummer theory and the Kummer cocycle), and Lemma lem:h0 (the cyclotomic character χ_ℓ against the quadratic character χ_{ℓ^*}). Group theory, profinite groups, rings, finite fields and representation theory are taken from Chapter 1, Chapter 2, Chapter 3 and Chapter 4; prime ideals and Frobenius elements in number fields are Chapter 6, local fields Chapter 7.

Core results at a glance

Throughout, F is a field, $\overline{\mathbb{F}}$ an algebraic closure, $F^{\mathrm{sep}} \subseteq \overline{\mathbb{F}}$ the separable closure and $G_F = \mathrm{Gal}(F^{\mathrm{sep}}/F)$; $\overline{\mathbb{Q}} \subset \mathbb{C}$ is the field of algebraic numbers, $G_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ and $G_K = \mathrm{Gal}(\overline{\mathbb{Q}}/K)$ for $K \subseteq \overline{\mathbb{Q}}$; ℓ is a prime, $\ell^* = (-1)^{(\ell-1)/2}\ell$ for odd ℓ; $\mathcal{O}$ is the ring of integers of a finite extension of $\mathbb{Q}_\ell$, with uniformiser ϖ and maximal ideal $\lambda = \varpi\mathcal{O}$.

5.1 Conventions. Automorphisms compose as maps, $(\sigma\tau)(x) = \sigma(\tau(x))$; Frob_q is $x \mapsto x^q$ on $\overline{\mathbb{F}}_q$ and Frob_p an arithmetic Frobenius, so $\chi_\ell(\mathrm{Frob}_p) = p$; χ_d ($d \in \mathbb{Q}^\times$ a non-square) is the character of $\mathbb{Q}(\sqrt{d})$, χ_{q^*} that of conductor q (never χ_q); χ_ℓ is the ℓ-adic cyclotomic character, $\bar{\chi}_\ell$ its reduction, χ_3^{cyc} at the prime 3; Kummer characters take values in μ_n; $\mathbb{Z}_\ell(1) = \varprojlim \mu_{\ell^k}$. Conventions 5.1 to 5.4.

5.2 Extensions and the tower law (definition and proposition). $[L : F] = \dim_F L$; for $F \subseteq L \subseteq M$, $[M : F] = [M : L][L : F]$, products of bases being bases. *(proved here)* Definition 5.5, Proposition 5.6.

5.3 Minimal polynomial. If α is algebraic over F, the kernel of $F[x] \to L$, $x \mapsto \alpha$, is generated by a unique monic irreducible $m_{\alpha,F}$; $F(\alpha) = F[\alpha] \simeq F[x]/(m_{\alpha,F})$, $[F(\alpha) : F] = \deg m_{\alpha,F}$, and $g(\alpha) = 0$ iff $m_{\alpha,F} \mid g$; α is algebraic iff $[F(\alpha) : F] < \infty$. *(proved here)* Definition 5.7, Proposition 5.8.

5.4 Algebraic extensions. Finite extensions are algebraic; $F(\alpha_1, \ldots, \alpha_r)$ with α_i algebraic

is finite of degree at most $\prod \deg m_{\alpha_i,F}$; algebraic elements form a subfield; algebraic over algebraic is algebraic. *(proved here)* Proposition 5.9.

5.5 Algebraic closure. (a) Every field has an algebraic closure, unique up to (non-unique) isomorphism. (b) An embedding $F \to \Omega$, Ω algebraically closed, extends to any algebraic L/F. (c) $\overline{\mathbb{Q}} = \{z \in \mathbb{C} : z \text{ algebraic over } \mathbb{Q}\}$ is an algebraic closure of $\mathbb{Q}$, countable. (d) Every F-embedding $\overline{\mathbb{F}} \to \overline{\mathbb{F}}$ is an automorphism, so every F-embedding $K \to \overline{\mathbb{F}}$ of a subextension $K \subseteq \overline{\mathbb{F}}$ extends to an element of $\mathrm{Aut}(\overline{\mathbb{F}}/F)$. *((a) and (b) for infinite L proof sketched here; (b) for finite L, (c) and (d) given (b) proved here)* Theorem 5.10.

5.6 Splitting fields. A splitting field of $f \in F[x]$ exists, of degree at most $n!$; an isomorphism $F \to F'$ extends to an isomorphism of splitting fields of f and $\phi(f)$, in at most $[L : F]$ ways, exactly $[L : F]$ if f is separable. *(proved here; families of polynomials sketched)* Theorem 5.12.

5.7 Normal extensions. For L/F algebraic inside $\overline{\mathbb{F}}$, equivalent: every irreducible polynomial over F with a root in L splits in L; L is a splitting field of a family; every F-embedding $L \to \overline{\mathbb{F}}$ has image L. Normal closures exist; normality is not transitive. *(proved here)* Definition 5.13, Proposition 5.14.

5.8 Separability. An irreducible f is inseparable iff $f' = 0$ iff $\mathrm{char}\, F = p > 0$ and $f \in F[x^p]$; F is perfect iff $\mathrm{char}\, F = 0$ or $F = F^p$; $[L : F]_s = \#\mathrm{Emb}_F(L, \overline{\mathbb{F}})$ divides $[L : F]$, with equality iff L/F is separable, and is multiplicative in towers. *(proved here)* Definition 5.15, Proposition 5.16.

5.9 Primitive element theorem. A finite separable extension is simple; a finite extension is simple iff it has finitely many intermediate fields. *(proved here)* Theorem 5.17.

5.10 Separable closure. F^{sep} is a field, normal and separable over F, equal to $\overline{\mathbb{F}}$ when F is perfect. *(proved here)* Proposition 5.18.

5.11 Dedekind's lemma. Distinct homomorphisms $G \to L^\times$ from a monoid are linearly independent over L. *(proved here)* Theorem 5.19.

5.12 Artin's theorem. For a finite group G of automorphisms of L, L/L^G is finite, normal and separable of degree $\#G$, and $\mathrm{Aut}(L/L^G) = G$. For any finite L/F, $\#\,\mathrm{Aut}(L/F) \le [L : F]$, with equality iff L/F is normal and separable. *(proved here)* Theorem 5.20.

5.13 Galois extensions (definition and theorem). L/F algebraic is Galois if normal and separable; for L/F finite: Galois iff splitting field of a separable polynomial iff $L^{\mathrm{Aut}(L/F)} = F$ iff $\#\,\mathrm{Aut}(L/F) = [L : F]$. *(proved here)* Definition 5.21, Theorem 5.22.

5.14 Fundamental theorem. For L/F finite Galois with group G, $H \mapsto L^H$ and $M \mapsto \mathrm{Gal}(L/M)$ are inverse inclusion-reversing bijections; $[M : F]$ is the index of $\mathrm{Gal}(L/M)$; $\mathrm{Gal}(L/\sigma M) = \sigma\,\mathrm{Gal}(L/M)\sigma^{-1}$; M/F is Galois iff $\mathrm{Gal}(L/M)$ is normal in G, and then $G/\,\mathrm{Gal}(L/M) \simeq \mathrm{Gal}(M/F)$. *(proved here)* Theorem 5.23.

5.15 Translation. For L/F Galois and any extension M/F, the extension LM/M is Galois and restriction is an isomorphism $\mathrm{Gal}(LM/M) \simeq \mathrm{Gal}(L/L\cap M)$; $\mathrm{Gal}(L_1L_2/F) \to \mathrm{Gal}(L_1/F) \times \mathrm{Gal}(L_2/F)$ is injective, bijective iff $L_1 \cap L_2 = F$. *(proved here; the infinite case in Corollary 5.57)* Proposition 5.24.

5.16 Finite fields. Inside $\overline{\mathbb{F}}_p$, $\mathbb{F}_{q^n}$ is the unique extension of $\mathbb{F}_q$ of degree n; it is Galois with cyclic group generated by Frob_q; its subfields are the $\mathbb{F}_{q^d}$, $d \mid n$; an irreducible polynomial of degree d over $\mathbb{F}_q$ has the roots α^{q^i}, $0 \le i < d$. *(proved here)* Theorem 5.25.

5.17 Cyclotomic polynomials modulo p. For $p \nmid n$ and f the order of p in $(\mathbb{Z}/n)^\times$, $\Phi_n \bmod p$ is the product of $\varphi(n)/f$ distinct irreducible polynomials of degree f, and $\mathbb{F}_p(\mu_n) = \mathbb{F}_{p^f}$. *(proved here)* Proposition 5.26.

5.18 Quadratic extensions. If $\mathrm{char}\, F \neq 2$, the quadratic extensions are the $F(\sqrt{d})$, in bijection with the nontrivial elements of $F^\times/F^{\times 2}$; two independent classes give a V_4-extension with three quadratic subfields. *(proved here)* Proposition 5.27.

5.19 Cyclotomic fields. Φ_n is irreducible over $\mathbb{Q}$; $a \mapsto \sigma_a$, $\sigma_a(\zeta) = \zeta^a$ on μ_n, is an isomorphism $(\mathbb{Z}/n)^\times \simeq \mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$; $\mathbb{Q}(\zeta_m) \cap \mathbb{Q}(\zeta_n) = \mathbb{Q}(\zeta_{\gcd(m,n)})$, $\mathbb{Q}(\zeta_m)\mathbb{Q}(\zeta_n) = \mathbb{Q}(\zeta_{\mathrm{lcm}(m,n)})$; $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$, $\mathbb{Q}(\zeta_8) = \mathbb{Q}(i, \sqrt{2})$. *(proved here)* Theorem 5.28.

5.20 $\mathbb{Q}(\sqrt{\ell^*})$. For odd ℓ, $\mathbb{Q}(\sqrt{\ell^*})$ is the unique quadratic subfield of $\mathbb{Q}(\zeta_\ell)$, $\sigma_a(\sqrt{\ell^*}) = (\frac{a}{\ell})\sqrt{\ell^*}$, so $\chi_{\ell^*} = \bar{\chi}_\ell^{(\ell-1)/2}$; $\chi_{\ell^*} = \bar{\chi}_\ell$ iff $\ell = 3$; every quadratic field lies in $\mathbb{Q}(\zeta_{|D|})$, D its discriminant. *(proved here)* Proposition 5.29.

5.21 Norm and trace (definition and proposition). $\mathrm{N}_{L/F}$, $\mathrm{Tr}_{L/F}$ are the determinant and trace of multiplication, the product and sum of the conjugates; multiplicative, additive, transitive. *(proved here)* Definition 5.32, Proposition 5.33.

5.22 Hilbert's Theorem 90. For L/F cyclic with generator σ: $\mathrm{N}(b) = 1$ iff $b = c/\sigma(c)$; $\mathrm{Tr}(b) = 0$ iff $b = c - \sigma(c)$; for L/F finite Galois every (a_σ) with $a_{\sigma\tau} = a_\sigma \sigma(a_\tau)$ is $a_\sigma = \sigma(c)/c$. *(proved here)* Theorem 5.34.

5.23 Kummer characters. If $\mathrm{char}\, F \nmid n$ and $\mu_n \subset F$, $\chi_a(\sigma) = \sigma(\alpha)/\alpha$ $(\alpha^n = a)$ is a homomorphism to μ_n independent of α, with kernel $\mathrm{Gal}(L/F(\alpha))$; $[F(\alpha) : F]$ is the order of a in $F^\times/F^{\times n}$; $\chi_a = 1$ iff $a \in F^{\times n}$; $x^n - a$ is irreducible iff $a \notin F^{\times p}$ for every prime $p \mid n$. *(proved here; Capelli's theorem stated)* Proposition 5.35.

5.24 Cyclic extensions. If $\mathrm{char}\, F \nmid n$ and $\mu_n \subset F$, every cyclic extension of degree n is $F(\alpha)$ with $\alpha^n \in F$. *(proved here)* Theorem 5.36.

5.25 Kummer theory. If $\mathrm{char}\, F \nmid n$ and $\mu_n \subset F$, $\Delta \mapsto F(\Delta^{1/n})$ is a bijection from the groups $F^{\times n} \subseteq \Delta \subseteq F^\times$ with $\Delta/F^{\times n}$ finite to the finite abelian extensions of exponent dividing n, and $\mathrm{Gal}(F(\Delta^{1/n})/F) \times \Delta/F^{\times n} \to \mu_n$ is a perfect pairing. *(proved here)* Theorem 5.37.

5.26 The affine shape. Without $\mu_n \subset F$, $\sigma \mapsto \left(\begin{smallmatrix} u(\sigma) & b(\sigma) \\ 0 & 1 \end{smallmatrix}\right)$ embeds $\mathrm{Gal}(F(\mu_n, a^{1/n})/F)$ in $\mathbb{Z}/n \rtimes (\mathbb{Z}/n)^\times$. *(proved here)* Proposition 5.38.

5.27 Kummer theory over $\mathbb{F}_q$. For $\ell \nmid q$, $v = v_\ell(q-1)$, $u \in \mathbb{F}_q^\times$, $k \le v$: $\chi_u(\mathrm{Frob}_q) = u^{(q-1)/\ell^k}$; $u \mapsto u^{(q-1)/\ell^v}$ identifies $\mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^v}$ with $\mu_{\ell^v}(\mathbb{F}_q)$; the ℓ-adic value $\kappa_u(\mathrm{Frob}_q) \in \mathbb{Z}_\ell(1)/(q-1)$ is the class of u, of valuation $\ge k$ iff $u \in (\mathbb{F}_q^\times)^{\ell^k}$. *(proved here)* Proposition 5.39.

5.28 Artin-Schreier theory. In characteristic p, $x^p - x - a$ is split or irreducible with cyclic group of order p, and every cyclic extension of degree p is of this form; $\mathrm{Hom}_{\mathrm{cont}}(G_F, \mathbb{Z}/p) \simeq F/\wp(F)$. *((a), (b) proved here; (c) proof sketched here)* Theorem 5.41.

5.29 Galois group of a polynomial. G_f acts faithfully on the roots; its orbits are the root sets of the irreducible factors, of sizes $[F(r):F]$; over an intermediate field M of a Galois Ω/F, the irreducible factors over M are the $\mathrm{Gal}(\Omega/M)$-orbits. *(proved here)* Proposition 5.42.

5.30 Discriminant (definition and proposition). For $f = a\prod_i (x - r_i)$,

$$\operatorname{disc}(f) = a^{2n-2}\prod_{i<j}(r_i - r_j)^2 = (-1)^{n(n-1)/2}a^{n-2}\prod_i f'(r_i);$$

if $\operatorname{char} F \neq 2$, $G_f \subseteq A_n$ iff $\operatorname{disc} f \in F^{\times 2}$, and $F(\sqrt{\operatorname{disc} f})$ is cut out by the sign character; $\operatorname{disc}(x^3 + px + q) = -4p^3 - 27q^2$, $\operatorname{disc}(x^n - a) = (-1)^{(n-1)(n-2)/2}n^n a^{n-1}$, $\operatorname{disc}(\Phi_\ell) = (-1)^{(\ell-1)/2}\ell^{\ell-2}$. *(proved here)* Definition 5.43, Proposition 5.44.

5.31 Cubics. An irreducible separable cubic has group A_3 or S_3 according as its discriminant is a square or not. *(proved here)* Proposition 5.45.

5.32 Quartics. The resolvent cubic $R_f = y^3 - by^2 + (ac - 4d)y - (a^2d - 4bd + c^2)$ has $\operatorname{disc} R_f = \operatorname{disc} f$; an irreducible quartic has group S_4, A_4, V_4, D_4 or C_4, read off from R_f, $\operatorname{disc} f$, and the factorisation of f over $F(\sqrt{\operatorname{disc} f})$. *(proved here)* Proposition 5.46.

5.33 Quartics and the four lines. If the roots of a separable quartic f correspond G_F-equivariantly to the four lines of $V = \mathbb{F}_3^2$ under $\rho\colon G_F \to \mathrm{GL}(V)$ with image H, then G_f is the image of H in $\mathrm{PGL}_2(\mathbb{F}_3) \simeq S_4$, the factors of f are the orbits of H on the lines, $F(\sqrt{\operatorname{disc} f})$ is cut out by $\det\rho$; the image is $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ or $N_s(\mathbb{F}_3)$ (when H fixes no line and contains an element of determinant -1 and trace 0) according as f is irreducible with group S_4, irreducible with group D_4, or a product of two irreducible quadratics. *(proved here)* Proposition 5.47.

5.34 Nonempty inverse limits. An inverse limit, over a directed set, of nonempty finite sets is nonempty. *(proved here)* Lemma 5.50.

5.35 Infinite Galois extensions. $\mathrm{Gal}(L/F) = \varprojlim \mathrm{Gal}(K/F)$ over the finite Galois $K \subseteq L$, a profinite group in the Krull topology. *(proved here)* Proposition 5.51.

5.36 Krull's fundamental theorem. Closed subgroups correspond to intermediate fields; $\mathrm{Gal}(L/L^H) = \overline{H}$; open subgroups correspond to finite subextensions, normal closed subgroups to Galois subextensions, with $G/\mathrm{Gal}(L/M) \simeq \mathrm{Gal}(M/F)$ topologically. *(proved here)* Theorem 5.52.

5.37 The absolute Galois group (definition and proposition). $G_K \subseteq G_F$ is open of index $[K:F]$ for K/F finite separable, every open subgroup is one, $G_K \trianglelefteq G_F$ iff K/F is Galois; $G_{\mathbb{F}_q} \simeq \widehat{\mathbb{Z}}$ with $1 \mapsto \mathrm{Frob}_q$; $G_{\mathbb{Q}}^{\mathrm{ab}} \simeq \widehat{\mathbb{Z}}^\times$. *(proved here, except the last statement, stated; reference)* Definition 5.53, Proposition 5.54.

5.38 Absolute Kummer theory. If $\operatorname{char} F \nmid n$ and $\mu_n \subset F$, $a \mapsto \chi_a$ is an isomorphism $F^\times/F^{\times n} \simeq \mathrm{Hom}_{\mathrm{cont}}(G_F, \mu_n)$; for $n = 2$, $\operatorname{char} F \neq 2$: $F^\times/F^{\times 2} \simeq \mathrm{Hom}_{\mathrm{cont}}(G_F, \{\pm 1\})$. *(proved here)* Corollary 5.56.

5.39 Translation, infinite case. The isomorphism $\mathrm{Gal}(LM/M) \simeq \mathrm{Gal}(L/L \cap M)$ holds for infinite L/F, as topological groups. *(proved here)* Corollary 5.57.

5.40 The cyclotomic character (definition and proposition). $\chi_\ell\colon G_{\mathbb{Q}} \to \mathbb{Z}_\ell^\times$, $\sigma(\zeta) = \zeta^{\chi_\ell(\sigma)}$ on μ_{ℓ^∞}, is continuous and surjective with kernel $G_{\mathbb{Q}(\mu_{\ell^\infty})}$; $\bar\chi_\ell$ is surjective onto $\mathbb{F}_\ell^\times$ with kernel $G_{\mathbb{Q}(\zeta_\ell)}$; over any F of characteristic $\neq \ell$, G_F acts on $\mathbb{Z}_\ell(1)$ through χ_ℓ, and $\chi_\ell(\mathrm{Frob}_q) = q$ on $G_{\mathbb{F}_q}$. *(proved here)* Definition 5.58, Proposition 5.59.

5.41 Complex conjugation. $c \in G_{\mathbb{Q}}$ has order 2, $\chi_\ell(c) = -1$, $\chi_d(c) = -1$ iff $d < 0$; if $\det\rho(c) = -1$ for $\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(k)$, $\mathrm{char}\, k \neq 2$, then $\rho(c) \sim \mathrm{diag}(1,-1)$ has trace 0 and ρ is irreducible iff absolutely irreducible. Every nontrivial element of finite order of $G_{\mathbb{Q}}$ is a complex conjugation. *(proved here, except the last statement, stated; reference)* Proposition 5.60.

5.42 Continuous representations (definition and proposition). Over a discrete field, continuous means open kernel, and the field cut out is finite Galois with group the image; over $\mathcal{O}$, continuous means continuous modulo every ϖ^m; every continuous representation over a finite extension E_λ of $\mathbb{Q}_\ell$ preserves a lattice; continuous complex representations of profinite groups have finite image. *(proved here)* Definition 5.61, Proposition 5.62.

5.43 Quadratic characters of $G_{\mathbb{Q}}$. $d \mapsto \chi_d$ is an isomorphism $\mathbb{Q}^\times/\mathbb{Q}^{\times 2} \simeq \mathrm{Hom}_{\mathrm{cont}}(G_{\mathbb{Q}}, \{\pm 1\})$, $\ker\chi_d = G_{\mathbb{Q}(\sqrt{d})}$, $\chi_{dd'} = \chi_d\chi_{d'}$; for $p \nmid D$, $\chi_d(\mathrm{Frob}_p) = \left(\frac{D}{p}\right)$ and $\chi_{\ell^*}(\mathrm{Frob}_p) = \left(\frac{p}{\ell}\right)$. *((a), (b) proved here; (c), (d) stated; reference)* Proposition 5.63.

5.44 Twists. $\det(\rho\otimes\chi) = \chi^n \det\rho$; if $\rho \simeq \rho\otimes\chi$ in dimension 2 then $\chi^2 = 1$; for $\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{Z}_\ell)$, ℓ odd, $\rho \bmod \ell^k \simeq (\rho \otimes \chi_\ell) \bmod \ell^k$ with $k \geq 1$ forces $\ell = 3$, $k = 1$. *(proved here)* Proposition 5.64.

5.45 Restriction to open subgroups. $\rho(G_K)$ has index at most $[K:F]$ in $\rho(G_F)$; if K is cut out by $\delta \circ \rho$ then $\rho(G_K) = \rho(G_F) \cap \ker\delta$; for $E/\mathbb{Q}$, $\bar\rho_{E,\ell}(G_{\mathbb{Q}(\sqrt{\ell^*})})$ is the set of elements of the image with square determinant, the determinant-one subgroup when $\ell = 3$. *(proved here)* Proposition 5.66.

5.46 Index two. For $H \subseteq G$ open of index 2 with character χ and ρ two-dimensional, absolutely irreducible, $\mathrm{char}\, k \neq 2$: $\rho|_H$ is not absolutely irreducible iff $\rho \simeq \rho \otimes \chi$ iff $\rho \otimes \bar k \simeq \mathrm{Ind}_H^G \psi$ for a continuous character ψ of H. *(proved here)* Proposition 5.67.

5.47 Reduction. Reductions of two stable lattices have isomorphic semisimplifications; if one is irreducible the lattices are homothetic. *(proved here)* Proposition 5.69.

5.48 The ℓ-adic Kummer cocycle. For $a \in F^\times$ and $\ell \neq \mathrm{char}\, F$, $\kappa_a(\sigma) = (\sigma(\alpha_k)/\alpha_k)_k \in \mathbb{Z}_\ell(1)$ satisfies $\kappa_a(\sigma\tau) = \kappa_a(\sigma) + \chi_\ell(\sigma)\kappa_a(\tau)$, so, writing $\kappa_a = b \cdot e$ for a generator e of $\mathbb{Z}_\ell(1)$, $\sigma \mapsto \left(\begin{smallmatrix} \chi_\ell(\sigma) & b(\sigma) \\ 0 & 1 \end{smallmatrix}\right)$ is a continuous representation; it changes by a coboundary with the root system; $\kappa_a(\sigma\tau\sigma^{-1}) = \chi_\ell(\sigma)\kappa_a(\tau)$ for $\tau \in \ker\chi_\ell$; if $\mu_{\ell^k} \subset K$, $\kappa_a \bmod \ell^k$ vanishes on G_K iff $a \in K^{\times \ell^k}$. *(proved here)* Proposition 5.70.

5.49 Frobenius elements. For $K/\mathbb{Q}$ finite Galois unramified at p, the Frobenius elements at the primes above p form a conjugacy class Frob_p, trivial iff p splits completely, compatible with quotients; $\mathrm{Frob}_p = \sigma_p$ in $\mathbb{Q}(\zeta_n)$; Frob_p acts on the roots of f with the cycle type of the factorisation of $f \bmod p$ (Dedekind). *(stated; reference)* Theorem 5.72.

5.50 Density (definition). Dirichlet and natural density; density one; almost all. Definition 5.74.

5.51 Chebotarev's density theorem. For $K/\mathbb{Q}$ finite Galois with group G and a conjugacy class C, the primes with $\mathrm{Frob}_p = C$ have density $\#C/\#G$. *(stated; reference)* Theorem 5.75.

5.52 Density of Frobenius elements. For $L/\mathbb{Q}$ Galois unramified outside a finite S and X of density one, the Frobenius elements at primes over $X \setminus S$ are dense in $\mathrm{Gal}(L/\mathbb{Q})$. *(proved here, from Chebotarev)* Corollary 5.76.

5.53 Chebotarev and Brauer-Nesbitt. Two continuous semisimple n-dimensional representations of $G_{\mathbb{Q}}$, unramified outside a finite set, with the same Frobenius characteristic polynomials on a set of density one, are isomorphic. *(proved here)* Corollary 5.77.

5.54 Congruent traces. If $\rho_1, \rho_2 \colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathcal{O})$ have congruent traces and determinants of Frobenius modulo λ on a set of density one, then $\bar\rho_1^{ss} \simeq \bar\rho_2^{ss}$, and $\bar\rho_2 \simeq \bar\rho_1$ if $\bar\rho_1$ is absolutely irreducible; (d) for a newform h of weight 2 on $\Gamma_0(M)$ and ℓ odd, $a_p(h) \equiv a_p(E) \pmod\lambda$ on a set of density one gives $\bar\rho_h \simeq \bar\rho_{E,\ell} \otimes k$ when $\bar\rho_{E,\ell}$ is irreducible. *((a) to (c) proved here; the newform statement (d) proved here, given the representations of newforms of Chapter 15)* Corollary 5.78.

5.1 Field extensions and algebraic elements

This section fixes the conventions of the chapter and introduces the basic objects: field extensions, their degree, algebraic elements and their minimal polynomials, and the algebraic closures $\overline{\mathbb{F}}$ and $\overline{\mathbb{Q}}$. Everything in the paper takes place inside $\overline{\mathbb{Q}}$ or inside an algebraic closure of $\mathbb{Q}_q$ or $\mathbb{F}_q$: the Galois group $G_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ of Section 1.1 of the paper, the fields $\mathbb{Q}(\sqrt{\ell^*})$ and $\mathbb{Q}(\sqrt{-3})$ of Theorem thm:main and Proposition prop:ns, and the unramified extension $\mathbb{Q}_q^{\mathrm{ur}}$ of Lemma lem:tamagawa-exp. Fields, rings, ideals, polynomial rings, Gauss's lemma, Kronecker's construction $F[x]/(f)$ and finite fields are Chapter 2.

Convention 5.1 (Fields, closures, composition)**.** $\overline{\mathbb{Q}} \subset \mathbb{C}$ is the field of complex numbers algebraic over $\mathbb{Q}$ (Theorem 5.10); every algebraic extension of $\mathbb{Q}$ is taken inside $\overline{\mathbb{Q}}$, $G_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ and $G_K = \mathrm{Gal}(\overline{\mathbb{Q}}/K) \subseteq G_{\mathbb{Q}}$ for $K \subseteq \overline{\mathbb{Q}}$. For a general field F we fix an algebraic closure $\overline{\mathbb{F}}$ and the separable closure $F^{\mathrm{sep}} \subseteq \overline{\mathbb{F}}$, and put $G_F = \mathrm{Gal}(F^{\mathrm{sep}}/F)$ (Definition 5.53). Automorphisms are composed as maps, $(\sigma\tau)(x) = \sigma(\tau(x))$, and groups act on the left. As in the rest of the book (Appendix B, convention B-C1), p, q, ℓ are primes, except that in statements about finite fields q is a power of a prime p; in the paper's applications q is a bad prime of E and $\mathbb{F}_q$ its residue field, and the two meanings never occur in one display.

Convention 5.2 (Frobenius is arithmetic)**.** For a finite field $\mathbb{F}_q$, $\mathrm{Frob}_q \in \mathrm{Gal}(\overline{\mathbb{F}}_q/\mathbb{F}_q)$ is $x \mapsto x^q$. A Frobenius element Frob_p at a prime p (Theorem 5.72, made precise in Chapter 6) is *arithmetic*: it induces $x \mapsto x^p$ on residue fields, so it acts on μ_n $(p \nmid n)$ by $\zeta \mapsto \zeta^p$ and $\chi_\ell(\mathrm{Frob}_p) = p$ for $\ell \neq p$. This is the convention of the proof of Lemma lem:tamfactor; the geometric Frobenius Frob_p^{-1} enters only through L-factors, in later chapters.

Convention 5.3 (Characters)**.** (a) For $d \in \mathbb{Q}^\times$ not a square, $\chi_d\colon G_{\mathbb{Q}} \to \{\pm 1\}$ is $\sigma \mapsto \sigma(\sqrt{d})/\sqrt{d}$. It depends only on the class of d modulo squares, and its kernel is $G_{\mathbb{Q}(\sqrt{d})}$. For an odd prime q, $q^* = (-1)^{(q-1)/2}q$ and χ_{q^*} is the quadratic character of conductor q, the character of $\mathbb{Q}(\sqrt{q^*})$; the book never writes χ_q for it, and neither does the paper. χ_{-3} and χ_{-4} are the characters of $\mathbb{Q}(\sqrt{-3})$ and $\mathbb{Q}(i)$. A numerical subscript always means such a quadratic character, written with the sign of d.

(b) $\chi_\ell\colon G_{\mathbb{Q}} \to \mathbb{Z}_\ell^\times$ is the ℓ-adic cyclotomic character, $\sigma(\zeta) = \zeta^{\chi_\ell(\sigma)}$ on μ_{ℓ^∞} (Definition 5.58); $\bar{\chi}_\ell\colon G_{\mathbb{Q}} \to \mathbb{F}_\ell^\times$ is its reduction. A prime-letter subscript (χ_ℓ, χ_p) always means the cyclotomic character; at the number 3 it is written χ_3^{cyc}, and its reduction $\bar{\chi}_3$. We shall prove $\chi_{\ell^*} = \bar{\chi}_\ell^{(\ell-1)/2}$, which equals $\bar{\chi}_\ell$ only for $\ell = 3$ (Proposition 5.29).

(c) A Kummer character χ_a (Proposition 5.35) takes values in the group μ_n of roots of unity, not in $\mathbb{Z}/n$; the two are identified only after a primitive n-th root of unity is chosen. $\mathbb{Z}_\ell(1) = \varprojlim_k \mu_{\ell^k}$, with transition maps $\zeta \mapsto \zeta^\ell$, is written multiplicatively as a set of compatible systems $(\zeta_k)_k$ and additively when it receives cocycles: $(\zeta_k) + (\zeta_k') = (\zeta_k\zeta_k')$ and $a \cdot (\zeta_k) = (\zeta_k^a)$ for $a \in \mathbb{Z}_\ell$ (with ζ_k^a meaning $\zeta_k^{a \bmod \ell^k}$).

Convention 5.4 (Representations)**.** A representation of a profinite group G is a continuous homomorphism $\rho\colon G \to \mathrm{GL}_n(k)$ (Definition 5.61), where k is a finite field or $\overline{\mathbb{F}}_\ell$ with the discrete

topology, or a finite extension E_λ of $\mathbb{Q}_\ell$ with its ℓ-adic topology, or the ring of integers $\mathcal{O}$ of such an E_λ. For $\rho\colon G \to \mathrm{GL}_n(\mathcal{O})$, $\rho \bmod \varpi^m$ is the action on $\mathcal{O}^n/\varpi^m\mathcal{O}^n$ and $\bar\rho = \rho \bmod \varpi$. Irreducibility, absolute irreducibility, ρ^{ss}, $\rho\otimes\chi$, Ind and Res are as in Chapter 4. "ρ is absolutely irreducible on G_K" means that $(\rho\otimes\bar k)|_{G_K}$ is irreducible.

Definition 5.5 (Field extensions)**.** A *field extension* L/F is a field L together with a subfield F. Then L is an F-vector space, and its dimension $[L:F] = \dim_F L \in \{1,2,3,\dots\}\cup\{\infty\}$ is the *degree* of L/F; the extension is *finite* if $[L:F]<\infty$. A field M with $F\subseteq M\subseteq L$ is an *intermediate field*. For $S\subseteq L$, $F(S)$ is the smallest subfield of L containing F and S, and $F[S]$ the smallest subring; $F(\alpha_1,\dots,\alpha_r)$ and $F[\alpha_1,\dots,\alpha_r]$ are the usual abbreviations. For two subfields L_1, L_2 of a field, the *compositum* L_1L_2 is the smallest subfield containing both. An *F-embedding* of L into a field $\Omega\supseteq F$ is a ring homomorphism $L\to\Omega$ that is the identity on F (it is automatically injective, L being a field); $\mathrm{Emb}_F(L,\Omega)$ is the set of them, and $\mathrm{Aut}(L/F)$ the group of F-automorphisms of L.

The degree is the first invariant of an extension, and it needs nothing beyond a first course in linear algebra: L is simply a vector space over F. For example $[\mathbb{C}:\mathbb{R}]=2$, with basis $1, i$. Next, $[\mathbb{Q}(\sqrt2):\mathbb{Q}]=2$, with basis $1,\sqrt2$: the numbers $x+y\sqrt2$ $(x,y\in\mathbb{Q})$ form a ring, and a field because $(x+y\sqrt2)^{-1} = (x-y\sqrt2)/(x^2-2y^2)$ for $(x,y)\neq(0,0)$ (the denominator is nonzero as $\sqrt2\notin\mathbb{Q}$); and $1,\sqrt2$ are independent over $\mathbb{Q}$, again because $\sqrt2\notin\mathbb{Q}$. Finally $[\mathbb{R}:\mathbb{Q}]=\infty$, since a $\mathbb{Q}$-vector space of finite dimension d is in bijection with $\mathbb{Q}^d$, hence countable, while $\mathbb{R}$ is not. The tower law below turns statements about degrees into divisibility statements, and most impossibility arguments of the chapter are of that kind.

Proposition 5.6 (Tower law)**.** *Let $F\subseteq L\subseteq M$ be fields. If $(x_i)_{i\in I}$ is an F-basis of L and $(y_j)_{j\in J}$ an L-basis of M, then $(x_iy_j)_{(i,j)\in I\times J}$ is an F-basis of M. Hence $[M:F]=[M:L]\,[L:F]$, with the convention $\infty\cdot n = n\cdot\infty=\infty$; in particular M/F is finite iff M/L and L/F are, and then $[L:F]$ and $[M:L]$ divide $[M:F]$.*

Proof. Spanning: an element $z\in M$ is $z=\sum_j b_jy_j$ with $b_j\in L$ (finitely many nonzero), and each $b_j=\sum_i a_{ij}x_i$ with $a_{ij}\in F$; so $z=\sum_{i,j}a_{ij}x_iy_j$. Independence: if $\sum_{i,j}a_{ij}x_iy_j=0$ with $a_{ij}\in F$, almost all zero, then $\sum_j(\sum_i a_{ij}x_i)y_j=0$ with coefficients in L, so $\sum_i a_{ij}x_i=0$ for every j, and then $a_{ij}=0$ for all i,j. The degree formula is the count of $I\times J$. □

A typical use: $\sqrt2\notin\mathbb{Q}(2^{1/3})$. Indeed $[\mathbb{Q}(\sqrt2):\mathbb{Q}]=2$ and $[\mathbb{Q}(2^{1/3}):\mathbb{Q}]=3$ (the minimal polynomials are x^2-2 and x^3-2, Proposition 5.8 below), and if $\mathbb{Q}(\sqrt2)\subseteq\mathbb{Q}(2^{1/3})$ the tower law would make 2 divide 3. In the same way $[\mathbb{Q}(\sqrt2,2^{1/3}):\mathbb{Q}]=6$: it is divisible by 2 and by 3, and it is at most $2\cdot3$, because $2^{1/3}$ is a root of x^3-2 over $\mathbb{Q}(\sqrt2)$, so $[\mathbb{Q}(\sqrt2,2^{1/3}):\mathbb{Q}(\sqrt2)]\le3$ (Proposition 5.8(ii), (iv)).

Definition 5.7 (Algebraic elements)**.** Let L/F be an extension. An element $\alpha\in L$ is *algebraic* over F if $g(\alpha)=0$ for some nonzero $g\in F[x]$, and *transcendental* otherwise. The extension L/F is *algebraic* if every element of L is algebraic over F.

Proposition 5.8 (Minimal polynomial)**.** *Let L/F be an extension and $\alpha\in L$ algebraic over F.*

(i) The kernel of the evaluation map $F[x]\to L$, $g\mapsto g(\alpha)$, is generated by a unique monic irreducible polynomial $m_{\alpha,F}$, the minimal polynomial *of α over F. For $g\in F[x]$, $g(\alpha)=0$ iff $m_{\alpha,F}\mid g$; and $m_{\alpha,F}$ is the unique monic irreducible polynomial in $F[x]$ with root α.*

(ii) $F[\alpha] = F(\alpha) \simeq F[x]/(m_{\alpha,F})$, *and* $1, \alpha, \dots, \alpha^{d-1}$ *is an* F*-basis of* $F(\alpha)$, *where* $d = \deg m_{\alpha,F}$; *so* $[F(\alpha) : F] = \deg m_{\alpha,F}$.

(iii) Conversely, if $\beta \in L$ *and* $[F(\beta) : F] < \infty$, *then* β *is algebraic over* F.

(iv) If $F \subseteq M \subseteq L$, *then* $m_{\alpha,M}$ *divides* $m_{\alpha,F}$ *in* $M[x]$.

Proof. (i) The kernel $\mathfrak{p}$ is an ideal of the principal ideal domain $F[x]$ (Chapter 2); it is nonzero as α is algebraic, and prime because $F[x]/\mathfrak{p}$ embeds in the field L. A nonzero prime ideal of $F[x]$ is generated by an irreducible polynomial, unique up to a unit, hence unique when monic. If h is monic irreducible with $h(\alpha) = 0$, then $m_{\alpha,F} \mid h$, and irreducibility forces $h = m_{\alpha,F}$. (ii) The image of evaluation is $F[\alpha]$, so $F[\alpha] \simeq F[x]/(m_{\alpha,F})$, which is a field because $(m_{\alpha,F})$ is maximal (Kronecker's construction, Chapter 2). For the basis: by division with remainder every $g \in F[x]$ is $g = s\, m_{\alpha,F} + r$ with $\deg r < d$, so $g(\alpha) = r(\alpha)$ is an F-linear combination of $1, \alpha, \dots, \alpha^{d-1}$; and a relation $\sum_{i<d} c_i \alpha^i = 0$ is a polynomial of degree $< d$ vanishing at α, hence divisible by $m_{\alpha,F}$ by (i), hence zero. A subring of L containing F and α that is a field contains $F(\alpha)$; so $F[\alpha] = F(\alpha)$. (iii) If $[F(\beta) : F] = n < \infty$, the $n+1$ elements $1, \beta, \dots, \beta^n$ are linearly dependent over F, which is a nonzero polynomial relation. (iv) $m_{\alpha,F} \in M[x]$ has the root α; apply (i) over M. □

For example $m_{\sqrt{2},\mathbb{Q}} = x^2 - 2$, $m_{2^{1/3},\mathbb{Q}} = x^3 - 2$ (Eisenstein, Chapter 2), and $m_{\zeta_n,\mathbb{Q}} = \Phi_n$ (Theorem 5.28). The number π is transcendental over $\mathbb{Q}$ (Lindemann's theorem; we do not prove this, see [135, Chapter 1] for references); the book never uses transcendental elements except through the countability argument of Theorem 5.10(c).

Proposition 5.9 (Algebraic extensions)**.** *Let* L/F *be an extension.*

(a) If L/F *is finite, it is algebraic.*

(b) If $\alpha_1, \dots, \alpha_r \in L$ *are algebraic over* F, *then* $F(\alpha_1, \dots, \alpha_r) = F[\alpha_1, \dots, \alpha_r]$ *is finite over* F, *of degree at most* $\prod_i \deg m_{\alpha_i,F}$.

(c) The elements of L *algebraic over* F *form a subfield of* L.

(d) If M/L *and* L/F *are algebraic, then* M/F *is algebraic.*

(e) A finite extension is generated by finitely many algebraic elements.

Proof. (a) For $\alpha \in L$, $F(\alpha) \subseteq L$ has finite degree; apply Proposition 5.8(iii). (b) Induction on r. Put $F_i = F(\alpha_1, \dots, \alpha_i)$. The element α_{i+1} is a root of $m_{\alpha_{i+1},F} \in F_i[x]$, so it is algebraic over F_i and $[F_{i+1} : F_i] = \deg m_{\alpha_{i+1},F_i} \le \deg m_{\alpha_{i+1},F}$ by Proposition 5.8(ii), (iv); also $F_{i+1} = F_i[\alpha_{i+1}]$. The tower law gives the bound, and by induction $F_r = F[\alpha_1, \dots, \alpha_r]$. (c) If α, β are algebraic, $F(\alpha, \beta)$ is finite by (b), so $\alpha \pm \beta$, $\alpha\beta$ and α/β ($\beta \neq 0$), which lie in it, are algebraic by (a). (d) Let $\gamma \in M$, with $m_{\gamma,L} = x^m + c_{m-1}x^{m-1} + \cdots + c_0$. The c_i are algebraic over F, so $F' = F(c_0, \dots, c_{m-1})$ is finite over F by (b), and γ is algebraic over F', so $F'(\gamma)$ is finite over F'. By the tower law $F(\gamma) \subseteq F'(\gamma)$ is finite over F, and γ is algebraic. (e) An F-basis of L generates L, and its elements are algebraic by (a). □

Theorem 5.10 (Algebraic closure)**.** *A field* Ω *is* algebraically closed *if every nonconstant polynomial in* $\Omega[x]$ *has a root in* Ω *(equivalently, splits into linear factors). An* algebraic closure *of* F *is an algebraic extension of* F *that is algebraically closed.*

(a) Every field F has an algebraic closure $\overline{\mathbb{F}}$, and any two are F-isomorphic (by an isomorphism that is in general not unique).

(b) Let L/F be algebraic, Ω algebraically closed and $\sigma\colon F \to \Omega$ a field embedding. Then σ extends to an embedding $L \to \Omega$. If $L = F(\alpha)$, the extensions correspond bijectively to the distinct roots of $\sigma(m_{\alpha,F})$ in Ω, through $\tau \mapsto \tau(\alpha)$.

(c) $\overline{\mathbb{Q}} = \{z \in \mathbb{C} : z$ is algebraic over $\mathbb{Q}\}$ is an algebraic closure of $\mathbb{Q}$. It is countable; hence $\mathbb{C}$ is not algebraic over $\mathbb{Q}$.

(d) Every F-embedding $\overline{\mathbb{F}} \to \overline{\mathbb{F}}$ is an automorphism. Hence, for every subextension K/F of $\overline{\mathbb{F}}/F$, every F-embedding $K \to \overline{\mathbb{F}}$ extends to an element of $\mathrm{Aut}(\overline{\mathbb{F}}/F)$.

Proof of (b) for finite L, and of (c). (b), $L = F(\alpha)$. If τ extends σ, then $0 = \tau(m_{\alpha,F}(\alpha)) = \sigma(m_{\alpha,F})(\tau(\alpha))$, so $\tau(\alpha)$ is a root of $\sigma(m_{\alpha,F})$, and τ is determined by $\tau(\alpha)$ because $L = F[\alpha]$. Conversely, let $\beta \in \Omega$ be a root of $\sigma(m_{\alpha,F})$ (one exists as Ω is algebraically closed). The homomorphism $F[x] \to \Omega$, $\sum a_i x^i \mapsto \sum \sigma(a_i)\beta^i$, kills $m_{\alpha,F}$, so it factors through $F[x]/(m_{\alpha,F}) \simeq F(\alpha)$ and gives τ with $\tau(\alpha) = \beta$. For a finite L, write $L = F(\alpha_1, \dots, \alpha_r)$ (Proposition 5.9(e)) and extend step by step through $F(\alpha_1, \dots, \alpha_i)$.

(c) $\overline{\mathbb{Q}}$ is a subfield of $\mathbb{C}$ by Proposition 5.9(c), algebraic over $\mathbb{Q}$ by definition. Let $g \in \overline{\mathbb{Q}}[x]$ be nonconstant. By the fundamental theorem of algebra g has a root $z \in \mathbb{C}$. The coefficients of g generate a finite extension F' of $\mathbb{Q}$, and z is algebraic over F', so $F'(z)/\mathbb{Q}$ is finite (tower law) and z is algebraic over $\mathbb{Q}$: $z \in \overline{\mathbb{Q}}$. Countability: $\mathbb{Q}[x]$ is countable and each nonzero polynomial has finitely many roots in $\mathbb{C}$; as $\mathbb{C}$ is uncountable, some complex number is transcendental. □

Sketch of proof of (a), and of (b) for infinite L. For (b) one applies Zorn's lemma to the set of pairs (M, τ) with $F \subseteq M \subseteq L$ and $\tau\colon M \to \Omega$ extending σ, ordered by extension: a maximal pair has $M = L$, since otherwise the case $M(\alpha)$ above extends it. For (a), one constructs an algebraically closed field containing F (Artin's construction: adjoin a root of every polynomial at once, in the quotient of a large polynomial ring by a maximal ideal, and repeat countably many times, or once with an extra argument), and takes the algebraic elements in it; uniqueness follows from (b), an F-embedding $\overline{\mathbb{F}} \to \overline{\mathbb{F}}'$ having algebraically closed image over which $\overline{\mathbb{F}}'$ is algebraic, hence being surjective. We do not give the details; see [109, Chapter V, Section 2] or [58, Section 13.4]. □

Proof of (d), given (b). Let $\sigma\colon \overline{\mathbb{F}} \to \overline{\mathbb{F}}$ be an F-embedding and $x \in \overline{\mathbb{F}}$. The set R of roots of $m_{x,F}$ in $\overline{\mathbb{F}}$ is finite, and σ maps R injectively into R (as $\sigma(m_{x,F}) = m_{x,F}$); so $\sigma(R) = R$ and $x \in \sigma(\overline{\mathbb{F}})$. Thus σ is surjective. If $K \subseteq \overline{\mathbb{F}}$ and $\tau\colon K \to \overline{\mathbb{F}}$ is an F-embedding, then $\overline{\mathbb{F}}/K$ is algebraic, so by (b) τ extends to an embedding $\overline{\mathbb{F}} \to \overline{\mathbb{F}}$, which is an automorphism by what we have shown. □

Remark 5.11. The non-uniqueness in (a) is the whole subject of this chapter: for perfect F the F-automorphisms of $\overline{\mathbb{F}}$ are the elements of the absolute Galois group G_F (Definition 5.53). For $F = \mathbb{Q}$ we avoid all choices by working inside $\mathbb{C}$; the price is that one embedding $\overline{\mathbb{Q}} \subset \mathbb{C}$ is singled out, and with it one element of $G_{\mathbb{Q}}$, complex conjugation (Proposition 5.60).

5.2 Splitting fields, normality, separability

A Galois extension is one that is normal (closed under conjugation) and separable (no repeated roots). This section develops the two notions and the tools used everywhere afterwards: the

extension of isomorphisms to splitting fields, the separable degree, and the primitive element theorem. In the paper, every field "cut out" by a character or a representation (the proof of Proposition prop:ns: "$\det \bar\rho_{E,3} = \chi_{-3}$ cuts out $\mathbb{Q}(\sqrt{-3})$") is a normal extension of $\mathbb{Q}$; the warning examples $\mathbb{Q}(2^{1/3})$ and $\mathbb{Q}(2^{1/4})$ below show that an extension generated by one root need not be.

Theorem 5.12 (Splitting fields)**.** *Let $f \in F[x]$ have degree $n \geq 1$. A* splitting field *of f over F is an extension $L = F(r_1, \dots, r_n)$ such that $f = c\prod_{i=1}^{n}(x - r_i)$ in $L[x]$, $c \in F^\times$.*

(a) A splitting field exists, and $[L : F] \leq n!$.

(b) Let $\phi\colon F \to F'$ be an isomorphism of fields, L a splitting field of f over F and L' a splitting field of $\phi(f)$ over F'. Then ϕ extends to an isomorphism $L \to L'$. The number of extensions is at most $[L : F]$, and equal to $[L : F]$ if f has n distinct roots in L.

(c) Any two splitting fields of f over F are F-isomorphic; inside a fixed $\overline{\mathbb{F}}$ the splitting field $F(\{r \in \overline{\mathbb{F}} : f(r) = 0\})$ is unique.

The same holds for a family $\mathcal{S} \subseteq F[x]$ of nonconstant polynomials: a splitting field is an extension generated by roots of the members of $\mathcal{S}$ over which each of them splits; inside $\overline{\mathbb{F}}$ it is unique.

Proof. (a) Induction on n, the case $n = 1$ being $L = F$. By Kronecker's construction (Chapter 2) there is an extension $F(r_1)$ in which f has a root r_1, with $[F(r_1) : F] \leq n$ (the degree of the minimal polynomial of r_1, a factor of f). Then $f = (x - r_1)g$ with $g \in F(r_1)[x]$ of degree $n - 1$, and a splitting field L of g over $F(r_1)$, of degree at most $(n - 1)!$, is one of f over F. The tower law gives $[L : F] \leq n \cdot (n - 1)!$.

(b) Induction on $[L : F]$. If $[L : F] = 1$, f splits over F, so $\phi(f)$ splits over F', $L' = F'$, and ϕ is the only extension. Otherwise some root $r \in L$ of f is not in F; let $g = m_{r,F}$, of degree $d > 1$, a factor of f. Then $\phi(g)$ is an irreducible factor of $\phi(f)$, so it splits in L'; let $r'_1, \dots, r'_e$ be its distinct roots in L', with $e \leq d$, and $e = d$ if f (hence g) has distinct roots. Exactly as in the proof of Theorem 5.10(b), ϕ has exactly e extensions $\phi_j\colon F(r) \to L'$, given by $r \mapsto r'_j$, and each is an isomorphism onto $F'(r'_j)$. Now L is a splitting field of f over $F(r)$, L' one of $\phi(f) = \phi_j(f)$ over $F'(r'_j)$, and $[L : F(r)] = [L : F]/d < [L : F]$. By induction each ϕ_j extends to an isomorphism $L \to L'$, in at most $[L : F(r)]$ ways, exactly $[L : F(r)]$ if the roots are distinct. Every extension of ϕ to L sends r to some r'_j, so it is one of these. The total number is at most $e[L : F(r)] \leq d[L : F(r)] = [L : F]$, with equality in the separable case. (That an extension $\tau\colon L \to L'$ is surjective: $\tau(f) = \phi(f) = \phi(c)\prod(x - \tau(r_i))$, so the $\tau(r_i)$ are all the roots of $\phi(f)$ in L', and they generate L'.)

(c) The first statement is (b) with $\phi = \mathrm{id}$. Inside $\overline{\mathbb{F}}$, f splits and any splitting field contained in $\overline{\mathbb{F}}$ is generated by all the roots of f in $\overline{\mathbb{F}}$.

For a family, the splitting field inside $\overline{\mathbb{F}}$ is the subfield generated by all roots in $\overline{\mathbb{F}}$ of all members of $\mathcal{S}$; existence and uniqueness up to F-isomorphism of abstract ones follow from Theorem 5.10 (embed into $\overline{\mathbb{F}}$). For finite families, take the product polynomial. □

The bound in (a) improves to $[L : F] \mid n!$ (Exercise 5.85).

Definition 5.13 (Normal extensions)**.** An algebraic extension L/F with $L \subseteq \overline{\mathbb{F}}$ is *normal* if it satisfies the equivalent conditions of Proposition 5.14. For L/F finite, a *normal closure* of L is a smallest normal extension of F inside $\overline{\mathbb{F}}$ containing L.

Proposition 5.14 (Normality)**.** *For an algebraic extension $F \subseteq L \subseteq \overline{\mathbb{F}}$ the following are equivalent:*

(i) every irreducible polynomial in $F[x]$ with a root in L splits into linear factors in $L[x]$;

(ii) L is the splitting field over F of a family of polynomials;

(iii) every F-embedding $\tau\colon L \to \overline{\mathbb{F}}$ satisfies $\tau(L) = L$; that is, $\mathrm{Emb}_F(L, \overline{\mathbb{F}}) = \mathrm{Aut}(L/F)$.

Moreover: if L/F is normal and $F \subseteq M \subseteq L$, then L/M is normal. A finite $L = F(\alpha_1, \dots, \alpha_r)$ has a unique normal closure inside $\overline{\mathbb{F}}$, the splitting field of $\prod_i m_{\alpha_i,F}$, finite over F. Every extension of degree 2 is normal, but normality is not transitive: $\mathbb{Q} \subset \mathbb{Q}(\sqrt{2}) \subset \mathbb{Q}(2^{1/4})$, and $\mathbb{Q}(2^{1/3})/\mathbb{Q}$ is not normal.

Proof. (i)⇒(ii): L is the splitting field of the family $\{m_{\alpha,F} : \alpha \in L\}$, each member splitting in L by (i). (ii)⇒(iii): let L be the splitting field of $\mathcal{S}$, so L is generated by the set R of roots in $\overline{\mathbb{F}}$ of the members of $\mathcal{S}$, and $R \subseteq L$. An F-embedding τ maps a root of $g \in \mathcal{S}$ to a root of g, so $\tau(R_g) \subseteq R_g$ for the finite set R_g of roots of g, with equality because τ is injective. Hence $\tau(L)$ is generated by $\tau(R) = R$, and $\tau(L) = L$. (iii)⇒(i): let $g \in F[x]$ be irreducible with a root $\alpha \in L$, and $\beta \in \overline{\mathbb{F}}$ another root. By Theorem 5.10(b) there is an F-embedding $F(\alpha) \to \overline{\mathbb{F}}$ with $\alpha \mapsto \beta$, and it extends to an F-embedding $\tau\colon L \to \overline{\mathbb{F}}$. By (iii) $\tau(L) = L$, so $\beta \in L$; all roots of g lie in L.

If L/F is normal and $F \subseteq M \subseteq L$, every M-embedding $L \to \overline{\mathbb{F}}$ is an F-embedding, so (iii) holds for L/M. For the normal closure: the splitting field N of $\prod_i m_{\alpha_i,F}$ in $\overline{\mathbb{F}}$ is normal by (ii), finite by Theorem 5.12(a), and contains L; a normal extension of F containing L contains all roots of each $m_{\alpha_i,F}$ by (i), hence contains N.

Let $[L : F] = 2$ and let $g \in F[x]$ be irreducible with a root $\alpha \in L$. If $\alpha \in F$, g is linear. Otherwise $L = F(\alpha)$ and g is (up to a constant) $m_{\alpha,F} = x^2 + bx + c$, whose second root $-b - \alpha$ lies in L; so (i) holds. Thus $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$ and $\mathbb{Q}(2^{1/4})/\mathbb{Q}(\sqrt{2})$ are normal ($2^{1/4}$ has minimal polynomial $x^2 - \sqrt{2}$ over $\mathbb{Q}(\sqrt{2})$, as $[\mathbb{Q}(2^{1/4}) : \mathbb{Q}] = 4$ by Eisenstein). But $x^4 - 2$ is irreducible over $\mathbb{Q}$ with the root $2^{1/4} \in \mathbb{Q}(2^{1/4}) \subset \mathbb{R}$ and the non-real root $i2^{1/4}$, so $\mathbb{Q}(2^{1/4})/\mathbb{Q}$ is not normal; likewise $x^3 - 2$ has one real root and two non-real ones. □

Definition 5.15 (Separability)**.** A polynomial $f \in F[x]$ is *separable* if it has no repeated root in $\overline{\mathbb{F}}$. An algebraic element is *separable* over F if its minimal polynomial is; an algebraic extension is separable if all its elements are. F is *perfect* if every irreducible polynomial over F is separable. For L/F finite, the *separable degree* is $[L : F]_s = \#\mathrm{Emb}_F(L, \overline{\mathbb{F}})$. The *separable closure* of F in $\overline{\mathbb{F}}$ is $F^{\mathrm{sep}} = \{\alpha \in \overline{\mathbb{F}} : \alpha \text{ is separable over } F\}$.

The formal derivative f' satisfies the usual rules (Chapter 2). Since the Euclidean algorithm computes $\gcd(f, f')$ inside $F[x]$, the gcd is the same whether computed over F or over $\overline{\mathbb{F}}$; and $r \in \overline{\mathbb{F}}$ is a repeated root of f iff $f(r) = f'(r) = 0$ (write $f = (x - r)h$, so $f' = h + (x - r)h'$). Hence *f is separable iff* $\gcd(f, f') = 1$.

Proposition 5.16 (Separability)**.** *(a) An irreducible $f \in F[x]$ is inseparable iff $f' = 0$, iff* $\mathrm{char}\, F = p > 0$ *and $f \in F[x^p]$. If* $\mathrm{char}\, F = p$*, every irreducible f can be written $f(x) = g(x^{p^e})$ with $e \geq 0$ and g irreducible and separable; then f has exactly* $\deg g$ *distinct roots, each of multiplicity p^e.*

(b) F is perfect iff $\mathrm{char}\, F = 0$*, or* $\mathrm{char}\, F = p$ *and $F = F^p$. Fields of characteristic 0, finite fields and algebraically closed fields are perfect; $\mathbb{F}_p(t)$ is not ($x^p - t$ is irreducible and inseparable).*

(c) Let $F \subseteq K \subseteq L$ be finite extensions inside $\overline{\mathbb{F}}$. Every F-embedding $K \to \overline{\mathbb{F}}$ has exactly $[L : K]_s$ extensions to L. Hence $[L : F]_s = [L : K]_s [K : F]_s$.

(d) For L/F finite, $[L:F]_s$ divides $[L:F]$, and $[L:F]_s = [L:F]$ iff L/F is separable. In particular $L = F(\alpha_1, \dots, \alpha_r)$ with all α_i separable is separable over F, and for $F \subseteq K \subseteq L$ finite, L/F is separable iff L/K and K/F are.

(e) Over a perfect field every algebraic extension is separable.

Proof. (a) As f is irreducible, $\gcd(f, f')$ is 1 or f (up to units); it is f iff $f \mid f'$, iff $f' = 0$ since $\deg f' < \deg f$. Writing $f = \sum a_i x^i$, $f' = \sum i a_i x^{i-1}$ vanishes iff $ia_i = 0$ for all i; in characteristic 0 this forces f constant, and in characteristic p it means $a_i = 0$ unless $p \mid i$. For the second statement let e be the largest integer with $f \in F[x^{p^e}]$ and $f(x) = g(x^{p^e})$. A factorisation of g would give one of f, so g is irreducible, and $g \notin F[x^p]$ by maximality of e, so g is separable. If $g = \prod_j (x - \gamma_j)$ with distinct γ_j (leading coefficient omitted) and $\beta_j \in \overline{\mathbb{F}}$ with $\beta_j^{p^e} = \gamma_j$, then $x^{p^e} - \gamma_j = (x - \beta_j)^{p^e}$ (the p-th power map is additive), so $f = \prod_j (x - \beta_j)^{p^e}$ with distinct β_j.

(b) In characteristic 0 apply (a). In characteristic p with $F = F^p$: an inseparable irreducible $f = \sum a_i x^{pi}$ would be $\left(\sum b_i x^i\right)^p$ with $b_i^p = a_i$, not irreducible. If $a \in F \setminus F^p$, let $\alpha^p = a$ in $\overline{\mathbb{F}}$; then $x^p - a = (x - \alpha)^p$, and a monic factor in $F[x]$ is $(x - \alpha)^k$ with $0 < k < p$, whose coefficient of x^{k-1} is $-k\alpha \notin F$ (as $\alpha \notin F$ and $k \in \mathbb{F}_p^\times$); so $x^p - a$ is irreducible and inseparable. For a finite field the Frobenius $x \mapsto x^p$ is injective, hence surjective (Chapter 2); over an algebraically closed field irreducible polynomials have degree 1. For $\mathbb{F}_p(t)$, $t \notin \mathbb{F}_p(t)^p$ (compare degrees in t).

(c) Fix an F-embedding $\sigma\colon K \to \overline{\mathbb{F}}$. If $L = K(\beta)$, the extensions of σ correspond to the distinct roots of $\sigma(m_{\beta,K})$ (Theorem 5.10(b)). Write $m_{\beta,K} = g(x^{p^e})$ as in (a) ($e = 0$ in characteristic 0). Then $\sigma(m_{\beta,K}) = \sigma(g)(x^{p^e})$, and $\sigma(g)$ is separable because $\gcd(\sigma(g), \sigma(g)') = \sigma(\gcd(g, g')) = 1$; by the argument of (a), $\sigma(m_{\beta,K})$ has exactly $\deg g$ distinct roots, a number independent of σ. Taking σ the inclusion, it is $[L:K]_s$. For general $L = K(\beta_1, \dots, \beta_s)$ extend in steps. For the formula: every F-embedding of L restricts to an F-embedding of K, and each of the $[K:F]_s$ embeddings of K has exactly $[L:K]_s$ extensions, so $\#\mathrm{Emb}_F(L, \overline{\mathbb{F}}) = [K:F]_s[L:K]_s$.

(d) For $L = F(\alpha)$: $[L:F]_s$ is the number of distinct roots of $m_{\alpha,F}$, which is $\deg m_{\alpha,F} = [L:F]$ if α is separable and, by (a), $\deg g = [L:F]/p^e$ with $e \geq 1$ otherwise. So $[F(\alpha):F]_s$ divides $[F(\alpha):F]$, with equality iff α is separable. In general write $L = F(\alpha_1, \dots, \alpha_r)$ and use (c) and the tower law along $F_i = F(\alpha_1, \dots, \alpha_i)$: $[L:F]_s = \prod [F_{i+1}:F_i]_s$ divides $\prod [F_{i+1}:F_i] = [L:F]$. If L/F is separable, each α_{i+1} is separable over F, hence over F_i (its minimal polynomial over F_i divides that over F), so equality holds factor by factor. Conversely, if $[L:F]_s = [L:F]$ and $\alpha \in L$, then $[L:F(\alpha)]_s[F(\alpha):F]_s = [L:F(\alpha)][F(\alpha):F]$ with each factor on the left at most the corresponding one on the right, so $[F(\alpha):F]_s = [F(\alpha):F]$ and α is separable. The last two statements follow from the equality criterion and multiplicativity.

(e) Every irreducible polynomial over a perfect field is separable. □

For the paper, separability is never an obstacle. Every field that occurs there ($\mathbb{Q}$, number fields, $\mathbb{Q}_q$ and its finite extensions such as the unramified ones, the finite residue fields $\mathbb{F}_q$, and the algebraic closures of these) has characteristic 0 or is finite, hence is perfect by (b), so every algebraic extension in sight is separable and $F^{\mathrm{sep}} = \overline{\mathbb{F}}$. The general notion is kept so that the theorems below can be stated in their natural generality. To see what goes wrong without it, let $F = \mathbb{F}_p(t)$ and $\alpha \in \overline{\mathbb{F}}$ with $\alpha^p = t$. The minimal polynomial of α is $x^p - t = (x - \alpha)^p$ (irreducible by (b)), so $[F(\alpha):F] = p$, while α is the only root and $[F(\alpha):F]_s = 1$: there is a single F-embedding $F(\alpha) \to \overline{\mathbb{F}}$, and $\mathrm{Aut}(F(\alpha)/F)$ is trivial although the degree is p.

Theorem 5.17 (Primitive element)**.** *(a) A finite separable extension L/F is simple: $L = F(\theta)$ for some $\theta \in L$. If F is infinite and $L = F(\alpha, \beta)$, one can take $\theta = \alpha + c\beta$ for all but finitely many $c \in F$.*

(b) A finite extension L/F is simple iff it has only finitely many intermediate fields.

Proof. (a) If F is finite, so is L, and $L^\times$ is cyclic (Chapter 2); a generator θ of $L^\times$ satisfies $L = F(\theta)$. Let F be infinite. A finite separable L is generated by finitely many separable elements (for instance an F-basis), and by induction on their number it suffices to treat $L = F(\alpha, \beta)$: if $F(\alpha_1, \alpha_2) = F(\theta_1)$, then $F(\alpha_1, \alpha_2, \alpha_3) = F(\theta_1, \alpha_3)$ has one generator fewer. In the two-generator case we only need β separable. Let $\alpha = \alpha_1, \dots, \alpha_n$ be the roots of $m_{\alpha,F}$ and $\beta = \beta_1, \dots, \beta_m$ the distinct roots of $g = m_{\beta,F}$ in $\overline{\mathbb{F}}$. For each i and each $j \neq 1$ the equation $\alpha_i + c\beta_j = \alpha + c\beta$ has at most one solution c; choose $c \in F$ avoiding these finitely many values and put $\theta = \alpha + c\beta$. The polynomials $g(x)$ and $h(x) = m_{\alpha,F}(\theta - cx)$ lie in $F(\theta)[x]$ and both vanish at β. If $h(\beta_j) = 0$ with $j \neq 1$, then $\theta - c\beta_j = \alpha_i$ for some i, which c was chosen to avoid. So β is the only common root of g and h in $\overline{\mathbb{F}}$, and it is a simple root of g; hence $\gcd(g, h) = x - \beta$ in $\overline{\mathbb{F}}[x]$. The gcd of two polynomials of $F(\theta)[x]$ is computed by the Euclidean algorithm inside $F(\theta)[x]$ and does not change when the field is enlarged (the remark before Proposition 5.16); so $x - \beta \in F(\theta)[x]$, that is $\beta \in F(\theta)$, and then $\alpha = \theta - c\beta \in F(\theta)$.

(b) Suppose $L = F(\theta)$ and let M be intermediate, $g = m_{\theta,M}$, and $M_0 \subseteq M$ the field generated over F by the coefficients of g. Then g is irreducible over M_0 (a factorisation over M_0 would be one over the larger field M), $g(\theta) = 0$ and $L = M_0(\theta)$, so $[L : M_0] = \deg g = [L : M]$, and $M_0 \subseteq M$ gives $M = M_0$. Thus M is determined by g, a monic divisor of $m_{\theta,F}$ in $L[x]$, of which there are finitely many: in $\overline{\mathbb{F}}[x]$, $m_{\theta,F} = \prod_{i=1}^{n}(x - \theta_i)$ with $n = [L : F]$, and by unique factorisation every monic divisor is the product of the factors $x - \theta_i$ over a sub-multiset, so there are at most 2^n of them. Conversely, suppose there are finitely many intermediate fields. If F is finite, (a) applies. If F is infinite and $L = F(\alpha, \beta)$, the fields $F(\alpha + c\beta)$, $c \in F$, cannot all differ, so $F(\alpha + c\beta) = F(\alpha + c'\beta) =: M$ for some $c \neq c'$; then M contains $(c - c')\beta$, hence β and α, and $L = M$ is simple. Induction on the number of generators finishes the proof. □

For example, take $L = \mathbb{Q}(2^{1/3}, \zeta_3)$, the splitting field of $x^3 - 2$ (Example 5.31), with $\alpha = 2^{1/3}$ and $\beta = \zeta_3$, whose conjugates are $\alpha_i = \zeta_3^i\alpha$ and $\beta_2 = \zeta_3^2$. The values of c to avoid are the solutions of $\alpha_i + c\beta_2 = \alpha + c\beta$, namely $c = (\zeta_3^i - 1)\alpha/(\zeta_3 - \zeta_3^2)$, $i = 0, 1, 2$. For $i = 0$ this is $c = 0$; for $i = 1, 2$ it is not real, since $\zeta_3 - \zeta_3^2 = i\sqrt{3}$ and $(\zeta_3^{\pm 1} - 1)/(i\sqrt{3}) = (1 \pm i\sqrt{3})/2$. So every $c \in \mathbb{Q}^\times$ works, and $\theta = 2^{1/3} + \zeta_3$ generates L. Its minimal polynomial is the resultant $\operatorname{res}_y\big((x-y)^3 - 2,\ y^2 + y + 1\big) = x^6 + 3x^5 + 6x^4 + 3x^3 + 9x + 9$, which PARI confirms is irreducible.

Proposition 5.18 (Separable closure)**.** *F^{sep} is a subfield of $\overline{\mathbb{F}}$, normal and separable over F, and every separable algebraic extension of F inside $\overline{\mathbb{F}}$ lies in it. If F is perfect then $F^{\mathrm{sep}} = \overline{\mathbb{F}}$; in particular $\mathbb{Q}^{\mathrm{sep}} = \overline{\mathbb{Q}}$, $\mathbb{F}_q^{\mathrm{sep}} = \overline{\mathbb{F}}_q$ and $\mathbb{Q}_p^{\mathrm{sep}} = \overline{\mathbb{Q}}_p$.*

Proof. If $\alpha, \beta \in \overline{\mathbb{F}}$ are separable over F, then $F(\alpha, \beta)/F$ is separable by Proposition 5.16(d), so $\alpha \pm \beta$, $\alpha\beta$, α/β are separable: F^{sep} is a field, separable over F by definition. If $\alpha \in F^{\mathrm{sep}}$, all roots of $m_{\alpha,F}$ have the same separable minimal polynomial, so they lie in F^{sep}: condition (i) of Proposition 5.14 holds. The rest is the definition and Proposition 5.16(e). □

5.3 Galois extensions and the fundamental theorem

This section proves the fundamental theorem of Galois theory for finite extensions: subgroups of the Galois group correspond to intermediate fields. Every "fixed field", "cut out by" and "subgroup of index two" in the paper is an instance: the first sentence of the proof of Proposition prop:ns, that the image of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$ is the determinant-one subgroup combines the fundamental

theorem with Proposition 5.66. The translation theorem at the end is what makes restriction of representations to G_K well behaved, and in Chapter 7 it says that an unramified base change does not change the inertia group (the first sentence of the proof of Lemma lem:tamagawa-exp).

Theorem 5.19 (Dedekind's lemma)**.** *Let G be a monoid, L a field and $\chi_1, \dots, \chi_n \colon G \to L^\times$ distinct monoid homomorphisms. If $a_1, \dots, a_n \in L$ satisfy $\sum_i a_i \chi_i(g) = 0$ for all $g \in G$, then $a_1 = \cdots = a_n = 0$. In particular distinct field embeddings $\sigma_1, \dots, \sigma_n \colon K \to L$ are linearly independent over L (apply the lemma to $G = K^\times$).*

Proof. Suppose not, and take a nontrivial relation $\sum_i a_i \chi_i = 0$ with the least number of nonzero coefficients; renumber so that $a_1, \dots, a_m \neq 0$ and the others vanish. Then $m \geq 2$: for $m = 1$ the relation would read $a_1 \chi_1(g) = 0$ for all g, and $\chi_1(g) \in L^\times$ would force $a_1 = 0$. Choose h with $\chi_1(h) \neq \chi_2(h)$. For all g, $\sum_{i \leq m} a_i \chi_i(hg) = \sum_{i \leq m} a_i \chi_i(h) \chi_i(g) = 0$, and $\chi_1(h) \sum_{i \leq m} a_i \chi_i(g) = 0$. Subtracting, $\sum_{2 \leq i \leq m} a_i (\chi_i(h) - \chi_1(h)) \chi_i(g) = 0$, a relation with fewer nonzero coefficients whose coefficient at $i = 2$ is nonzero: a contradiction. □

For two embeddings the lemma is a two-line computation: if $a \cdot 1 + b \cdot \sigma = 0$ on $\mathbb{Q}(\sqrt{2})$, $\sigma(\sqrt{2}) = -\sqrt{2}$, then evaluating at 1 and at $\sqrt{2}$ gives $a + b = 0$ and $(a - b)\sqrt{2} = 0$, so $a = b = 0$. The lemma enters below through Hilbert's Theorem 90 (Theorem 5.34) and the non-vanishing of the trace (Proposition 5.33(d)); in both cases the χ_i are the elements of a Galois group, restricted to $L^\times$.

Theorem 5.20 (Artin)**.** *(a) Let L be a field, $G \subseteq \mathrm{Aut}(L)$ a finite group and $F = L^G = \{x \in L : \sigma(x) = x \text{ for all } \sigma \in G\}$. Then L/F is finite, normal and separable, $[L : F] = \#G$ and $\mathrm{Aut}(L/F) = G$. For $\alpha \in L$, $m_{\alpha,F} = \prod_{\beta \in G\alpha}(x - \beta)$, the product over the orbit.*

(b) For every finite extension L/F, $\#\mathrm{Aut}(L/F) \leq [L : F]_s \leq [L : F]$, and $\#\mathrm{Aut}(L/F) = [L : F]$ iff L/F is normal and separable.

Proof. (a) Let $\alpha \in L$ with orbit $G\alpha = \{\beta_1, \dots, \beta_k\}$, $k \leq \#G$. The polynomial $P = \prod_j (x - \beta_j)$ has distinct roots, and every $\sigma \in G$ permutes them, so its coefficients are fixed by G: $P \in F[x]$. If $g \in F[x]$ vanishes at α, it vanishes at each $\sigma(\alpha)$, so $P \mid g$; hence $P = m_{\alpha,F}$. Thus every $\alpha \in L$ is algebraic and separable over F of degree at most $\#G$, and its minimal polynomial splits in L: L/F is algebraic, separable and normal. Every finite subextension K/F of L is separable, hence $K = F(\theta)$ (Theorem 5.17), and $[K : F] \leq \#G$. Choose such a K of maximal degree; for $\beta \in L$, $K(\beta)$ is again finite over F, so $K(\beta) = K$. Hence $L = K$ and $[L : F] \leq \#G$. On the other hand $G \subseteq \mathrm{Aut}(L/F)$, and by (b) $\#\mathrm{Aut}(L/F) \leq [L : F]$. So $\#G \leq \#\mathrm{Aut}(L/F) \leq [L : F] \leq \#G$, all are equal and $G = \mathrm{Aut}(L/F)$.

(b) Embed L in $\overline{\mathbb{F}}$. Composing with the inclusion $L \subseteq \overline{\mathbb{F}}$ makes $\mathrm{Aut}(L/F)$ a subset of $\mathrm{Emb}_F(L, \overline{\mathbb{F}})$, of size $[L : F]_s \leq [L : F]$ (Proposition 5.16(d)). If L/F is normal and separable, every F-embedding has image L (Proposition 5.14), so $\mathrm{Aut}(L/F) = \mathrm{Emb}_F(L, \overline{\mathbb{F}})$ has $[L : F]_s = [L : F]$ elements. Conversely, if $\#\mathrm{Aut}(L/F) = [L : F]$, then $[L : F]_s = [L : F]$, so L/F is separable, and $\mathrm{Aut}(L/F) = \mathrm{Emb}_F(L, \overline{\mathbb{F}})$, so every embedding has image L and L/F is normal. □

Part (a) manufactures Galois extensions out of groups. For example, let k be a field, $L = k(t)$ the field of rational functions and $G = \{1, \iota\}$ with $\iota(r(t)) = r(1/t)$, an automorphism of order 2. The element $u = t + 1/t$ lies in L^G, and t is a root of $x^2 - ux + 1 \in k(u)[x]$, so $[L : k(u)] \leq 2$. As $k(u) \subseteq L^G$ and $[L : L^G] = \#G = 2$, the tower law gives $L^G = k(u)$, and (a) gives $m_{t,L^G} = (x - t)(x - 1/t) = x^2 - ux + 1$, the product over the orbit of t.

Definition 5.21 (Galois extensions)**.** An algebraic extension L/F is *Galois* if it is normal and separable. Its *Galois group* is $\mathrm{Gal}(L/F) = \mathrm{Aut}(L/F)$.

The two conditions fail independently. The extension $\mathbb{Q}(2^{1/3})/\mathbb{Q}$ is separable but not normal, and the identity is its only automorphism: an automorphism sends $2^{1/3}$ to a root of x^3-2 in the real field $\mathbb{Q}(2^{1/3})$, and $2^{1/3}$ is the only real root. $\mathbb{F}_p(t^{1/p})/\mathbb{F}_p(t)$ is normal (the only root of $x^p - t$ is $t^{1/p}$) but not separable, and again its automorphism group is trivial. In both cases the automorphism group is too small to see the extension; the next theorem shows that being Galois is exactly the condition $\#\,\mathrm{Aut}(L/F) = [L:F]$.

Theorem 5.22 (Characterisations of finite Galois extensions)**.** *For a finite extension L/F the following are equivalent:*

(i) L/F *is Galois;*

(ii) L *is the splitting field over* F *of a separable polynomial;*

(iii) $L^{\mathrm{Aut}(L/F)} = F$*;*

(iv) $\#\,\mathrm{Aut}(L/F) = [L:F]$.

If L/F is Galois and $F \subseteq M \subseteq L$, then L/M is Galois.

Proof. (i)⇔(iv) is Theorem 5.20(b). (i)⇒(ii): $L = F(\theta)$ (Theorem 5.17); $m_{\theta,F}$ is separable, splits in L by normality, and its roots generate L. (ii)⇒(iv): by Theorem 5.12(b) with $\phi = \mathrm{id}$, $L = L'$, the identity of F has exactly $[L:F]$ extensions to automorphisms of L. (i)⇒(iii): put $G = \mathrm{Aut}(L/F)$ and $F' = L^G \supseteq F$. By Theorem 5.20(a), $[L:F'] = \#G = [L:F]$, so $F' = F$. (iii)⇒(i): $G = \mathrm{Aut}(L/F)$ is finite (Theorem 5.20(b)), and Theorem 5.20(a) shows that $L/L^G = L/F$ is normal and separable. Finally, if L is the splitting field over F of a separable f, it is the splitting field of f over M. □

Theorem 5.23 (Fundamental theorem of Galois theory)**.** *Let L/F be a finite Galois extension with group $G = \mathrm{Gal}(L/F)$.*

(a) The maps $H \mapsto L^H$ and $M \mapsto \mathrm{Gal}(L/M)$ are mutually inverse, inclusion-reversing bijections between the subgroups $H \leq G$ and the intermediate fields $F \subseteq M \subseteq L$.

(b) $[L:M] = \#\,\mathrm{Gal}(L/M)$ *and* $[M:F] = [G:\mathrm{Gal}(L/M)]$.

(c) For $\sigma \in G$, $\mathrm{Gal}(L/\sigma M) = \sigma\,\mathrm{Gal}(L/M)\sigma^{-1}$.

(d) M/F is Galois iff $\mathrm{Gal}(L/M)$ *is normal in G. Then restriction $\sigma \mapsto \sigma|_M$ is a surjection $G \to \mathrm{Gal}(M/F)$ with kernel* $\mathrm{Gal}(L/M)$*, so* $G/\,\mathrm{Gal}(L/M) \simeq \mathrm{Gal}(M/F)$.

(e) The compositum M_1M_2 corresponds to $\mathrm{Gal}(L/M_1) \cap \mathrm{Gal}(L/M_2)$*, and $M_1 \cap M_2$ to the subgroup generated by* $\mathrm{Gal}(L/M_1)$ *and* $\mathrm{Gal}(L/M_2)$.

Proof. (a), (b). For $H \leq G$, Theorem 5.20(a) gives $[L:L^H] = \#H$ and $\mathrm{Gal}(L/L^H) = H$. For M intermediate, L/M is Galois (Theorem 5.22), so $L^{\mathrm{Gal}(L/M)} = M$ by (iii) there. Both maps reverse inclusions. The tower law gives $[M:F] = [L:F]/[L:M] = \#G/\#\,\mathrm{Gal}(L/M)$. (c) For $m \in M$, $\tau(\sigma(m)) = \sigma(m)$ iff $\sigma^{-1}\tau\sigma(m) = m$; so τ fixes σM pointwise iff $\sigma^{-1}\tau\sigma \in \mathrm{Gal}(L/M)$, that is iff $\tau \in \sigma\,\mathrm{Gal}(L/M)\sigma^{-1}$. (d) The extension M/F is separable. Every F-embedding

$M \to \overline{\mathbb{F}}$ (with $L \subseteq \overline{\mathbb{F}}$) extends to an F-embedding $L \to \overline{\mathbb{F}}$ (Theorem 5.10(b)), which has image L because L/F is normal, so it is an element of G. Hence the F-embeddings of M are the $\sigma|_M$, $\sigma \in G$, and by Proposition 5.14(iii) M/F is normal iff $\sigma M = M$ for all $\sigma \in G$, iff (by (a) and (c)) $\sigma \operatorname{Gal}(L/M)\sigma^{-1} = \operatorname{Gal}(L/M)$ for all σ. In that case $\sigma \mapsto \sigma|_M$ is a homomorphism $G \to \operatorname{Gal}(M/F)$, surjective because every automorphism of M/F is an embedding and so extends, as just shown, with kernel $\operatorname{Gal}(L/M)$. (e) σ fixes M_1M_2 iff it fixes M_1 and M_2 (the fixed field of σ is a field). An element fixed by $H_1 = \operatorname{Gal}(L/M_1)$ and by $H_2 = \operatorname{Gal}(L/M_2)$ is fixed by every product of their elements, so the fixed field of the subgroup generated by H_1 and H_2 is $L^{H_1} \cap L^{H_2} = M_1 \cap M_2$; apply (a). □

Example 5.31 below works out the whole correspondence for a group of order 6, including the conjugate subgroups of (c) and the normal subgroup of (d); the reader may want to look at it now.

Proposition 5.24 (Translation)**.** *Let L/F be finite Galois and M/F any extension, with L and M contained in a common field. Then LM/M is finite Galois, and restriction* $\operatorname{Gal}(LM/M) \to \operatorname{Gal}(L/F)$, $\sigma \mapsto \sigma|_L$, *is injective with image* $\operatorname{Gal}(L/L \cap M)$. *Consequently:*

(a) $[LM : M] = [L : L \cap M]$; in particular $[LM : M]$ divides $[L : F]$.

(b) If L_1, L_2 are finite Galois over F, so are L_1L_2 and $L_1 \cap L_2$, and $\operatorname{Gal}(L_1L_2/F) \to \operatorname{Gal}(L_1/F) \times \operatorname{Gal}(L_2/F)$, $\sigma \mapsto (\sigma|_{L_1}, \sigma|_{L_2})$, *is injective, with image the pairs that agree on $L_1 \cap L_2$; it is bijective iff $L_1 \cap L_2 = F$.*

Proof. Let L be the splitting field over F of a separable f with roots $r_1, \dots, r_n$. Then $LM = M(r_1, \dots, r_n)$ is the splitting field of f over M, so LM/M is Galois. An element $\sigma \in \operatorname{Gal}(LM/M)$ permutes the r_i, so $\sigma(L) = L$ and $\sigma|_L \in \operatorname{Gal}(L/F)$; if $\sigma|_L = \mathrm{id}$, then σ fixes M and L, hence LM. Let H be the image. An element $x \in L$ fixed by H is fixed by $\operatorname{Gal}(LM/M)$, so $x \in M$ (Theorem 5.22(iii)); hence $L^H = L \cap M$ (the inclusion $\supseteq$ being clear) and $H = \operatorname{Gal}(L/L \cap M)$ by Theorem 5.23(a). (a) Count. (b) L_1L_2 is the splitting field of the product of the distinct irreducible factors of f_1f_2, which is separable; $L_1 \cap L_2$ is normal by Proposition 5.14(i) (an irreducible polynomial over F with a root in $L_1 \cap L_2$ splits in L_1 and in L_2, so all its roots lie in $L_1 \cap L_2$), and separable as a subfield of L_1. The map is injective as L_1L_2 is generated by L_1 and L_2. Its image lies in the set of pairs agreeing on $L_1 \cap L_2$, which has $\#\operatorname{Gal}(L_1/F) \cdot \#\operatorname{Gal}(L_2/L_1 \cap L_2)$ elements: given $\sigma_1 \in \operatorname{Gal}(L_1/F)$, the $\sigma_2 \in \operatorname{Gal}(L_2/F)$ with $\sigma_2|_{L_1 \cap L_2} = \sigma_1|_{L_1 \cap L_2}$ form one coset of $\operatorname{Gal}(L_2/L_1 \cap L_2)$, nonempty because restriction $\operatorname{Gal}(L_2/F) \to \operatorname{Gal}(L_1 \cap L_2/F)$ is surjective (Theorem 5.23(d)). By (a), $\#\operatorname{Gal}(L_1L_2/F) = [L_1L_2 : L_1][L_1 : F] = [L_2 : L_1 \cap L_2][L_1 : F]$ is the same number, so the injective map is onto this set. □

The hypothesis that L/F be Galois cannot be dropped. Let $\alpha = 2^{1/3}$, $L = \mathbb{Q}(\alpha)$ and $M = \mathbb{Q}(\zeta_3\alpha)$. Then $L \neq M$ ($L \subset \mathbb{R}$, $M \not\subset \mathbb{R}$), so $L \cap M$, whose degree over $\mathbb{Q}$ divides 3 and is not 3, is $\mathbb{Q}$. But LM contains $\zeta_3 = \zeta_3\alpha/\alpha$, so it is the splitting field of $x^3 - 2$, of degree 6, and $[LM : M] = 2 \neq 3 = [L : L \cap M]$. With the Galois extension $L = \mathbb{Q}(\zeta_3)$ and $M = \mathbb{Q}(\alpha)$ instead, the proposition applies: $L \cap M = \mathbb{Q}$ and $[LM : M] = 6/3 = 2 = [L : \mathbb{Q}]$.

5.4 Finite fields, quadratic and cyclotomic extensions

The three families of Galois extensions that the paper uses constantly are worked out here. Finite fields give the residue fields $\mathbb{F}_q$ of Lemmas lem:tamfactor and lem:euler and the honest

model of a Frobenius element; quadratic fields give the characters χ_d of the table of Section 1, of Lemma lem:twist and of Theorem thm:twist; cyclotomic fields give $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$ (Proposition prop:ns, Lemma lem:h0) and the field $\mathbb{Q}(\sqrt{\ell^*}) \subset \mathbb{Q}(\zeta_\ell)$ of the hypothesis of Theorem thm:main. The section ends with the splitting field of $x^3 - 2$, the model of a non-abelian Galois group and of a quadratic subfield cut out by a sign.

Theorem 5.25 (Galois theory of finite fields)**.** *Let $q = p^r$ and $n \geq 1$, and work inside a fixed algebraic closure $\overline{\mathbb{F}}_p$; $\mathbb{F}_q$ is the unique subfield with q elements.*

(a) $\mathbb{F}_{q^n} = \{x \in \overline{\mathbb{F}}_p : x^{q^n} = x\}$ is the splitting field of $x^{q^n} - x$ over $\mathbb{F}_q$, it is the unique extension of $\mathbb{F}_q$ of degree n inside $\overline{\mathbb{F}}_p$, and every extension of $\mathbb{F}_q$ of degree n is $\mathbb{F}_q$-isomorphic to it.

(b) $\mathbb{F}_{q^n}/\mathbb{F}_q$ is Galois, and $\mathrm{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q)$ is cyclic of order n, generated by $\mathrm{Frob}_q \colon x \mapsto x^q$.

(c) The intermediate fields of $\mathbb{F}_{q^n}/\mathbb{F}_q$ are the $\mathbb{F}_{q^d}$ with $d \mid n$, and $\mathbb{F}_{q^d}$ is the fixed field of $\langle \mathrm{Frob}_q^d \rangle$.

(d) If $g \in \mathbb{F}_q[x]$ is irreducible of degree d with a root α, then $\mathbb{F}_q(\alpha) = \mathbb{F}_{q^d}$ and g has the d distinct roots $\alpha, \alpha^q, \ldots, \alpha^{q^{d-1}}$ in $\mathbb{F}_{q^d}$. Every finite extension of a finite field is Galois with cyclic group.

The smallest example to keep in mind: $x^2 + x + 1$ is the only irreducible quadratic over $\mathbb{F}_2$ (each of x^2, $x^2 + 1 = (x+1)^2$, $x^2 + x$ has a root), so $\mathbb{F}_4 = \mathbb{F}_2(\omega) = \{0, 1, \omega, \omega + 1\}$ with $\omega^2 = \omega + 1$. Here $\mathrm{Frob}_2(\omega) = \omega^2 = \omega + 1$ is the other root of $x^2 + x + 1$, as (d) says; Frob_2 swaps ω and $\omega + 1$, fixes exactly $\mathbb{F}_2$, and generates $\mathrm{Gal}(\mathbb{F}_4/\mathbb{F}_2) \simeq \mathbb{Z}/2$.

Proof. (a) The polynomial $x^{q^n} - x$ has derivative -1, so it is separable, and its q^n roots in $\overline{\mathbb{F}}_p$ form a field (Chapter 2: the roots of $x^{p^m} - x$ are closed under the field operations). It contains $\mathbb{F}_q$, whose elements satisfy $x^q = x$. A subextension $K \subseteq \overline{\mathbb{F}}_p$ of degree n over $\mathbb{F}_q$ has q^n elements, all satisfying $x^{q^n} = x$ (Lagrange in $K^\times$), so $K = \mathbb{F}_{q^n}$ by counting. An abstract extension of degree n embeds over $\mathbb{F}_q$ into $\overline{\mathbb{F}}_p$ (Theorem 5.10(b)), with image $\mathbb{F}_{q^n}$. (b) Frob_q is an injective ring endomorphism of the finite field $\mathbb{F}_{q^n}$, hence an automorphism; it fixes $\mathbb{F}_q$. Its powers Frob_q^k, $1 \leq k < n$, are not the identity, since $x^{q^k} = x$ has at most $q^k < q^n$ solutions. So $\langle \mathrm{Frob}_q \rangle \subseteq \mathrm{Aut}(\mathbb{F}_{q^n}/\mathbb{F}_q)$ has order $n = [\mathbb{F}_{q^n} : \mathbb{F}_q]$, and Theorem 5.20(b) gives equality and that the extension is Galois. (c) The subgroups of the cyclic group of order n are the $\langle \mathrm{Frob}_q^d \rangle$, $d \mid n$, of order n/d; the fixed field of Frob_q^d is $\{x : x^{q^d} = x\} = \mathbb{F}_{q^d}$. Apply Theorem 5.23. (d) $\mathbb{F}_q(\alpha)$ has degree d, so it is $\mathbb{F}_{q^d}$ by (a), Galois over $\mathbb{F}_q$. The roots of g form the orbit of α under $\mathrm{Gal}(\mathbb{F}_{q^d}/\mathbb{F}_q) = \langle \mathrm{Frob}_q \rangle$ (Theorem 5.20(a)), namely the $\mathrm{Frob}_q^i(\alpha) = \alpha^{q^i}$, $0 \leq i < d$, which are distinct since the orbit has $\deg g = d$ elements. □

Proposition 5.26 (Cyclotomic polynomials modulo p)**.** *Let $n \geq 1$, p a prime with $p \nmid n$, f the order of p in $(\mathbb{Z}/n)^\times$, and $\bar{\Phi}_n \in \mathbb{F}_p[x]$ the reduction of Φ_n. Then $\bar{\Phi}_n = \prod_\zeta (x - \zeta)$, the product over the $\varphi(n)$ elements of order exactly n in $\overline{\mathbb{F}}_p^\times$; it is the product of $\varphi(n)/f$ distinct monic irreducible polynomials of degree f; and $\mathbb{F}_p(\mu_n) = \mathbb{F}_{p^f}$.*

Proof. As $p \nmid n$, $x^m - 1$ is separable over $\mathbb{F}_p$ for every $m \mid n$ (its derivative mx^{m-1} is prime to it), so $\mu_n(\overline{\mathbb{F}}_p)$ is a group of order n, cyclic (Chapter 2), with exactly $\varphi(n)$ elements of order n. Reducing $x^m - 1 = \prod_{e \mid m} \Phi_e$ (Chapter 2) modulo p, the roots of $\prod_{e \mid m} \bar{\Phi}_e$ are the elements of order dividing m, each once. The roots of $\bar{\Phi}_n$ are therefore the roots of $x^n - 1$ that are not roots of $\bar{\Phi}_e$ for any proper divisor e of n, that is, which have order dividing no proper divisor of n:

the elements of order exactly n. Let ζ be one. By Theorem 5.25(d) its minimal polynomial over $\mathbb{F}_p$ has the roots ζ^{p^i}, $0 \le i < d$, where d is the least integer with $\zeta^{p^d} = \zeta$, that is, with $p^d \equiv 1 \pmod{n}$; so $d = f$ for every ζ. Grouping the $\varphi(n)$ roots into these orbits gives $\varphi(n)/f$ distinct irreducible factors of degree f, and $\mathbb{F}_p(\mu_n) = \mathbb{F}_p(\zeta) = \mathbb{F}_{p^f}$. □

This is the finite-field shadow of the decomposition of p in $\mathbb{Q}(\zeta_n)$: in Chapter 6 it gives that $p \nmid n$ splits into $\varphi(n)/f$ primes of residue degree f, and that Frob_p is σ_p (Theorem 5.72).

For instance, take $n = 5$, $\Phi_5 = x^4 + x^3 + x^2 + x + 1$. The order of 2 and of 3 modulo 5 is 4, so Φ_5 is irreducible modulo 2 and modulo 3. As $11 \equiv 1 \pmod{5}$, Φ_5 splits into four linear factors modulo 11; its roots are $3, 4, 5, 9$, the elements of order 5 of $\mathbb{F}_{11}^\times$. As $19 \equiv 4 \pmod{5}$ has order 2, modulo 19 it is a product of two irreducible quadratics, $(x^2 + 5x + 1)(x^2 + 15x + 1)$ (PARI). Since every element of $(\mathbb{Z}/8)^\times$ has order at most 2, $\Phi_8 = x^4 + 1$, irreducible over $\mathbb{Q}$, is reducible modulo every odd prime.

Proposition 5.27 (Quadratic extensions)**.** *Let* $\operatorname{char} F \neq 2$.

(a) Every extension L/F of degree 2 is Galois and equals $F(\sqrt{d})$ for some $d \in F^\times \setminus F^{\times 2}$; $\mathrm{Gal}(L/F) = \{1, \sigma\}$ with $\sigma(\sqrt{d}) = -\sqrt{d}$.

(b) Inside $\overline{\mathbb{F}}$, $F(\sqrt{d}) = F(\sqrt{d'})$ iff $d/d' \in F^{\times 2}$. So $d \mapsto F(\sqrt{d})$ is a bijection from the nontrivial elements of $F^\times/F^{\times 2}$ to the quadratic extensions of F in $\overline{\mathbb{F}}$.

(c) The quadratic fields are the $\mathbb{Q}(\sqrt{d})$, $d \neq 0, 1$ a squarefree integer, pairwise distinct.

(d) If the classes of $a, b \in F^\times$ in $F^\times/F^{\times 2}$ are independent (that is, none of a, b, ab is a square), then $F(\sqrt{a}, \sqrt{b})/F$ is Galois with group $\{\pm 1\}^2 \simeq V_4$, the element (ϵ_1, ϵ_2) acting by $\sqrt{a} \mapsto \epsilon_1\sqrt{a}$, $\sqrt{b} \mapsto \epsilon_2\sqrt{b}$; its quadratic subfields are exactly $F(\sqrt{a})$, $F(\sqrt{b})$ and $F(\sqrt{ab})$.

Proof. (a) Let $\alpha \in L \setminus F$, so $L = F(\alpha)$ and $m_{\alpha,F} = x^2 + bx + c$. Then $(\alpha + b/2)^2 = b^2/4 - c =: d$, and d is not a square in F (otherwise $\alpha \in F$), so $L = F(\sqrt{d})$ with $\sqrt{d} = \alpha + b/2$. The roots $\pm\sqrt{d}$ are distinct as $d \neq 0$ and $2 \neq 0$, so L is the splitting field of the separable $x^2 - d$, Galois of degree 2, and the nontrivial automorphism sends $\sqrt{d}$ to the other root. (b) If $d' = dt^2$, then $\sqrt{d'} = \pm t\sqrt{d}$. Conversely if $\sqrt{d'} = x + y\sqrt{d}$ with $x, y \in F$, squaring gives $d' = x^2 + y^2 d + 2xy\sqrt{d}$, so $xy = 0$ (as $1, \sqrt{d}$ is a basis and $2 \neq 0$); $y = 0$ would make d' a square, so $x = 0$ and $d' = y^2 d$. With (a) this is the bijection. (c) Every class in $\mathbb{Q}^\times/\mathbb{Q}^{\times 2}$ has a unique squarefree integer representative. (d) $\sqrt{b} \notin F(\sqrt{a})$: otherwise $F(\sqrt{b}) = F(\sqrt{a})$ (both of degree 2), and $ab = a^2(b/a)$ would be a square by (b). So $[F(\sqrt{a}, \sqrt{b}) : F] = 4$; the field is the splitting field of the separable $(x^2 - a)(x^2 - b)$, hence Galois, and an automorphism is determined by the signs ϵ_1, ϵ_2, all four occurring by counting: the group has $[F(\sqrt{a}, \sqrt{b}) : F] = 4$ elements (Theorem 5.22) and there are four sign pairs. The three subgroups of order 2 are generated by $(1, -1)$, $(-1, 1)$ and $(-1, -1)$, which fix $\sqrt{a}$, $\sqrt{b}$ and $\sqrt{ab} = \pm\sqrt{a}\sqrt{b}$ respectively; by Theorem 5.23 the three quadratic subfields are $F(\sqrt{a})$, $F(\sqrt{b})$, $F(\sqrt{ab})$. □

Theorem 5.28 (Cyclotomic fields)**.** *Let $n \ge 1$, $\zeta_n = e^{2\pi i/n}$, $\mu_n = \langle \zeta_n \rangle \subset \overline{\mathbb{Q}}$, and $\Phi_n = \prod_{1 \le a \le n,\ (a,n)=1} (x - \zeta_n^a) \in \mathbb{Z}[x]$ (Chapter 2).*

(a) Φ_n is irreducible over $\mathbb{Q}$; so $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \varphi(n)$.

(b) $\mathbb{Q}(\zeta_n)/\mathbb{Q}$ is Galois, and $a \mapsto \sigma_a$, where $\sigma_a(\zeta) = \zeta^a$ for all $\zeta \in \mu_n$, is an isomorphism $(\mathbb{Z}/n)^\times \to \mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$, which does not depend on the choice of a primitive n-th root of unity.

(c) *For $m \mid n$, restriction* $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \to \mathrm{Gal}(\mathbb{Q}(\zeta_m)/\mathbb{Q})$ *is reduction* $(\mathbb{Z}/n)^\times \to (\mathbb{Z}/m)^\times$. *For all m, n:* $\mathbb{Q}(\zeta_m)\mathbb{Q}(\zeta_n) = \mathbb{Q}(\zeta_{\mathrm{lcm}(m,n)})$ *and* $\mathbb{Q}(\zeta_m) \cap \mathbb{Q}(\zeta_n) = \mathbb{Q}(\zeta_{\gcd(m,n)})$*;* $\mathbb{Q}(\zeta_n) = \mathbb{Q}(\zeta_{2n})$ *for odd n. Every subfield of* $\mathbb{Q}(\zeta_n)$ *is Galois over* $\mathbb{Q}$ *with abelian group.*

(d) $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$, *since* $(2\zeta_3+1)^2 = -3$*;* $\mathbb{Q}(\zeta_4) = \mathbb{Q}(i)$*;* $\mathbb{Q}(\zeta_8) = \mathbb{Q}(i, \sqrt{2})$, *since* $\zeta_8 + \zeta_8^{-1} = \sqrt{2}$, *with the three quadratic subfields* $\mathbb{Q}(i)$, $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{-2})$.

Proof. (a) Let ζ be a primitive n-th root of unity and g its minimal polynomial over $\mathbb{Q}$, a monic factor of the monic $\Phi_n \in \mathbb{Z}[x]$; by Gauss's lemma (Chapter 2) $g \in \mathbb{Z}[x]$ and $\Phi_n = gh$ with $h \in \mathbb{Z}[x]$ monic. We show: *if $p \nmid n$ is prime, then $g(\zeta^p) = 0$.* If not, ζ^p (a primitive n-th root of unity, as $p \nmid n$) is a root of h, so ζ is a root of $h(x^p)$, and $g \mid h(x^p)$ in $\mathbb{Q}[x]$, hence in $\mathbb{Z}[x]$ by Gauss's lemma: $h(x^p) = g(x)k(x)$ with $k \in \mathbb{Z}[x]$. Reduce modulo p: since $\bar{h}$ has coefficients in $\mathbb{F}_p$, $\bar{h}(x^p) = \bar{h}(x)^p$. So $\bar{g}\bar{k} = \bar{h}^p$, and any irreducible factor π of $\bar{g}$ in $\mathbb{F}_p[x]$ divides $\bar{h}$. Then π^2 divides $\bar{g}\bar{h} = \bar{\Phi}_n$, which divides $x^n - 1$ in $\mathbb{F}_p[x]$; but $x^n - 1$ is separable over $\mathbb{F}_p$ because $p \nmid n$. This contradiction proves the claim. Now every primitive root is ζ^a with $(a, n) = 1$, $a = p_1 \cdots p_k$ a product of primes not dividing n; applying the claim successively to $\zeta, \zeta^{p_1}, \zeta^{p_1 p_2}, \ldots$ (all primitive, all roots of the same g) gives $g(\zeta^a) = 0$. So all $\varphi(n)$ roots of Φ_n are roots of g, and $g = \Phi_n$. (b) $\mathbb{Q}(\zeta_n)$ contains all primitive n-th roots of unity (powers of ζ_n), so it is the splitting field of the separable Φ_n, Galois of degree $\varphi(n)$. An automorphism σ sends ζ_n to a root of Φ_n, so $\sigma(\zeta_n) = \zeta_n^a$ with $a \in (\mathbb{Z}/n)^\times$ determined by σ, and then $\sigma(\zeta_n^k) = \zeta_n^{ak}$: $\sigma = \sigma_a$ acts on all of μ_n by $\zeta \mapsto \zeta^a$, which does not mention ζ_n. As $\sigma_a\sigma_b(\zeta) = \sigma_a(\zeta^b) = \zeta^{ab}$, $a \mapsto \sigma_a$ is an injective homomorphism, bijective by counting. (c) $\zeta_m = \zeta_n^{n/m}$, so $\sigma_a(\zeta_m) = \zeta_m^a = \zeta_m^{a \bmod m}$. Let $g = \gcd(m, n)$, $s = \mathrm{lcm}(m, n)$ and $um + vn = g$ with $u, v \in \mathbb{Z}$. Then $\zeta_m^v \zeta_n^u = e^{2\pi i(vn+um)/mn} = e^{2\pi i g/mn} = \zeta_s$, so $\mathbb{Q}(\zeta_m)\mathbb{Q}(\zeta_n) \supseteq \mathbb{Q}(\zeta_s)$, and the converse inclusion is clear. By Proposition 5.24(a), $[\mathbb{Q}(\zeta_m) \cap \mathbb{Q}(\zeta_n) : \mathbb{Q}] = [\mathbb{Q}(\zeta_m) : \mathbb{Q}]\,[\mathbb{Q}(\zeta_n) : \mathbb{Q}]/[\mathbb{Q}(\zeta_s) : \mathbb{Q}] = \varphi(m)\varphi(n)/\varphi(s)$, and $\varphi(m)\varphi(n) = \varphi(s)\varphi(g)$ (from $\varphi(k) = k\prod_{p|k}(1 - 1/p)$ and $mn = sg$, the primes dividing s being those dividing m or n, those dividing g those dividing both). So the intersection has degree $\varphi(g)$ and contains $\mathbb{Q}(\zeta_g)$: they are equal. For odd n, $\mathbb{Q}(\zeta_n) \subseteq \mathbb{Q}(\zeta_{2n})$ and $\varphi(2n) = \varphi(n)$. Subgroups of the abelian group $(\mathbb{Z}/n)^\times$ are normal, so Theorem 5.23(d) applies. (d) $(2\zeta_3+1)^2 = 4(\zeta_3^2 + \zeta_3 + 1) - 3 = -3$, and both fields have degree 2. $\zeta_8 + \zeta_8^{-1} = 2\cos(\pi/4) = \sqrt{2}$; $\mathbb{Q}(i, \sqrt{2}) \subseteq \mathbb{Q}(\zeta_8)$ and both have degree 4. The quadratic subfields follow from Proposition 5.27(d) with $a = -1$, $b = 2$. □

Proposition 5.29 (The field $\mathbb{Q}(\sqrt{\ell^*})$)**.** *Let ℓ be an odd prime and $\ell^* = (-1)^{(\ell-1)/2}\ell$.*

(a) *The Gauss sum $g = \sum_{a=1}^{\ell-1}\left(\frac{a}{\ell}\right)\zeta_\ell^a$ satisfies $g^2 = \ell^*$ and $\sigma_a(g) = \left(\frac{a}{\ell}\right)g$ for $a \in (\mathbb{Z}/\ell)^\times$. In particular $\sqrt{\ell^*} = \pm g \in \mathbb{Q}(\zeta_\ell)$.*

(b) $\mathbb{Q}(\sqrt{\ell^*})$ *is the unique quadratic subfield of $\mathbb{Q}(\zeta_\ell)$, the fixed field of the subgroup of squares of $(\mathbb{Z}/\ell)^\times$, and $\sigma_a(\sqrt{\ell^*}) = \left(\frac{a}{\ell}\right)\sqrt{\ell^*}$. In terms of characters of $G_\mathbb{Q}$ (Definition 5.58): for $\sigma \in G_\mathbb{Q}$,*

$$\chi_{\ell^*}(\sigma) = \left(\frac{\bar{\chi}_\ell(\sigma)}{\ell}\right) = \bar{\chi}_\ell(\sigma)^{(\ell-1)/2},$$

the last equality in $\mathbb{F}_\ell^\times \supseteq \{\pm 1\}$ (Euler's criterion). Briefly, $\chi_{\ell^*} = \bar{\chi}_\ell^{(\ell-1)/2}$.

(c) *For $\ell = 3$:* $\mathbb{Q}(\sqrt{-3}) = \mathbb{Q}(\zeta_3)$ *and $\chi_{-3} = \bar{\chi}_3$. For $\ell \geq 5$: $\chi_{\ell^*} \neq \bar{\chi}_\ell$, since $\bar{\chi}_\ell$ has order $\ell - 1 > 2$.*

(d) Every quadratic field $\mathbb{Q}(\sqrt{d})$, d squarefree, lies in $\mathbb{Q}(\zeta_{|D|})$, where $D = d$ if $d \equiv 1 \pmod 4$ and $D = 4d$ otherwise is its discriminant. In particular, for a finite set S of odd primes, $\mathbb{Q}(\sqrt{\prod_{q\in S} q^*}) \subseteq \mathbb{Q}(\zeta_{\prod_{q\in S} q})$.

Proof. (a) $g^2 = \ell^*$ is Chapter 2 (the quadratic Gauss sum). For a prime to ℓ, $\sigma_a(g) = \sum_b (\frac{b}{\ell})\zeta_\ell^{ab} = (\frac{a}{\ell})\sum_b (\frac{ab}{\ell})\zeta_\ell^{ab} = (\frac{a}{\ell})g$, as $b \mapsto ab$ permutes $(\mathbb{Z}/\ell)^\times$ and $(\frac{a}{\ell})^2 = 1$. (b) $(\mathbb{Z}/\ell)^\times$ is cyclic of even order $\ell - 1$ (Chapter 2), so it has exactly one subgroup of index 2, the squares; by Theorem 5.23 $\mathbb{Q}(\zeta_\ell)$ has exactly one quadratic subfield, the fixed field of the squares. By (a), g is fixed exactly by the σ_a with $(\frac{a}{\ell}) = 1$, and $g \notin \mathbb{Q}$ (it is moved by σ_a for a non-residue a), so that subfield is $\mathbb{Q}(g) = \mathbb{Q}(\sqrt{\ell^*})$. For $\sigma \in G_\mathbb{Q}$, $\sigma|_{\mathbb{Q}(\zeta_\ell)} = \sigma_a$ with $a \equiv \bar\chi_\ell(\sigma)$ (Definition 5.58), so $\chi_{\ell^*}(\sigma) = \sigma(g)/g = (\frac{a}{\ell})$, and $(\frac{a}{\ell}) \equiv a^{(\ell-1)/2} \pmod \ell$. (c) $\mathbb{Q}(\sqrt{-3}) = \mathbb{Q}(\zeta_3)$ is Theorem 5.28(d); with $\ell = 3$, $(\ell-1)/2 = 1$. For $\ell \geq 5$, $\bar\chi_\ell$ is surjective onto the cyclic group $\mathbb{F}_\ell^\times$ of order $\ell - 1 \geq 4$ (Proposition 5.59), while $\chi_{\ell^*}^2 = 1$. (d) Write $d = \pm 2^e \prod_i q_i$ with $e \in \{0, 1\}$ and distinct odd primes q_i; then $d = \epsilon 2^e \prod_i q_i^*$ with $\epsilon = \pm 1$, and $\sqrt{q_i^*} \in \mathbb{Q}(\zeta_{q_i})$ by (b). If $d \equiv 1 \pmod 4$, then $e = 0$ and $\epsilon = 1$, because $\prod q_i^* \equiv 1 \pmod 4$ while $-\prod q_i^* \equiv 3 \pmod 4$; so $\sqrt{d} \in \mathbb{Q}(\zeta_{|d|})$. If $d \equiv 3 \pmod 4$, $e = 0$ and $\sqrt{d} = i\prod \sqrt{q_i^*}$ up to sign, in $\mathbb{Q}(\zeta_{4|d|})$ ($i \in \mathbb{Q}(\zeta_4)$, Theorem 5.28(c)). If d is even, $d = 2d_1$ with d_1 odd and squarefree; $\sqrt{2} = \zeta_8 + \zeta_8^{-1}$ lies in $\mathbb{Q}(\zeta_8)$, and $\sqrt{d_1} \in \mathbb{Q}(\zeta_{4|d_1|})$ by the two odd cases (or trivially if $d_1 = \pm 1$), so $\sqrt{d} = \pm\sqrt{2}\sqrt{d_1} \in \mathbb{Q}(\zeta_8)\mathbb{Q}(\zeta_{4|d_1|}) = \mathbb{Q}(\zeta_{8|d_1|}) = \mathbb{Q}(\zeta_{4|d|})$ by Theorem 5.28(c). The last statement is the case $d = \prod_{q\in S} q^* \equiv 1 \pmod 4$, up to the squarefree representative, which here is d itself. □

The two smallest cases make (a) concrete. For $\ell = 3$ (with $\zeta_3 = e^{2\pi i/3}$), $g = \zeta_3 - \zeta_3^2 = i\sqrt{3}$, a square root of -3. For $\ell = 5$, the squares modulo 5 are $1, 4$, and $g = (\zeta_5 + \zeta_5^4) - (\zeta_5^2 + \zeta_5^3) = 2\cos(2\pi/5) - 2\cos(4\pi/5) = \frac{\sqrt{5}-1}{2} + \frac{\sqrt{5}+1}{2} = \sqrt{5}$. In both cases g is the square root of ℓ^* that is positive or has positive imaginary part; that this holds for every ℓ is Gauss's determination of the sign, which the book does not need.

In the paper 5.30. The hypothesis of Theorem thm:main concerns $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell^*})) = \ker \chi_{\ell^*}$, the subgroup of index 2 of $G_\mathbb{Q}$ on which $\bar\chi_\ell$ takes square values. For $\ell = 3$ it is $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\zeta_3)) = \ker \bar\chi_3$; this coincidence $\chi_{-3} = \bar\chi_3$ is why Lemma lem:h0 can phrase the exceptional case both as $\bar\rho \simeq \bar\rho \otimes \bar\chi_3$ and as $\bar\rho \simeq \bar\rho \otimes \chi_{-3}$. For $\ell \geq 5$ the two characters differ, and Section 1.3 of the paper states the criterion with $\bar\chi_\ell$ (see Proposition 5.64(c) and Proposition 5.67).

Example 5.31 (The splitting field of $x^3 - 2$)**.** Let $\alpha = 2^{1/3} \in \mathbb{R}$, $\zeta = \zeta_3$ and $L = \mathbb{Q}(\alpha, \zeta)$, the splitting field of $x^3 - 2$ (roots $\alpha, \zeta\alpha, \zeta^2\alpha$). As $[\mathbb{Q}(\alpha) : \mathbb{Q}] = 3$ and $[\mathbb{Q}(\zeta) : \mathbb{Q}] = 2$ divide $[L : \mathbb{Q}] \leq 6$, $[L : \mathbb{Q}] = 6$. Let $\sigma \in \mathrm{Gal}(L/\mathbb{Q})$ fix ζ and send $\alpha \mapsto \zeta\alpha$, and let τ be complex conjugation, which fixes α and sends $\zeta \mapsto \zeta^2$ (both exist by Theorem 5.12(b): the extensions of $\mathbb{Q}(\zeta) \to \mathbb{Q}(\zeta)$, identity or conjugation, to L are determined by the image of α, any of the three roots). Then $\sigma^3 = \tau^2 = 1$ and $\tau\sigma\tau(\alpha) = \tau(\zeta\alpha) = \zeta^2\alpha = \sigma^{-1}(\alpha)$, $\tau\sigma\tau(\zeta) = \zeta = \sigma^{-1}(\zeta)$, so $\tau\sigma\tau = \sigma^{-1}$ and $\mathrm{Gal}(L/\mathbb{Q}) \simeq S_3$, acting faithfully on the three roots. One computes $\sigma\tau(\zeta^2\alpha) = \zeta^4 \cdot \zeta\alpha = \zeta^2\alpha$ and $\sigma^2\tau(\zeta\alpha) = \zeta^2 \cdot \zeta^2\alpha = \zeta\alpha$; so each subgroup of order 2 is the stabiliser of the root it fixes, and the correspondence of Theorem 5.23 is:

subgroup	fixed field	degree over $\mathbb{Q}$
$\{1\}$	L	6
$\langle\tau\rangle$	$\mathbb{Q}(\alpha)$	3
$\langle\sigma\tau\rangle$	$\mathbb{Q}(\zeta^2\alpha)$	3
$\langle\sigma^2\tau\rangle$	$\mathbb{Q}(\zeta\alpha)$	3
$\langle\sigma\rangle = A_3$	$\mathbb{Q}(\zeta) = \mathbb{Q}(\sqrt{-3})$	2
S_3	$\mathbb{Q}$	1

The three cubic fields are conjugate (Theorem 5.23(c)) and not normal; $\mathbb{Q}(\sqrt{-3})$ is the only normal subfield other than $\mathbb{Q}$ and L, cut out by the sign of the permutation of the roots, and $\operatorname{disc}(x^3-2) = -108 = -3\cdot 6^2$ (Proposition 5.44). This is the pattern of Proposition prop:ns in miniature: a group of permutations of roots, and the quadratic subfield cut out by the sign, which there is $\det\bar\rho_{E,3} = \chi_{-3}$. The group is also the affine group $\mathbb{Z}/3 \rtimes (\mathbb{Z}/3)^\times$ of Proposition 5.38.

5.5 Cyclic extensions: Hilbert 90, Kummer, Artin-Schreier

Kummer theory describes the abelian extensions of exponent dividing n of a field containing the n-th roots of unity: they are obtained by adjoining n-th roots, and the Galois action on an n-th root α of a is recorded by the character $\sigma \mapsto \sigma(\alpha)/\alpha$. The paper uses it twice. In Lemma lem:tamagawa-exp the ℓ^t-torsion of a Tate curve over $\mathbb{Q}_q^{\mathrm{ur}}$ is generated by μ_{ℓ^t} and an ℓ^t-th root of the Tate parameter q_E, and "by Kummer theory" inertia acts trivially iff q_E is an ℓ^t-th power; in Lemma lem:tamfactor the Galois action on $T_\ell E$ is given by the Kummer cocycle κ of q_E, whose unramified part is the class of the unit part of q_E in $\mathbb{F}_q^\times \otimes \mathbb{Z}_\ell$. The field-theoretic statements are proved here; the ℓ-adic cocycle is Proposition 5.70, and the cohomological form $H^1(K,\mu_n) \simeq K^\times/K^{\times n}$ is Chapter 17.

Definition 5.32 (Norm and trace)**.** Let L/F be finite separable of degree n and $\sigma_1,\dots,\sigma_n$ its F-embeddings into $\overline{\mathbb{F}}$. For $a \in L$, $\mathrm{N}_{L/F}(a) = \prod_i \sigma_i(a)$ and $\mathrm{Tr}_{L/F}(a) = \sum_i \sigma_i(a)$.

Proposition 5.33 (Norm and trace)**.** *Let L/F be finite separable of degree n and $a \in L$.*

(a) The characteristic polynomial of the F-linear map $m_a\colon x \mapsto ax$ of L is $m_{a,F}^{[L:F(a)]}$; hence $\mathrm{N}_{L/F}(a) = \det m_a$ and $\mathrm{Tr}_{L/F}(a) = \operatorname{tr} m_a$, and both lie in F.

(b) $\mathrm{N}_{L/F}$ is multiplicative and $\mathrm{Tr}_{L/F}$ is F-linear; for L/F Galois, $\mathrm{N}_{L/F}(a) = \prod_{\sigma\in\mathrm{Gal}(L/F)}\sigma(a)$.

(c) For $F \subseteq K \subseteq L$: $\mathrm{N}_{L/F} = \mathrm{N}_{K/F}\circ\mathrm{N}_{L/K}$ and $\mathrm{Tr}_{L/F} = \mathrm{Tr}_{K/F}\circ\mathrm{Tr}_{L/K}$.

(d) $\mathrm{Tr}_{L/F}$ is not identically zero.

Proof. (a) Let $K = F(a)$, $d = [K:F]$, $m = [L:K]$, and $y_1,\dots,y_m$ a K-basis of L. In the F-basis $(a^i y_j)$ of L (Proposition 5.6) the matrix of m_a is block diagonal with m copies of the companion matrix of $m_{a,F}$, whose characteristic polynomial is $m_{a,F}$. On the other side, each of the d embeddings of K (sending a to the d distinct roots $a_1,\dots,a_d$ of $m_{a,F}$) has exactly m extensions to L (Proposition 5.16(c), (d)), so $\prod_i\sigma_i(a) = (\prod_k a_k)^m$ and $\sum_i\sigma_i(a) = m\sum_k a_k$, which are the determinant and the trace of the block matrix. (b) Multiplicativity and linearity are clear from the definition (or from (a)). If L/F is Galois, the embeddings are the elements of $\mathrm{Gal}(L/F)$. (c) Every F-embedding of L is obtained, exactly once, by choosing an F-embedding

τ of K, extending it to an automorphism $\tilde\tau$ of $\overline{\mathbb{F}}$ (Theorem 5.10(d)), and composing with one of the K-embeddings $\rho_1,\dots,\rho_m$ of L; so $\mathrm{N}_{L/F}(a)=\prod_\tau\prod_j\tilde\tau\rho_j(a)=\prod_\tau\tau(\mathrm{N}_{L/K}(a))$, and similarly for the trace. (d) $\mathrm{Tr}_{L/F}=\sum_i\sigma_i$ is a nontrivial combination of distinct embeddings, nonzero by Theorem 5.19. □

Two examples show both descriptions at work. For $L=\mathbb{Q}(\sqrt{d})$ and $a=x+y\sqrt{d}$, the matrix of m_a in the basis $1,\sqrt{d}$ is $\left(\begin{smallmatrix}x & dy\\ y & x\end{smallmatrix}\right)$, so $\mathrm{N}(a)=x^2-dy^2=(x+y\sqrt{d})(x-y\sqrt{d})$ and $\mathrm{Tr}(a)=2x$. For $a=2^{1/3}\in\mathbb{Q}(2^{1/3})$, m_a sends the basis $1,a,a^2$ to $a,a^2,2$; its matrix has determinant 2 and trace 0, and indeed the conjugates a,ζ_3a,ζ_3^2a have product 2 and sum 0.

Theorem 5.34 (Hilbert's Theorem 90)**.** *(a) Let L/F be finite Galois with group G, and let $(a_\sigma)_{\sigma\in G}$ be elements of $L^\times$ with $a_{\sigma\tau}=a_\sigma\,\sigma(a_\tau)$ for all σ,τ. Then there is $c\in L^\times$ with $a_\sigma=\sigma(c)/c$ for all σ.*

(b) Let L/F be cyclic of degree n with $\mathrm{Gal}(L/F)=\langle\sigma\rangle$. For $b\in L^\times$: $\mathrm{N}_{L/F}(b)=1$ iff $b=c/\sigma(c)$ for some $c\in L^\times$.

(c) In the same situation, for $b\in L$: $\mathrm{Tr}_{L/F}(b)=0$ iff $b=c-\sigma(c)$ for some $c\in L$.

Proof. (a) By Theorem 5.19 the map $\sum_{\tau\in G}a_\tau\tau$ is not identically zero; choose θ with $c_0=\sum_\tau a_\tau\tau(\theta)\neq0$. For $\sigma\in G$, $\sigma(c_0)=\sum_\tau\sigma(a_\tau)\,\sigma\tau(\theta)=\sum_\tau a_\sigma^{-1}a_{\sigma\tau}\,\sigma\tau(\theta)=a_\sigma^{-1}c_0$. So $a_\sigma=c_0/\sigma(c_0)=\sigma(c)/c$ with $c=c_0^{-1}$. (b) If $b=c/\sigma(c)$, then $\mathrm{N}(b)=\mathrm{N}(c)/\mathrm{N}(\sigma c)=1$, the norm being the product over the group. Conversely, put $a_{\sigma^i}=b\,\sigma(b)\cdots\sigma^{i-1}(b)$ for $0\le i<n$ ($a_1=1$); this defines a on all of G, each element being σ^i for exactly one such i. For $0\le i,j<n$,

$$a_{\sigma^i}\,\sigma^i(a_{\sigma^j})=\prod_{k=0}^{i-1}\sigma^k(b)\cdot\prod_{k=i}^{i+j-1}\sigma^k(b)=\prod_{k=0}^{i+j-1}\sigma^k(b).$$

If $i+j<n$ this is $a_{\sigma^{i+j}}$ by definition. If $i+j\ge n$, then $\sigma^{i+j}=\sigma^{i+j-n}$ with $0\le i+j-n<n$, and as $\sigma^n=1$,

$$\prod_{k=0}^{i+j-1}\sigma^k(b)=\prod_{k=0}^{n-1}\sigma^k(b)\cdot\prod_{k=0}^{i+j-n-1}\sigma^k(b)=\mathrm{N}_{L/F}(b)\,a_{\sigma^{i+j-n}}=a_{\sigma^{i+j}}.$$

So the cocycle relation holds. By (a), $b=a_\sigma=\sigma(d)/d$ for some d; put $c=d^{-1}$. (c) If $b=c-\sigma(c)$, $\mathrm{Tr}(b)=0$. Conversely, choose θ with $\mathrm{Tr}\,\theta\neq0$ (Proposition 5.33(d)), put $s_i=b+\sigma(b)+\cdots+\sigma^i(b)$ (so $s_{n-1}=\mathrm{Tr}\,b=0$ and $\sigma(s_i)=s_{i+1}-b$) and $c=(\mathrm{Tr}\,\theta)^{-1}\sum_{i=0}^{n-2}s_i\sigma^{i+1}(\theta)$. Then

$$(\mathrm{Tr}\,\theta)\,\sigma(c)=\sum_{i=0}^{n-2}(s_{i+1}-b)\sigma^{i+2}(\theta)=\sum_{j=1}^{n-2}s_j\sigma^{j+1}(\theta)-b\sum_{j=2}^{n}\sigma^j(\theta),$$

using $s_{n-1}=0$. Subtracting from $(\mathrm{Tr}\,\theta)c=s_0\sigma(\theta)+\sum_{j=1}^{n-2}s_j\sigma^{j+1}(\theta)$ and using $s_0=b$ gives $(\mathrm{Tr}\,\theta)(c-\sigma(c))=b\sum_{j=1}^{n}\sigma^j(\theta)=b\,\mathrm{Tr}\,\theta$. □

For $L=\mathbb{Q}(i)$ and σ complex conjugation, (b) says that the points $x+iy$ with $x,y\in\mathbb{Q}$ on the circle $x^2+y^2=1$ are the quotients $c/\bar c$, $c=m+ni$ with $m,n\in\mathbb{Q}$ not both zero; and $c/\bar c=c^2/(c\bar c)=\frac{m^2-n^2}{m^2+n^2}+\frac{2mn}{m^2+n^2}\,i$ is the classical parametrisation of Pythagorean triples ($c=2+i$ gives $(3+4i)/5$). The shape of the condition in (a), $a_{\sigma\tau}=a_\sigma\,\sigma(a_\tau)$, depends on the convention that automorphisms compose as maps and act on the left (Convention 5.1); the same shape recurs in the cocycles b of Proposition 5.38 and κ_a of Proposition 5.70.

Proposition 5.35 (Kummer characters)**.** *Let $n \geq 1$, $\operatorname{char} F \nmid n$, and assume $\mu_n \subset F$ (so μ_n is cyclic of order n). Let $a \in F^\times$, $\alpha \in \overline{\mathbb{F}}$ with $\alpha^n = a$, and L/F a Galois extension containing α.*

(a) $\chi_a\colon \operatorname{Gal}(L/F) \to \mu_n$, $\sigma \mapsto \sigma(\alpha)/\alpha$, is a homomorphism that does not depend on the choice of α; its kernel is $\operatorname{Gal}(L/F(\alpha))$. Hence $F(\alpha)/F$ is Galois with cyclic group $\simeq \chi_a(\operatorname{Gal}(L/F))$, of order d equal to the order of the class of a in $F^\times/F^{\times n}$; in particular $d \mid n$.

(b) $\chi_{ab} = \chi_a\chi_b$, and $\chi_a = 1$ iff $a \in F^{\times n}$. So if L contains an n-th root of every element of $F^\times$ (for instance $L = F^{\mathrm{sep}}$), $a \mapsto \chi_a$ is an injective homomorphism $F^\times/F^{\times n} \to \operatorname{Hom}(\operatorname{Gal}(L/F), \mu_n)$.

(c) The minimal polynomial of α is $x^d - \alpha^d$, and $x^n - a$ is irreducible over F iff $a \notin F^{\times p}$ for every prime $p \mid n$.

Without the assumption $\mu_n \subset F$ the irreducibility criterion is Capelli's theorem: $x^n - a$ is irreducible iff $a \notin F^{\times p}$ for every prime $p \mid n$ and $a \notin -4F^{\times 4}$ when $4 \mid n$ (for example $x^4 + 4 = (x^2 + 2x + 2)(x^2 - 2x + 2)$). We do not prove this; see [109, Chapter VI, Theorem 9.1].

Proof. (a) The polynomial $x^n - a$ is separable ($a \neq 0$ and $n \neq 0$ in F), with the n roots $\zeta\alpha$, $\zeta \in \mu_n$, all in $F(\alpha)$; so $F(\alpha)$ is its splitting field, Galois over F. For $\sigma \in \operatorname{Gal}(L/F)$, $\sigma(\alpha)^n = \sigma(a) = a$, so $\chi_a(\sigma) = \sigma(\alpha)/\alpha \in \mu_n$. Another root is $\alpha' = \zeta\alpha$ with $\zeta \in \mu_n \subset F$ fixed by σ, so $\sigma(\alpha')/\alpha' = \sigma(\alpha)/\alpha$. Since $\chi_a(\tau) \in F$,

$$\chi_a(\sigma\tau) = \frac{\sigma(\tau(\alpha))}{\alpha} = \frac{\sigma(\chi_a(\tau)\alpha)}{\alpha} = \chi_a(\tau)\frac{\sigma(\alpha)}{\alpha} = \chi_a(\sigma)\chi_a(\tau).$$

The kernel consists of the σ fixing α, that is $\operatorname{Gal}(L/F(\alpha))$, and

$$\operatorname{Gal}(F(\alpha)/F) \simeq \operatorname{Gal}(L/F)/\operatorname{Gal}(L/F(\alpha)) \simeq \chi_a(\operatorname{Gal}(L/F)),$$

a subgroup of the cyclic group μ_n, of some order $d \mid n$. Then $\chi_a(\sigma)^d = 1$ for all σ, so α^d is fixed by $\operatorname{Gal}(L/F)$, $\alpha^d \in F$, and $a^d = (\alpha^d)^n \in F^{\times n}$. Conversely, if $a^k = b^n$ with $b \in F^\times$, then $(\alpha^k/b)^n = 1$, so $\alpha^k \in \mu_n b \subseteq F$ and $\chi_a(\sigma)^k = \sigma(\alpha^k)/\alpha^k = 1$ for all σ, whence $d \mid k$. So d is the order of a modulo $F^{\times n}$. (b) With $\alpha^n = a$, $\beta^n = b$, $(\alpha\beta)^n = ab$ and $\sigma(\alpha\beta)/\alpha\beta = \chi_a(\sigma)\chi_b(\sigma)$. $\chi_a = 1$ iff $\alpha \in F$ iff $a \in F^{\times n}$ (if $a = b^n$, then $\alpha \in \mu_n b \subseteq F$). (c) α is a root of $x^d - \alpha^d \in F[x]$, of degree $d = [F(\alpha) : F]$. So $x^n - a$ is irreducible iff $d = n$, iff the class of a in the group $F^\times/F^{\times n}$ of exponent n has order exactly n, iff $a^{n/p} \notin F^{\times n}$ for every prime $p \mid n$ (an element x with $x^n = 1$ has order exactly n iff $x^{n/p} \neq 1$ for every prime $p \mid n$, since every proper divisor of n divides some n/p). Finally $a^{n/p} \in F^{\times n}$ iff $a \in F^{\times p}$: if $a = b^p$, $a^{n/p} = b^n$; if $a^{n/p} = b^n$, then $(a/b^p)^{n/p} = 1$, so $a/b^p \in \mu_{n/p} = \{\zeta^p : \zeta \in \mu_n\}$ (μ_n being cyclic of order n), and a is a p-th power. □

For $n = 2$ the hypothesis $\mu_2 = \{\pm 1\} \subset F$ always holds (characteristic $\neq 2$), χ_a is the quadratic character $\sigma \mapsto \sigma(\sqrt{a})/\sqrt{a}$ of $F(\sqrt{a})$, and (c) says that $x^2 - a$ is irreducible iff a is not a square. For $n = 3$, $F = \mathbb{Q}(\zeta_3)$ and $a = 2$: 2 is not a cube in F, because a cube root of 2 has degree 3 over $\mathbb{Q}$ ($x^3 - 2$ is irreducible) and cannot lie in a field of degree 2. So $x^3 - 2$ is irreducible over $\mathbb{Q}(\zeta_3)$, $F(2^{1/3})$ is the field L of Example 5.31, and χ_2 maps $\operatorname{Gal}(L/\mathbb{Q}(\zeta_3)) = \langle\sigma\rangle$ isomorphically onto μ_3, with $\chi_2(\sigma) = \zeta_3$.

Theorem 5.36 (Cyclic extensions)**.** *Let $\operatorname{char} F \nmid n$ and $\mu_n \subset F$. Every cyclic extension L/F of degree n is of the form $L = F(c)$ with $c^n \in F^\times$.*

Proof. Let $\mathrm{Gal}(L/F) = \langle\sigma\rangle$ and ζ a primitive n-th root of unity. As $\zeta \in F$, $\mathrm{N}_{L/F}(\zeta^{-1}) = \zeta^{-n} = 1$, so by Theorem 5.34(b) $\zeta^{-1} = c/\sigma(c)$ for some $c \in L^\times$: $\sigma(c) = \zeta c$. Then $\sigma^i(c) = \zeta^i c$, $0 \le i < n$, are n conjugates of c, distinct because ζ has order n and $c \neq 0$; all are roots of $m_{c,F}$, so $[F(c) : F] \ge n = [L : F]$ and $F(c) = L$; and $\sigma(c^n) = c^n$, so $c^n \in F$. □

Theorem 5.37 (Kummer theory)**.** *Let* $\mathrm{char}\, F \nmid n$ *and* $\mu_n \subset F$*. For a subgroup* $F^{\times n} \subseteq \Delta \subseteq F^\times$ *let* $F_\Delta = F(\Delta^{1/n})$ *be the subfield of* F^{sep} *generated by all* α *with* $\alpha^n \in \Delta$*.*

(a) If $\Delta/F^{\times n}$ *is finite,* F_Δ/F *is a finite abelian extension of exponent dividing* n*, and*

$$\mathrm{Gal}(F_\Delta/F) \times \Delta/F^{\times n} \to \mu_n, \qquad (\sigma, a) \mapsto \sigma(\alpha)/\alpha \quad (\alpha^n = a),$$

is a well defined bilinear pairing which is perfect: it induces isomorphisms $\mathrm{Gal}(F_\Delta/F) \simeq \mathrm{Hom}(\Delta/F^{\times n}, \mu_n)$ *and* $\Delta/F^{\times n} \simeq \mathrm{Hom}(\mathrm{Gal}(F_\Delta/F), \mu_n)$*. In particular* $[F_\Delta : F] = [\Delta : F^{\times n}]$*.*

(b) $\Delta \mapsto F_\Delta$ *is an inclusion-preserving bijection from the groups* Δ *with* $\Delta/F^{\times n}$ *finite to the finite abelian extensions of* F *inside* F^{sep} *of exponent dividing* n*; the inverse is* $L \mapsto L^{\times n} \cap F^\times$*. The cyclic extensions of degree* d *correspond to the* Δ *with* $\Delta/F^{\times n}$ *cyclic of order* d*.*

The form without finiteness, $F^\times/F^{\times n} \simeq \mathrm{Hom}_{\mathrm{cont}}(G_F, \mu_n)$*, is Corollary 5.56.*

Proof. (a) Let $a_1, \dots, a_r$ represent generators of $\Delta/F^{\times n}$ and $\alpha_i^n = a_i$. If $\alpha^n = a \in \Delta$, write $a = b^n \prod a_i^{k_i}$ with $b \in F^\times$; then $\alpha/(b\prod \alpha_i^{k_i}) \in \mu_n \subset F$, so $F_\Delta = F(\alpha_1, \dots, \alpha_r)$, the splitting field of the separable $\prod_i (x^n - a_i)$, finite Galois. The pairing is well defined by Proposition 5.35(a) (independence of α) and (b) (χ_a depends only on a modulo $F^{\times n}$), and bilinear by the homomorphism property in each variable. If σ pairs trivially with all a, it fixes every α_i, so $\sigma = 1$; if a pairs trivially with all σ, then $\chi_a = 1$ and $a \in F^{\times n}$. So $G = \mathrm{Gal}(F_\Delta/F) \to \mathrm{Hom}(\Delta/F^{\times n}, \mu_n)$ and $\Delta/F^{\times n} \to \mathrm{Hom}(G, \mu_n)$ are injective. The first shows that G is abelian of exponent dividing n. For a finite abelian group A of exponent dividing n, $\#\,\mathrm{Hom}(A, \mu_n) = \#A$ (write A as a product of cyclic groups $\mathbb{Z}/m$ with $m \mid n$, Chapter 1, and note $\mathrm{Hom}(\mathbb{Z}/m, \mu_n) \simeq \mu_m$). Hence $\#G \le \#(\Delta/F^{\times n}) \le \#G$, both injections are bijections, and $[F_\Delta : F] = \#G = [\Delta : F^{\times n}]$.

(b) Let L/F be finite abelian of exponent dividing n and $\Delta_L = L^{\times n} \cap F^\times$. If $\beta \in L$ with $\beta^n = a \in F$, all n-th roots of a are $\zeta\beta \in L$; so $F_{\Delta_L} \subseteq L$, and in particular $\Delta_L/F^{\times n}$ is finite by (a) (it injects into $\mathrm{Hom}(\mathrm{Gal}(F_{\Delta_L}/F), \mu_n)$, the injectivity argument of (a) not using finiteness). Conversely, $A = \mathrm{Gal}(L/F)$ is a finite abelian group, and the intersection of the subgroups B with A/B cyclic is trivial (by the structure theorem, Chapter 1, for $1 \neq x \in A$ some projection to a cyclic factor is nonzero at x). By Theorem 5.23(e), L is the compositum of the fixed fields L^B, each cyclic of some degree $e \mid n$, hence $L^B = F(\beta)$ with $\beta^e \in F$ (Theorem 5.36, as $\mu_e \subseteq \mu_n \subset F$). Then $\beta^n = (\beta^e)^{n/e} \in F$, so $\beta \in F_{\Delta_L}$; hence $L = F_{\Delta_L}$. Finally $\Delta_{F_\Delta} = \Delta$: the inclusion $\supseteq$ is clear; if $a \in F^\times \cap F_\Delta^{\times n}$, the group Δ' generated by Δ and a has $F_{\Delta'} = F_\Delta$, so $[\Delta' : F^{\times n}] = [\Delta : F^{\times n}]$ by (a) and $a \in \Delta$. The two maps preserve inclusions. By (a), $\mathrm{Gal}(F_\Delta/F)$ is cyclic of order d iff its dual $\Delta/F^{\times n}$ is. □

For example, let $F = \mathbb{Q}$, $n = 2$ and Δ the group generated by $\mathbb{Q}^{\times 2}$, 2 and 3. Then $\Delta/\mathbb{Q}^{\times 2}$ consists of the classes of $1, 2, 3, 6$, $F_\Delta = \mathbb{Q}(\sqrt{2}, \sqrt{3})$, and the pairing identifies $\mathrm{Gal}(F_\Delta/\mathbb{Q}) \simeq V_4$ with the dual of $\Delta/\mathbb{Q}^{\times 2} \simeq (\mathbb{Z}/2)^2$. The three subgroups of order 2 of $\Delta/\mathbb{Q}^{\times 2}$, generated by 2, 3 and 6, correspond under (b) to the three quadratic subfields $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{3})$, $\mathbb{Q}(\sqrt{6})$ found in Proposition 5.27(d).

Proposition 5.38 (The affine shape without roots of unity)**.** *Let* $\operatorname{char} F \nmid n$, $a \in F^\times$, $\alpha^n = a$, $L = F(\mu_n, \alpha)$, *and fix a primitive* n*-th root of unity* ζ_n*. For* $\sigma \in \mathrm{Gal}(L/F)$ *define* $u(\sigma) \in (\mathbb{Z}/n)^\times$ *and* $b(\sigma) \in \mathbb{Z}/n$ *by* $\sigma(\zeta_n) = \zeta_n^{u(\sigma)}$ *and* $\sigma(\alpha) = \zeta_n^{b(\sigma)}\alpha$*. Then*

$$\sigma \longmapsto \begin{pmatrix} u(\sigma) & b(\sigma) \\ 0 & 1 \end{pmatrix}$$

is an injective homomorphism from $\mathrm{Gal}(L/F)$ *to the affine group* $\left\{ \left(\begin{smallmatrix} u & b \\ 0 & 1 \end{smallmatrix}\right) : u \in (\mathbb{Z}/n)^\times,\ b \in \mathbb{Z}/n \right\} \simeq \mathbb{Z}/n \rtimes (\mathbb{Z}/n)^\times$*. Equivalently,* $b(\sigma\tau) = b(\sigma) + u(\sigma)b(\tau)$*:* b *is a* 1*-cocycle for the action of* $\mathrm{Gal}(L/F)$ *on* $\mathbb{Z}/n$ *through* u*. Its restriction to* $\mathrm{Gal}(L/F(\mu_n))$ *(where* $u = 1$*) is the Kummer character* χ_a*, read in* $\mathbb{Z}/n$ *through* ζ_n*.*

Proof. L is the splitting field of the separable $x^n - a$ (its roots $\zeta\alpha$ generate μ_n and α), so it is Galois. We have $\sigma\tau(\zeta_n) = \sigma(\zeta_n^{u(\tau)}) = \zeta_n^{u(\sigma)u(\tau)}$ and $\sigma\tau(\alpha) = \sigma(\zeta_n^{b(\tau)}\alpha) = \zeta_n^{u(\sigma)b(\tau)}\zeta_n^{b(\sigma)}\alpha$, which is the matrix product $\left(\begin{smallmatrix} u(\sigma) & b(\sigma) \\ 0 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} u(\tau) & b(\tau) \\ 0 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} u(\sigma)u(\tau) & b(\sigma)+u(\sigma)b(\tau) \\ 0 & 1 \end{smallmatrix}\right)$. The map is injective since σ is determined by $\sigma(\zeta_n)$ and $\sigma(\alpha)$. □

The order of the factors reflects the convention $(\sigma\tau)(x) = \sigma(\tau(x))$: with automorphisms composed in the opposite order the same formulas would define an anti-homomorphism, and the cocycle relation would read $b(\sigma\tau) = b(\tau) + u(\tau)b(\sigma)$.

For $x^3 - 2$ over $\mathbb{Q}$ (Example 5.31) the Galois group has order 6 and embeds in the affine group of order 6, so $\mathrm{Gal} \simeq \mathbb{Z}/3 \rtimes (\mathbb{Z}/3)^\times \simeq S_3$. The ℓ-adic limit of this matrix, $\left(\begin{smallmatrix} \chi_\ell & \kappa_a \\ 0 & 1 \end{smallmatrix}\right)$, is Proposition 5.70; twisted by an unramified character ε of order at most 2 it becomes the matrix $\left(\begin{smallmatrix} \chi_\ell\varepsilon & \varepsilon\kappa \\ 0 & \varepsilon \end{smallmatrix}\right)$ of the proof of Lemma lem:tamfactor (Chapter 10).

Proposition 5.39 (Kummer theory over a finite field)**.** *Let* q *be a power of a prime* p*,* $\ell \neq p$ *a prime,* $v = v_\ell(q-1)$*, and* $u \in \mathbb{F}_q^\times$*.*

(a) For $1 \le k \le v$*,* $\mu_{\ell^k} \subset \mathbb{F}_q$*, and the Kummer character* χ_u *(with* $n = \ell^k$*) satisfies* $\chi_u(\mathrm{Frob}_q) = u^{(q-1)/\ell^k}$*. Hence* $u \in (\mathbb{F}_q^\times)^{\ell^k}$ *iff* $u^{(q-1)/\ell^k} = 1$*, and* $u \mapsto u^{(q-1)/\ell^v}$ *induces an isomorphism of cyclic groups of order* ℓ^v

$$\mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^v} \xrightarrow{\ \sim\ } \mu_{\ell^v}(\mathbb{F}_q);$$

the left side is also $\mathbb{F}_q^\times \otimes \mathbb{Z}_\ell$*.*

(b) Let $(\alpha_k)_{k\ge 0}$ *be a compatible system of* ℓ*-power roots of* u *in* $\overline{\mathbb{F}}_q$ *(*$\alpha_0 = u$*,* $\alpha_{k+1}^\ell = \alpha_k$*), and put* $\kappa_u(\mathrm{Frob}_q) = (\mathrm{Frob}_q(\alpha_k)/\alpha_k)_k = (\alpha_k^{q-1})_k \in \mathbb{Z}_\ell(1) = \varprojlim_k \mu_{\ell^k}(\overline{\mathbb{F}}_q)$*. Another compatible system changes* $\kappa_u(\mathrm{Frob}_q)$ *by an element of* $(q-1)\mathbb{Z}_\ell(1) = \ell^v\mathbb{Z}_\ell(1)$*. The class of* $\kappa_u(\mathrm{Frob}_q)$ *in* $\mathbb{Z}_\ell(1)/\ell^v\mathbb{Z}_\ell(1) \simeq \mu_{\ell^v}(\mathbb{F}_q)$ *is* $u^{(q-1)/\ell^v}$*, and for* $k \le v$ *it lies in* $\ell^k\mathbb{Z}_\ell(1)/\ell^v\mathbb{Z}_\ell(1)$ *iff* $u \in (\mathbb{F}_q^\times)^{\ell^k}$*.*

Proof. (a) $\mathbb{F}_q^\times$ is cyclic of order $q-1$ (Chapter 2), divisible by ℓ^k, so it contains μ_{ℓ^k}. If $\alpha^{\ell^k} = u$, then $\chi_u(\mathrm{Frob}_q) = \alpha^q/\alpha = \alpha^{q-1} = (\alpha^{\ell^k})^{(q-1)/\ell^k} = u^{(q-1)/\ell^k}$. As Frob_q generates $\mathrm{Gal}(\mathbb{F}_q(\alpha)/\mathbb{F}_q)$ (Theorem 5.25), $\chi_u = 1$ iff $\chi_u(\mathrm{Frob}_q) = 1$, and $\chi_u = 1$ iff $u \in (\mathbb{F}_q^\times)^{\ell^k}$ (Proposition 5.35(b)). The map $u \mapsto u^{(q-1)/\ell^v}$ is a homomorphism to $\mu_{\ell^v}(\mathbb{F}_q)$ with kernel $(\mathbb{F}_q^\times)^{\ell^v}$ (case $k = v$), surjective because a generator g of $\mathbb{F}_q^\times$ maps to an element of order ℓ^v. Writing $q - 1 = \ell^v m$ with $\ell \nmid m$, $\mathbb{F}_q^\times \simeq \mathbb{Z}/\ell^v \times \mathbb{Z}/m$ and $\mathbb{F}_q^\times \otimes \mathbb{Z}_\ell \simeq \mathbb{Z}/\ell^v$. (b) $(\alpha_k^{q-1})^{\ell^k} = u^{q-1} = 1$ and $(\alpha_{k+1}^{q-1})^\ell = \alpha_k^{q-1}$, so $(\alpha_k^{q-1})_k \in \mathbb{Z}_\ell(1)$. Another system is $(\epsilon_k\alpha_k)$ with $\epsilon = (\epsilon_k) \in \mathbb{Z}_\ell(1)$, and $(\epsilon_k\alpha_k)^{q-1} = \epsilon_k^{q-1}\alpha_k^{q-1}$: in additive notation the value changes by $(q-1)\epsilon$; and $(q-1)\mathbb{Z}_\ell(1) = \ell^v\mathbb{Z}_\ell(1)$ as $(q-1)/\ell^v \in \mathbb{Z}_\ell^\times$.

The projection to the v-th component identifies $\mathbb{Z}_\ell(1)/\ell^v\mathbb{Z}_\ell(1)$ with μ_{ℓ^v}, and the v-th component of $\kappa_u(\mathrm{Frob}_q)$ is $\alpha_v^{q-1} = u^{(q-1)/\ell^v}$ by (a). Finally, $\ell^k\mathbb{Z}_\ell(1)/\ell^v\mathbb{Z}_\ell(1)$ corresponds to $\mu_{\ell^{v-k}} = \mu_{\ell^v}^{\ell^k}$, and $u^{(q-1)/\ell^v} \in \mu_{\ell^{v-k}}$ iff $u^{(q-1)/\ell^k} = 1$, iff $u \in (\mathbb{F}_q^\times)^{\ell^k}$ by (a). □

For $\ell = 2$, q odd and $k = 1$, (a) is Euler's criterion: u is a square in $\mathbb{F}_q$ iff $u^{(q-1)/2} = 1$. A cubic example: $q = 7$, $\ell = 3$, so $v = 1$ and $(q-1)/3 = 2$. Then $u \in \mathbb{F}_7^\times$ is a cube iff $u^2 = 1$, that is $u = \pm 1$; indeed the cubes of $1, \dots, 6$ are $1, 1, 6, 1, 6, 6$. The class of $u = 3$ is $3^2 = 2$, a primitive cube root of unity in $\mathbb{F}_7$; so 3 is not a cube, $x^3 - 3$ is irreducible over $\mathbb{F}_7$ (Proposition 5.35(c)), and Frob_7 multiplies each cube root α of 3 by $\alpha^6 = 3^2 = 2$.

In the paper 5.40. Lemma lem:tamfactor defines $c(u)$ as the class of the reduction $\bar{u}$ of the unit part $u = q_E q^{-n}$ of the Tate parameter in $\mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^v}$, identified with $\mathbb{Z}/\ell^v$ by a choice of generator, and states that $v_\ell(c(u)) \geq k$ iff $\bar{u}$ is an ℓ^k-th power, for $k \leq v$, with $v_\ell(0)$ read as v. That is Proposition 5.39(a), (b): the valuation of the class does not depend on the generator, and the class is the value at Frob_q of the Kummer cocycle of $\bar{u}$, an element of $\mathbb{Z}_\ell(1)/(q-1) = \mathbb{F}_q^\times \otimes \mathbb{Z}_\ell$. In the proof of the lemma this class is the unramified part κ_u of the Kummer class $\kappa = n\kappa_q + \kappa_u$ of q_E; passing from $\mathbb{F}_q$ to $\mathbb{Q}_q$ needs Hensel's lemma and the inflation from $G_{\mathbb{Q}_q}/I_q$, which are Chapter 7 and Chapter 17. In Lemma lem:tamagawa-exp the field is $\mathbb{Q}_q^{\mathrm{ur}}$, which contains μ_{ℓ^t} because $q \neq \ell$ (Chapter 7), so Proposition 5.35(b) applies over it: inertia, which is $G_{\mathbb{Q}_q^{\mathrm{ur}}}$, fixes an ℓ^t-th root of q_E iff q_E is an ℓ^t-th power in $\mathbb{Q}_q^{\mathrm{ur}}$.

Theorem 5.41 (Artin-Schreier theory)**.** *Let* $\mathrm{char}\, F = p > 0$ *and* $\wp(b) = b^p - b$*, an additive map* $F \to F$ *with kernel* $\mathbb{F}_p$*.*

(a) For $a \in F$ *the polynomial* $x^p - x - a$ *is separable; if* α *is a root, its roots are* $\alpha + i$*,* $i \in \mathbb{F}_p$*. It splits over* F *if* $a \in \wp(F)$*, and is irreducible otherwise; then* $F(\alpha)/F$ *is cyclic of degree* p*, with group generated by* $\alpha \mapsto \alpha + 1$*.*

(b) Every cyclic extension of F *of degree* p *is* $F(\alpha)$ *with* $\alpha^p - \alpha \in F$*.*

(c) $\mathrm{Hom}_{\mathrm{cont}}(G_F, \mathbb{Z}/p) \simeq F/\wp(F)$*, the class of* a *corresponding to* $\sigma \mapsto \sigma(\alpha) - \alpha$ *(*$\wp(\alpha) = a$*).*

For example $x^p - x - 1$ *is irreducible over* $\mathbb{F}_p$ *(no element of* $\mathbb{F}_p$ *is a root, as* $\wp(\mathbb{F}_p) = 0$*), with splitting field* $\mathbb{F}_{p^p}$*.*

Proof of (a) and (b). (a) The derivative is -1, so the polynomial is separable; $(\alpha+i)^p-(\alpha+i)-a = \alpha^p-\alpha-a+i^p-i = 0$ for $i \in \mathbb{F}_p$. If one root lies in F, all do. Otherwise $F(\alpha)$ contains all roots, so it is Galois over F, and $\sigma \mapsto \sigma(\alpha)-\alpha \in \mathbb{F}_p$ is an injective homomorphism (as in Proposition 5.35(a), $\mathbb{F}_p$ being fixed) into $\mathbb{Z}/p$ with nontrivial image; so the group is $\mathbb{Z}/p$, $[F(\alpha) : F] = p$, and $x^p - x - a$ is irreducible. (b) Let $\mathrm{Gal}(L/F) = \langle\sigma\rangle$ of order p. Then $\mathrm{Tr}_{L/F}(-1) = -p = 0$, so Theorem 5.34(c) gives c with $-1 = c - \sigma(c)$, that is $\sigma(c) = c + 1$. Then $c \notin F$, so $L = F(c)$, and $\sigma(\wp(c)) = (c+1)^p - (c+1) = \wp(c)$, so $\wp(c) \in F$. □

Sketch of proof of (c). As in the proof of Corollary 5.56, with (a), (b) and the additive pairing $(\sigma, a) \mapsto \sigma(\alpha) - \alpha$ in place of the multiplicative one; see [109, Chapter VI, Section 8]. □

The name is shared with the Artin-Schreier theorem on real closed fields (Proposition 5.60(c)); the two are unrelated. Artin-Schreier extensions are the cyclic p-extensions that Kummer theory cannot reach in characteristic p; over the p-adic fields of Chapter 7, their analogues are the wildly ramified extensions behind Remark rem:wild of the paper.

5.6 The Galois group of a polynomial; discriminants, cubics, quartics and the four lines

The Galois group of a polynomial is the group of permutations of its roots induced by field automorphisms, and its orbits are the irreducible factors. This is the dictionary behind the last sentence of Proposition prop:ns: the four roots of the 3-division polynomial ψ_3 of E are the x-coordinates of the four lines of $E[3]$, so the factorisation of ψ_3 over $\mathbb{Q}$ records the orbits of the mod 3 image on the lines, and its discriminant records the determinant. It is also what the test `ns3` of the paper's appendix and the consistency check of Section sec:data compute. The discriminant, cubics and quartics are developed only as far as this application needs.

Proposition 5.42 (The Galois group of a polynomial)**.** *Let $f \in F[x]$ be separable of degree $n \geq 1$, $R \subseteq F^{\mathrm{sep}}$ its set of n roots, $L = F(R)$ its splitting field and $G_f = \mathrm{Gal}(L/F)$, the* Galois group of f*.*

(a) G_f acts faithfully on R; numbering the roots gives an injective homomorphism $G_f \to S_n$, whose image is well defined up to conjugation in S_n; $\#G_f = [L : F]$.

(b) The G_f-orbits on R are the root sets of the monic irreducible factors of f in $F[x]$: the orbit of r is the set of roots of $m_{r,F}$; its size is $[F(r) : F]$, and the stabiliser of r is $\mathrm{Gal}(L/F(r))$. In particular f is irreducible iff G_f is transitive on R, and then $n \mid \#G_f$.

(c) Let Ω/F be a Galois extension containing L (for instance $\Omega = F^{\mathrm{sep}}$). Then $\mathrm{Gal}(\Omega/F)$ acts on R through its quotient G_f, with the same orbits; and for every intermediate field $F \subseteq M \subseteq \Omega$, the irreducible factors of f in $M[x]$ correspond to the orbits of $\mathrm{Gal}(\Omega/M)$ on R.

Proof. (a) An automorphism of L/F permutes the roots of f and is determined by its values on the generators R. Renumbering conjugates the image; $\#G_f = [L : F]$ as L/F is Galois (Theorem 5.22). (b) Since f is separable, $f = c\prod_j g_j$ with distinct monic irreducible g_j, whose root sets partition R. For $r \in R$ and $\sigma \in G_f$, $\sigma(r)$ is a root of $m_{r,F}$; conversely, by Theorem 5.20(a) applied to G_f (with $L^{G_f} = F$), $m_{r,F} = \prod_{\beta \in G_f r}(x - \beta)$. So the orbit of r is the root set of $m_{r,F}$, of size $\deg m_{r,F} = [F(r) : F]$; σ fixes r iff it fixes $F(r)$. A transitive group has order divisible by the orbit size n. (c) Restriction $\mathrm{Gal}(\Omega/F) \to G_f$ is surjective (Theorem 5.23(d) for finite Ω; Theorem 5.52(d) in general), so the orbits are the same. Over M: f is separable in $M[x]$, Ω/M is Galois, and the first part applied over M (with splitting field $M(R) \subseteq \Omega$) gives the factors over M. □

For example, let $f = (x^2-2)(x^2-3)$ over $\mathbb{Q}$. Its splitting field is $L = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ and $G_f \simeq V_4$ (Proposition 5.27(d)), with the two orbits $\{\pm\sqrt{2}\}$ and $\{\pm\sqrt{3}\}$ on R, the root sets of the two factors. Numbering the roots $\sqrt{2}, -\sqrt{2}, \sqrt{3}, -\sqrt{3}$, the image of G_f in S_4 is $\langle (12), (34) \rangle$, the Klein group that is not normal in S_4; it reappears for $N_s(\mathbb{F}_3)$ in Proposition 5.47. Over $M = \mathbb{Q}(\sqrt{2})$ the group shrinks to $\mathrm{Gal}(L/M) = \langle (34) \rangle$, and $f = (x - \sqrt{2})(x + \sqrt{2})(x^2 - 3)$ in $M[x]$, as (c) predicts.

Definition 5.43 (Discriminant)**.** Let $f = a\prod_{i=1}^{n}(x - r_i)$ with $a \neq 0$ and roots r_i in $\overline{\mathbb{F}}$. Put $\delta_f = \prod_{i<j}(r_i - r_j)$ (which depends on the numbering up to sign) and $\mathrm{disc}(f) = a^{2n-2}\delta_f^2$. For monic $g = \prod_i (x - r_i)$ and $h = \prod_j (x - s_j)$, the resultant is $\mathrm{res}(g, h) = \prod_{i,j}(r_i - s_j)$ (written res to avoid confusion with the restriction Res).

Proposition 5.44 (Discriminants)**.** *Let $f = a\prod(x - r_i) \in F[x]$ have degree n.*

(a) $\operatorname{disc}(f) = (-1)^{n(n-1)/2}a^{n-2}\prod_{i=1}^{n} f'(r_i)$*; it lies in F, and it is nonzero iff f is separable.*

(b) If f is separable and $\sigma \in G_f \subseteq S_n$, then $\sigma(\delta_f) = \operatorname{sgn}(\sigma)\delta_f$.

(c) Let $\operatorname{char} F \neq 2$ *and f separable. Then $G_f \subseteq A_n$ iff* $\operatorname{disc}(f) \in F^{\times 2}$*. The fixed field of $G_f \cap A_n$ is $F(\delta_f) = F(\sqrt{\operatorname{disc} f})$, and the quadratic character of* $\operatorname{Gal}(F^{\mathrm{sep}}/F)$ *attached to it by Proposition 5.27 is the sign of the permutation of the roots: $\sigma(\sqrt{\operatorname{disc} f}) = \operatorname{sgn}(\sigma|_R)\sqrt{\operatorname{disc} f}$.*

(d) For monic g, h: $\operatorname{disc}(gh) = \operatorname{disc}(g)\operatorname{disc}(h)\operatorname{res}(g,h)^2$*.*

(e) $\operatorname{disc}(x^2 + bx + c) = b^2 - 4c$*;* $\operatorname{disc}(x^3 + px + q) = -4p^3 - 27q^2$*;* $\operatorname{disc}(x^3 + bx^2 + cx + d) = b^2c^2 - 4c^3 - 4b^3d - 27d^2 + 18bcd$*;* $\operatorname{disc}(x^n - a) = (-1)^{(n-1)(n-2)/2}n^n a^{n-1}$*; and for an odd prime ℓ,* $\operatorname{disc}(\Phi_\ell) = (-1)^{(\ell-1)/2}\ell^{\ell-2} = \ell^* \cdot \ell^{\ell-3}$*.*

Proof. (a) Differentiating, $f'(r_i) = a\prod_{j\neq i}(r_i - r_j)$, so

$$\prod_i f'(r_i) = a^n \prod_{i\neq j}(r_i - r_j) = a^n(-1)^{n(n-1)/2}\delta_f^2$$

(each pair $i < j$ contributes $(r_i - r_j)(r_j - r_i) = -(r_i - r_j)^2$, and there are $n(n-1)/2$ pairs). Hence $a^{2n-2}\delta_f^2 = (-1)^{n(n-1)/2}a^{n-2}\prod f'(r_i)$. It vanishes iff two roots coincide. It lies in F: if f is separable, δ_f^2 is fixed by G_f (by (b)), hence in $L^{G_f} = F$; in general $\operatorname{disc}(f)$ is the value at the coefficients of f of a universal polynomial with integer coefficients (a symmetric polynomial in the roots, expressed through the elementary symmetric functions, which are $\pm$ the coefficients divided by a; the powers of a clear the denominators), and we do not need the inseparable case. (b) σ permutes the factors $r_i - r_j$ $(i < j)$ up to sign, and the factor $r_i - r_j$ goes to $r_{\sigma(i)} - r_{\sigma(j)}$, which is $-(r_{\sigma(j)} - r_{\sigma(i)})$ exactly when σ inverts the pair; the number of inversions has the parity of $\operatorname{sgn}\sigma$. (c) As $\operatorname{char} F \neq 2$ and $\delta_f \neq 0$, $\delta_f \neq -\delta_f$. By (b), δ_f is fixed by σ iff σ is even; so $G_f \subseteq A_n$ iff $\delta_f \in F$ (fundamental theorem), iff $\operatorname{disc} f = (a^{n-1}\delta_f)^2$ is a square in F (if $\operatorname{disc} f = b^2$ with $b \in F$, then $a^{n-1}\delta_f = \pm b$). The fixed field of $G_f \cap A_n$, of index 1 or 2, contains δ_f, and equals $F(\delta_f)$ by degrees. The last formula is (b) with $\sqrt{\operatorname{disc} f} = a^{n-1}\delta_f$. (d) The roots of gh are those of g and of h; the squared differences between roots of g and roots of h contribute $\prod_{i,j}(r_i - s_j)^2$. (e) The quadratic case is $(r_1 - r_2)^2 = (r_1 + r_2)^2 - 4r_1r_2$. For $f = x^3 + px + q$, by (a) $\operatorname{disc} f = -\prod_i(3r_i^2 + p)$. With $e_1 = \sum r_i = 0$, $e_2 = p$, $e_3 = r_1r_2r_3 = -q$: $\sum r_i^2 = e_1^2 - 2e_2 = -2p$, $\sum_{i<j} r_i^2r_j^2 = e_2^2 - 2e_1e_3 = p^2$, $\prod r_i^2 = q^2$. Expanding the product of the three factors $3r_i^2 + p$ by powers of p,

$$\prod_i(3r_i^2 + p) = 27\prod_i r_i^2 + 9p\sum_{i<j} r_i^2r_j^2 + 3p^2\sum_i r_i^2 + p^3,$$

which is $27q^2 + 9p \cdot p^2 + 3p^2(-2p) + p^3 = 27q^2 + 4p^3$. For the general cubic $f = x^3 + bx^2 + cx + d$ over a field of characteristic 0, the substitution $x \mapsto x - b/3$ does not change the differences of the roots and gives $f(x - b/3) = x^3 + px + q$ with $p = c - b^2/3$ and $q = d - bc/3 + 2b^3/27$; expanding $-4p^3 - 27q^2$ gives $b^2c^2 - 4c^3 - 4b^3d - 27d^2 + 18bcd$ (a routine expansion, which we also checked by computer algebra). This proves the formula over every field of characteristic 0. For the generic monic cubic, $\prod_{i<j}(r_i - r_j)^2$ is a symmetric polynomial in the roots with integer coefficients, hence a polynomial with integer coefficients in b, c, d (the theorem on symmetric polynomials, which holds over $\mathbb{Z}$; we do not prove it, see [109, Chapter IV, Section 6]); the computation just made shows that this polynomial is $b^2c^2 - 4c^3 - 4b^3d - 27d^2 + 18bcd$ in $\mathbb{Q}[b, c, d]$, hence in $\mathbb{Z}[b, c, d]$,

and specialising gives the formula over every field, of characteristic 3 included. For $f = x^n - a$ with roots r_i: $f'(r_i) = nr_i^{n-1}$ and $\prod r_i = (-1)^{n+1}a$, so $\prod f'(r_i) = n^n(-1)^{(n+1)(n-1)}a^{n-1}$ and $\operatorname{disc} f = (-1)^{n(n-1)/2+n^2-1}n^n a^{n-1}$; the exponent differs from $(n-1)(n-2)/2$ by $n^2+n-2 = (n+2)(n-1)$, which is even. For Φ_ℓ (degree $\ell-1$, roots ζ^a, $1 \le a \le \ell-1$, $\zeta = \zeta_\ell$): differentiating $(x-1)\Phi_\ell(x) = x^\ell - 1$ at ζ^a gives $(\zeta^a - 1)\Phi'_\ell(\zeta^a) = \ell\zeta^{-a}$. Now $\prod_a \zeta^{-a} = \zeta^{-\ell(\ell-1)/2} = 1$ (ℓ odd) and $\prod_a(\zeta^a - 1) = \prod_a(1-\zeta^a) = \Phi_\ell(1) = \ell$ (an even number of sign changes), so $\prod_a \Phi'_\ell(\zeta^a) = \ell^{\ell-1}/\ell = \ell^{\ell-2}$, and $\operatorname{disc}\Phi_\ell = (-1)^{(\ell-1)(\ell-2)/2}\ell^{\ell-2} = (-1)^{(\ell-1)/2}\ell^{\ell-2}$, since $\ell-2$ is odd. □

Since $\ell^{\ell-3}$ is a square, $\operatorname{disc}(\Phi_\ell) \in \ell^*\mathbb{Q}^{\times 2}$, and (c) gives a second proof that $\sqrt{\ell^*} \in \mathbb{Q}(\zeta_\ell)$: the Galois group $(\mathbb{Z}/\ell)^\times$ of Φ_ℓ acts on the roots ζ^a by multiplication, and the sign of $x \mapsto ax$ on $(\mathbb{Z}/\ell)^\times$ is the Legendre symbol (Zolotarev's lemma). The values were also checked with PARI for $\ell \le 13$.

Proposition 5.45 (Cubics)**.** *Let* $\operatorname{char} F \neq 2$ *and* $f \in F[x]$ *a separable cubic. If* f *is irreducible,* $G_f = A_3 \simeq C_3$ *when* $\operatorname{disc} f \in F^{\times 2}$ *and* $G_f = S_3$ *otherwise. If* f *is a linear factor times an irreducible quadratic* g*,* $G_f \simeq C_2$*, with splitting field* $F(\sqrt{\operatorname{disc} g}) = F(\sqrt{\operatorname{disc} f})$*. Examples over* $\mathbb{Q}$*:* $x^3 - 2$ *has* $\operatorname{disc} = -108$ *and* $G_f = S_3$ *(Example 5.31);* $x^3 - 3x + 1$ *has* $\operatorname{disc} = 81$ *and* $G_f = C_3$*, its roots are* $2\cos(2\pi k/9)$ *for* $k = 1, 2, 4$*, and its splitting field is the real cubic subfield* $\mathbb{Q}(\zeta_9 + \zeta_9^{-1})$ *of* $\mathbb{Q}(\zeta_9)$*.*

Proof. An irreducible cubic has transitive G_f (Proposition 5.42(b)), so $G_f \in \{A_3, S_3\}$, distinguished by Proposition 5.44(c). In the reducible case L is the splitting field of g, of degree 2, and $\operatorname{disc} f = \operatorname{disc} g \cdot \operatorname{res}^2$ with $\operatorname{res} \in F^\times$ by Proposition 5.44(d) (f made monic). For $x^3 - 3x + 1$: it has no rational root (± 1 give -1 and 3), so it is irreducible; its discriminant is $-4(-3)^3 - 27 = 81 = 9^2$. With $z = \zeta_9 + \zeta_9^{-1} = 2\cos(2\pi/9)$, $z^3 = \zeta_9^3 + \zeta_9^{-3} + 3z = -1 + 3z$ (as $\zeta_3 + \zeta_3^{-1} = -1$), so z is a root; the others are its images $\zeta_9^2 + \zeta_9^{-2}$ and $\zeta_9^4 + \zeta_9^{-4}$ under σ_2 and σ_4. Hence the splitting field is $\mathbb{Q}(z)$, the fixed field of $\{\sigma_{\pm 1}\}$ in $\mathbb{Q}(\zeta_9)$, of degree $\varphi(9)/2 = 3$. □

Proposition 5.46 (Quartics)**.** *Let* $\operatorname{char} F \neq 2$ *and* $f = x^4 + ax^3 + bx^2 + cx + d \in F[x]$ *separable with roots* $r_1, \dots, r_4$*. Put* $\theta_1 = r_1r_2 + r_3r_4$*,* $\theta_2 = r_1r_3 + r_2r_4$*,* $\theta_3 = r_1r_4 + r_2r_3$*, one for each of the three partitions of the roots into two pairs, and* $R_f(y) = \prod_{i=1}^3 (y - \theta_i)$*, the* resolvent cubic*.*

(a) $R_f(y) = y^3 - by^2 + (ac - 4d)y - (a^2d - 4bd + c^2)$ *and* $\operatorname{disc} R_f = \operatorname{disc} f$*; in particular the* θ_i *are distinct.*

(b) S_4 *acts on the three partitions through a surjection* $S_4 \to S_3$ *with kernel*

$$V_4 = \{1, (12)(34), (13)(24), (14)(23)\};$$

for any separable f*,* $\theta_i \in F$ *iff* G_f *stabilises the* i*-th partition, and the degrees of the irreducible factors of* f *are the orbit sizes of* G_f*.*

(c) If f *is irreducible,* G_f *is conjugate to one of* S_4*,* A_4*,* D_4*,* C_4*,* V_4*, and:* R_f *irreducible and* $\operatorname{disc} f \notin F^{\times 2}$ *gives* S_4*;* R_f *irreducible and* $\operatorname{disc} f \in F^{\times 2}$ *gives* A_4*;* R_f *split into linear factors gives* V_4*;* R_f *with exactly one root in* F *gives* D_4 *or* C_4*, and* C_4 *iff* f *is reducible over* $F(\sqrt{\operatorname{disc} f})$ *(the criterion of Kappe and Warren [90]).*

Proof. (a) With $e_1 = -a$, $e_2 = b$, $e_3 = -c$, $e_4 = d$ the elementary symmetric functions of the roots, direct expansion gives $\theta_1 + \theta_2 + \theta_3 = e_2$, $\sum_{i<j}\theta_i\theta_j = e_1e_3 - 4e_4$ and $\theta_1\theta_2\theta_3 = e_1^2e_4 + e_3^2 - 4e_2e_4$

(each is a short computation; we also checked them by computer algebra), which is the formula. The first identity holds because each of the six products r_ir_j occurs in exactly one θ_i. For the second, $\theta_1\theta_2 = (r_1r_2 + r_3r_4)(r_1r_3 + r_2r_4) = r_1^2r_2r_3 + r_1r_2^2r_4 + r_1r_3^2r_4 + r_2r_3r_4^2$; the three products $\theta_i\theta_j$ together contain each of the twelve monomials $r_i^2r_jr_k$ ($j < k$, both different from i) exactly once, while $e_1e_3 = \sum_i r_i \cdot \sum_{j<k<m} r_jr_kr_m$ contains each of them once and $r_1r_2r_3r_4$ four times. Next $\theta_1 - \theta_2 = (r_1 - r_4)(r_2 - r_3)$, $\theta_1 - \theta_3 = (r_1 - r_3)(r_2 - r_4)$, $\theta_2 - \theta_3 = (r_1 - r_2)(r_3 - r_4)$, whose product is $\pm\delta_f$; so $\operatorname{disc} R_f = \delta_f^2 = \operatorname{disc} f$. (b) A permutation of the roots permutes the partitions; the kernel consists of the permutations preserving each partition, which is V_4, and the image has order $24/4 = 6$. By (a) the θ_i are distinct, so $\sigma \in G_f$ fixes θ_i iff it stabilises the i-th partition, and $\theta_i \in F$ iff all of G_f does. The last statement is Proposition 5.42(b). (c) G_f is transitive, so $4 \mid \#G_f$. The subgroups of S_4 of order 24, 12, 8 are S_4, A_4 (the only subgroup of index 2) and the Sylow 2-subgroups D_4 (Chapter 1); a subgroup of order 4 is cyclic, generated by a 4-cycle (transitive), or a Klein group, either the normal V_4 (transitive) or $\langle (ij), (kl) \rangle$ for disjoint transpositions (not transitive), since two commuting transpositions are disjoint. The image of G_f in S_3 is S_3, A_3, trivial for S_4, A_4, V_4, and of order 2 for D_4 and C_4 (which contain V_4, respectively $\{1, (13)(24)\}$ for $C_4 = \langle (1234) \rangle$, and stabilise one partition). By (b), R_f is irreducible iff the image is transitive on the partitions (S_4, A_4, told apart by the discriminant, $A_4 = S_4 \cap A_4$), splits iff the image is trivial (V_4), and has exactly one root iff $G_f \in \{D_4, C_4\}$. In the last case $G_f \cap A_4$ is V_4 for D_4 (transitive) and $\langle (13)(24) \rangle$ for C_4 (not transitive); by Proposition 5.44(c) and Proposition 5.42(c), $G_f \cap A_4$ is the group of f over $F(\sqrt{\operatorname{disc} f})$, so f stays irreducible there iff $G_f = D_4$. □

The next proposition is the Galois-theoretic form of the last sentence of Proposition prop:ns. Its group theory is Chapter 1: $\mathrm{GL}_2(\mathbb{F}_3)$ acts on the set $\mathbb{P}(V)$ of the four lines of $V = \mathbb{F}_3^2$, the kernel of the action is the group of scalars $\{\pm 1\}$, the induced map $\mathrm{PGL}_2(\mathbb{F}_3) \to S_4$ is an isomorphism, the sign of the permutation induced by g is $\det g \in \{\pm 1\} = \mathbb{F}_3^\times$, and the three properties of the paper (surjective determinant, no stable line, an element of determinant -1 and trace 0) leave exactly the three images $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$, $N_s(\mathbb{F}_3)$. The table below was also checked by enumerating the 55 subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$ in 16 conjugacy classes.

Proposition 5.47 (Quartics with group acting on the four lines)**.** *Let V be a two-dimensional $\mathbb{F}_3$-vector space, $\rho\colon G_F \to \mathrm{GL}(V) \simeq \mathrm{GL}_2(\mathbb{F}_3)$ a continuous homomorphism with image H, and $f \in F[x]$ a separable quartic whose root set R is in a G_F-equivariant bijection with $\mathbb{P}(V)$.*

(a) G_F acts on R through $H \to \mathrm{PGL}_2(\mathbb{F}_3) \simeq S_4$, so G_f is isomorphic to the image $\bar{H}$ of H in $\mathrm{PGL}_2(\mathbb{F}_3)$, and the splitting field of f is the fixed field of $\rho^{-1}(\{\pm 1\})$.

(b) The irreducible factors of f over F correspond to the orbits of H on the four lines, with degrees the orbit sizes.

(c) The sign of $\sigma \in G_F$ on R is $\det \rho(\sigma)$. Hence, if $\operatorname{char} F \neq 2$, $F(\sqrt{\operatorname{disc} f})$ is the field cut out by $\det \circ \rho$, and $\operatorname{disc} f \in F^{\times 2}$ iff $\det(H) = 1$.

(d) For the subgroups H with $\det(H) = \mathbb{F}_3^\times$, up to conjugacy, the orbit sizes (which by (b) are the degrees of the irreducible factors of f) and the group G_f are:

H	*label*	$\#H$	*orbits on lines*	G_f
$\mathrm{GL}_2(\mathbb{F}_3)$		48	4	S_4
$N_{ns}(\mathbb{F}_3)$	*3Nn*	16	4	D_4
$C_{ns}(\mathbb{F}_3)$	*3Cn*	8	4	C_4
$N_s(\mathbb{F}_3)$	*3Ns*	8	$2+2$	V_4, *not normal in* S_4
$B(\mathbb{F}_3)$	*3B*	12	$1+3$	S_3
two of order 6	*3B.1.1, 3B.1.2*	6	$1+3$	S_3
$C_s(\mathbb{F}_3)$	*3Cs*	4	$1+1+2$	C_2
$\langle \mathrm{diag}(1,-1)\rangle$	*3Cs.1.1*	2	$1+1+2$	C_2

So f is irreducible in the first three cases, a product of two irreducible quadratics for $N_s(\mathbb{F}_3)$, a linear factor times an irreducible cubic in the Borel cases, and two linear factors times an irreducible quadratic in the last two.

(e) If $H = N_s(\mathbb{F}_3)$, the two quadratic factors have distinct splitting fields $K_1 \neq K_2$, and the third quadratic subfield of K_1K_2 is $F(\sqrt{\mathrm{disc}\, f})$, the field cut out by $\det\circ\rho$. The resolvent cubic of f (made monic) has exactly one root in F when H is $N_s(\mathbb{F}_3)$ or $N_{ns}(\mathbb{F}_3)$, and none when $H = \mathrm{GL}_2(\mathbb{F}_3)$.

(f) If H fixes no line and contains an element of determinant -1 and trace 0, then H is conjugate to $\mathrm{GL}_2(\mathbb{F}_3)$, $N_{ns}(\mathbb{F}_3)$ or $N_s(\mathbb{F}_3)$, and f is irreducible in the first two cases and a product of two irreducible quadratics in the third.

Proof. (a) The action of σ on R corresponds to the action of $\rho(\sigma)$ on $\mathbb{P}(V)$, which depends only on the image of $\rho(\sigma)$ in $\mathrm{PGL}_2(\mathbb{F}_3)$, and $\mathrm{PGL}_2(\mathbb{F}_3)$ acts faithfully. So the kernel of $G_F \to \mathrm{Sym}(R)$ is $\rho^{-1}(\{\pm1\})$, whose fixed field is the splitting field $F(R)$ (an element of G_F fixes $F(R)$ iff it fixes every root), and $G_f \simeq G_F/\rho^{-1}(\{\pm1\}) \simeq \bar{H}$. (b) Proposition 5.42(c) with $\Omega = F^{\mathrm{sep}}$. (c) The sign of the permutation of $\mathbb{P}(V)$ induced by g is $\det g$ (Chapter 1). Apply Proposition 5.44(c). (d) The orders, orbits and images are the group theory of Chapter 1 (and our enumeration). G_f is the image $\bar{H} = H/(H \cap \{\pm1\})$; all these H contain -1 except the two groups of order 6 (which contain an element of order 3 and one of determinant -1, and meet $\{\pm1\}$ trivially) and $\langle \mathrm{diag}(1,-1)\rangle$, so $\#\bar{H} = \#H/2$ in the other cases. The transitive images of orders 24, 8, 4 are S_4, D_4 and C_4 (for $C_{ns}(\mathbb{F}_3)$, cyclic of order 8, the image is cyclic of order 4); for $N_s(\mathbb{F}_3)$ the image has order 4 with two orbits of size two, hence is $\langle (12),(34)\rangle$ for a suitable numbering, the Klein group that is not normal in S_4. The factorisations follow from (b). (e) Number the lines so that $\bar{H} = \langle (12),(34)\rangle$ and $G_f = \bar{H}$ acts on R in the same way. $K_2 = F(r_3)$, the splitting field of the factor with roots r_3, r_4, is the fixed field of the stabiliser $\langle (12)\rangle$ of r_3; likewise $K_1 = F(r_1)$ is the fixed field of $\langle (34)\rangle$. These are two of the three subgroups of order 2 of $\bar{H} \simeq V_4$, so $K_1 \neq K_2$; the third, $\langle (12)(34)\rangle = \bar{H} \cap A_4$, has fixed field $F(\sqrt{\mathrm{disc}\, f})$ by Proposition 5.44(c). By Proposition 5.46(b) the roots of R_f in F correspond to the partitions stabilised by G_f: $\langle (12),(34)\rangle$ stabilises $\{12|34\}$ and swaps the other two; D_4 stabilises exactly one partition; S_4 none. (f) The group-theoretic statement is Chapter 1; the determinant is then surjective (it takes the values 1 and -1), and (d) applies. □

In the paper 5.48. In Proposition prop:ns, $F = \mathbb{Q}$, $V = E[3]$, $\rho = \bar{\rho}_{E,3}$, and $f = \psi_3$ is the 3-division polynomial (leading coefficient 3; irreducibility is meant up to this constant). The equivariant bijection $R \leftrightarrow \mathbb{P}(E[3])$ is $\{\pm P\} \mapsto x(P)$, which is injective because $x(P) = x(Q)$ iff $Q = \pm P$

(Chapter 9). The inputs $\det\bar\rho_{E,3}=\bar\chi_3=\chi_{-3}$ (Chapter 9, Weil pairing, and Proposition 5.29) and the fact that complex conjugation has determinant -1 and trace 0 (Proposition 5.60) give the hypotheses of (f) when $E[3]$ is irreducible. Then (f) is the paper's last sentence: ψ_3 is a product of two irreducible quadratics exactly for the image $N_s(\mathbb{F}_3)$, and irreducible otherwise. By (c), $\operatorname{disc}\psi_3\in -3\cdot\mathbb{Q}^{\times 2}$ for every $E/\mathbb{Q}$; for 11a1, $\operatorname{disc}\psi_3=-3^3\cdot 11^{10}$, and for 121a1, $-3^3\cdot 11^4$. Reducible $E[3]$ always gives a rational line, hence a linear factor of ψ_3 (the patterns $1+3$ and $1+1+2$); the pattern $2+2$ of $N_s(\mathbb{F}_3)$ occurs although $E[3]$ is irreducible, because the factorisation detects the orbits of the image, not reducibility. The argument uses neither Zywina's classification nor the absence of complex multiplication. The function `ns3` of the paper's appendix returns 1 iff PARI's factorisation of `elldivpol(E,3)` has exactly two factors, the first of degree 2; as PARI lists the factors by increasing degree, the possible patterns are those of (d), and $\det\bar\rho_{E,3}$ is surjective for every $E/\mathbb{Q}$, the test returns 1 exactly when the image of $\bar\rho_{E,3}$ is $N_s(\mathbb{F}_3)$, with no hypothesis on $E[3]$.

Example 5.49 (An image $N_s(\mathbb{F}_3)$, and a surjective image)**.** Let E be 6912d1, $y^2=x^3-6x-8$ ($j=-1728$, which is not a CM j-invariant; $\Delta=-2^9\cdot 3^3$). PARI gives

$$\psi_3=3x^4-36x^2-96x-36=3(x^2-4x-2)(x^2+4x+6),$$

two irreducible quadratics with discriminants 24 and -8, so $K_1=\mathbb{Q}(\sqrt{6})$, $K_2=\mathbb{Q}(\sqrt{-2})$, and the third quadratic subfield of K_1K_2 is $\mathbb{Q}(\sqrt{-12})=\mathbb{Q}(\sqrt{-3})$, as Proposition 5.47(e) predicts; the resolvent cubic of $\psi_3/3$ is $(y-4)(y^2+16y+112)$, with exactly one rational root. Since $\det\bar\rho_{E,3}$ is surjective and only $N_s(\mathbb{F}_3)$ has the pattern $2+2$ in the table of (d), the image is $N_s(\mathbb{F}_3)$ (Sutherland's 3Ns, as in Cremona's tables). The group $N_s(\mathbb{F}_3)$ acts absolutely irreducibly on $\overline{\mathbb{F}}_3^2$: a line stable under it is an eigenline of $\operatorname{diag}(1,-1)$, hence a coordinate axis, and the antidiagonal elements swap the two axes. The image of $G_{\mathbb{Q}(\sqrt{-3})}$ is the determinant-one subgroup $\{\pm 1,\pm J\}$ (Proposition 5.66(c)), which is abelian, so $\bar\rho|_{G_{\mathbb{Q}(\sqrt{-3})}}$ is not absolutely irreducible, and $\bar\rho\simeq\bar\rho\otimes\chi_{-3}$ by Proposition 5.67. For the primes $p\neq 3$ of good reduction (here $p\geq 5$) one has $\operatorname{tr}\bar\rho_{E,3}(\operatorname{Frob}_p)\equiv a_p \pmod 3$ (Chapter 9, Chapter 11). So $a_p\equiv\chi_{-3}(\operatorname{Frob}_p)a_p \pmod 3$, and $a_p\equiv 0 \pmod 3$ whenever $\chi_{-3}(\operatorname{Frob}_p)=-1$, that is for $p\equiv 2 \pmod 3$ (Proposition 5.63(c)). This part of the example looks ahead: it uses Proposition 5.66, Proposition 5.67 and Proposition 5.63 of Section 8 and the Frobenius elements of Section 9 (Theorem 5.72); nothing in Sections 6 to 8 depends on it. Indeed $a_5=3$, $a_{11}=3$, $a_{17}=-6$, $a_{23}=6$, $a_{29}=6$, $a_{41}=6$, $a_{47}=12$, $a_{53}=-3$, $a_{59}=12$, $a_{71}=-6$; note $9\nmid a_5$. By contrast 11a1, $y^2+y=x^3-x^2-10x-20$, has

$$\psi_3=3x^4-4x^3-60x^2-237x-21,$$

irreducible, with irreducible resolvent cubic and $\operatorname{disc}\psi_3=-3^3\cdot 11^{10}\notin\mathbb{Q}^{\times 2}$: $G_{\psi_3}=S_4$ and the image of $\bar\rho_{E,3}$ is $\mathrm{GL}_2(\mathbb{F}_3)$. The paper's own example 726a1 is Exercise 5.91. The computations are reproduced in PARI/GP by:

```
E = ellinit([0,0,0,-6,-8]); f = elldivpol(E,3);
factor(f)                          \\ [x^2-4*x-2,1; x^2+4*x+6,1]
[poldisc(x^2-4*x-2), poldisc(x^2+4*x+6)]          \\ [24, -8]
[[p, ellap(E,p)] | p <- primes([5,71]), p%3 == 2]
F = elldivpol(ellinit([0,-1,1,-10,-20]),3);  \\ 11a1
[factor(F), factor(poldisc(F))]
```

5.7 Infinite Galois theory, $G_{\mathbb{Q}}$, the cyclotomic character, complex conjugation

The Galois groups of the paper are infinite: $G_{\mathbb{Q}}$ in Section 1.1 and Section 4, the decomposition and inertia groups $G_{\mathbb{Q}_q} \supseteq I_q$ in Lemmas lem:tamagawa-exp and lem:tamfactor. This section extends the fundamental theorem to infinite Galois extensions, where subgroups must be *closed* in the Krull topology, defines the absolute Galois group and the cyclotomic character χ_ℓ, proves $\chi_\ell(G_{\mathbb{Q}}) = \mathbb{Z}_\ell^\times$ (the fact that forces $\ell = 3$ in Lemma lem:h0), and studies complex conjugation, the element of $G_{\mathbb{Q}}$ that makes "irreducible" and "absolutely irreducible" coincide for $\bar\rho_{E,\ell}$. Inverse limits, profinite groups and their basic properties (open subgroups are closed of finite index, open normal subgroups form a basis at 1, continuous images of compact groups are closed) are Chapter 1. One compactness statement is used repeatedly, here and in Chapter 6, so we isolate it first.

Lemma 5.50 (Inverse limits of nonempty finite sets)**.** *Let $(I, \le)$ be a directed set (a partially ordered set in which any two elements have a common upper bound), and let $(X_i)_{i\in I}$ be nonempty finite sets with maps $f_{ij}\colon X_j \to X_i$ for $i \le j$, such that f_{ii} is the identity and $f_{ij} \circ f_{jk} = f_{ik}$ for $i \le j \le k$. Then the inverse limit*

$$\varprojlim_{i\in I} X_i = \Big\{ (x_i)_{i\in I} \in \prod_{i\in I} X_i : \ f_{ij}(x_j) = x_i \text{ for all } i \le j \Big\}$$

is nonempty.

Proof. Give each X_i the discrete topology; it is compact, being finite, so $P = \prod_i X_i$ is compact by Tychonoff's theorem (Chapter 1). For $i \le j$ the set $C_{ij} = \{x \in P : f_{ij}(x_j) = x_i\}$ is closed: it is the preimage of a subset of the finite discrete space $X_i \times X_j$ under the continuous projection $P \to X_i \times X_j$. The inverse limit is $\bigcap_{i\le j} C_{ij}$. By compactness it suffices to show that finitely many of the C_{ij}, say $C_{i_1j_1}, \dots, C_{i_rj_r}$, have a common point. As I is directed, there is $m \in I$ with $j_s \le m$ (hence $i_s \le m$) for $s = 1, \dots, r$. Choose $y \in X_m$ (it is nonempty), put $x_i = f_{im}(y)$ for every i among the i_s, j_s, and choose $x_i \in X_i$ arbitrarily for the other i. Then $f_{i_sj_s}(x_{j_s}) = f_{i_sj_s} f_{j_sm}(y) = f_{i_sm}(y) = x_{i_s}$ for each s, so x lies in all r sets. Hence $\bigcap_{i\le j} C_{ij} \neq \emptyset$. □

Finiteness matters: an inverse limit of nonempty *infinite* sets can be empty (take $X_n = \{n, n+1, n+2, \dots\}$, $n \in \mathbb{N}$, with the inclusions as maps).

Proposition 5.51 (Infinite Galois extensions)**.** *Let L/F be a Galois extension of arbitrary degree and $\mathcal{K}$ the set of finite Galois subextensions K/F of L.*

(a) $L = \bigcup_{K\in\mathcal{K}} K$; $\mathcal{K}$ is directed by inclusion (any two members lie in a third); and restriction is a group isomorphism

$$\mathrm{Gal}(L/F) \xrightarrow{\sim} \varprojlim_{K\in\mathcal{K}} \mathrm{Gal}(K/F), \qquad \sigma \mapsto (\sigma|_K)_K.$$

(b) The Krull topology *on $\mathrm{Gal}(L/F)$ is the one in which the subgroups $\mathrm{Gal}(L/K)$, $K \in \mathcal{K}$, form a basis of open neighbourhoods of 1 (and their cosets a basis of the topology). It is the inverse-limit topology transported by (a), so $\mathrm{Gal}(L/F)$ is a profinite group: compact, Hausdorff and totally disconnected. The subgroups $\mathrm{Gal}(L/M)$ with $M \subseteq L$ finite over F are open.*

(c) *The restriction maps* $\mathrm{Gal}(L/F) \to \mathrm{Gal}(K/F)$, $K \in \mathcal{K}$, *are surjective. If* L/F *is finite, the Krull topology is discrete.*

Proof. (a) For $\alpha \in L$, $m_{\alpha,F}$ is separable and splits in L (normality), so its splitting field is a member of $\mathcal{K}$ containing α. If $K_1, K_2 \in \mathcal{K}$, then $K_1K_2 \in \mathcal{K}$ (Proposition 5.24(b)). Each $\sigma \in \mathrm{Gal}(L/F)$ maps $K \in \mathcal{K}$ onto itself (Proposition 5.14(iii)), so $\sigma|_K \in \mathrm{Gal}(K/F)$, and the restrictions are compatible. The map is injective because L is the union of the K. Surjective: a compatible family (σ_K) defines a map $\sigma\colon L \to L$, $\sigma(x) = \sigma_K(x)$ for any $K \ni x$. It is well defined: if $x \in K \cap K'$, choose $K'' \in \mathcal{K}$ containing K and K'; then $\sigma_K(x) = \sigma_{K''}(x) = \sigma_{K'}(x)$ by compatibility. It is a field homomorphism over F: for $x, y \in L$ choose one K containing both, and $\sigma(x+y) = \sigma_K(x+y) = \sigma(x) + \sigma(y)$, and similarly for products. Its inverse is given by the family (σ_K^{-1}). (b) In $\varprojlim \mathrm{Gal}(K/F)$ with the topology induced by the product of discrete groups, a basis of neighbourhoods of 1 is given by the kernels of the projections to finitely many factors $\mathrm{Gal}(K_1/F), \dots, \mathrm{Gal}(K_r/F)$; under (a) such a kernel is $\mathrm{Gal}(L/K_1 \cdots K_r)$, and $K_1 \cdots K_r \in \mathcal{K}$. So the two topologies agree, and the inverse limit of finite groups is profinite (Chapter 1). If M/F is finite, its normal closure M' in L is in $\mathcal{K}$ (Proposition 5.14), and $\mathrm{Gal}(L/M) \supseteq \mathrm{Gal}(L/M')$ is a union of cosets of an open subgroup. (c) Let $K_0 \in \mathcal{K}$ and $\tau \in \mathrm{Gal}(K_0/F)$. The set $\mathcal{K}_0$ of $K \in \mathcal{K}$ containing K_0 is directed by inclusion (by (a)). For $K \in \mathcal{K}_0$ the set X_K of $\sigma \in \mathrm{Gal}(K/F)$ with $\sigma|_{K_0} = \tau$ is finite and nonempty (Theorem 5.23(d)), and for $K' \subseteq K''$ in $\mathcal{K}_0$ restriction maps $X_{K''}$ to $X_{K'}$, compatibly with composition. By Lemma 5.50 there is a compatible family $(\sigma_K)_{K \in \mathcal{K}_0}$. Every $K \in \mathcal{K}$ lies in $KK_0 \in \mathcal{K}_0$, so the members of $\mathcal{K}_0$ exhaust L, and the family defines as in (a) an element $\sigma \in \mathrm{Gal}(L/F)$, with $\sigma|_{K_0} = \tau$. (Alternatively, extend τ to an F-embedding $L \to \overline{\mathbb{F}}$ by Theorem 5.10(b); its image is L by normality.) For L/F finite, $\{1\} = \mathrm{Gal}(L/L)$ is open. □

Theorem 5.52 (Krull's fundamental theorem)**.** *Let* L/F *be Galois with group* $G = \mathrm{Gal}(L/F)$ *in the Krull topology.*

(a) *For every intermediate field* M, L/M *is Galois,* $\mathrm{Gal}(L/M)$ *is a closed subgroup of* G, *and* $L^{\mathrm{Gal}(L/M)} = M$.

(b) *For every subgroup* $H \leq G$, $\mathrm{Gal}(L/L^H) = \overline{H}$, *the closure of* H.

(c) *Hence* $H \mapsto L^H$ *and* $M \mapsto \mathrm{Gal}(L/M)$ *are mutually inverse inclusion-reversing bijections between the* closed *subgroups of* G *and the intermediate fields.*

(d) *Open subgroups correspond to the intermediate fields* M *finite over* F, *and then* $[G : \mathrm{Gal}(L/M)] = [M : F]$.

(e) M/F *is Galois iff* $\mathrm{Gal}(L/M)$ *is normal in* G; *then restriction induces an isomorphism of topological groups* $G/\mathrm{Gal}(L/M) \simeq \mathrm{Gal}(M/F)$ *(quotient topology on the left, Krull topology on the right).*

(f) $\mathrm{Gal}(L/\sigma M) = \sigma\,\mathrm{Gal}(L/M)\sigma^{-1}$ *for* $\sigma \in G$.

Proof. (a) L/M is separable, and normal by Proposition 5.14. For $x \in L$, the stabiliser of x in G contains the open subgroup $\mathrm{Gal}(L/K)$ for any $K \in \mathcal{K}$ containing x, so it is open, hence closed; $\mathrm{Gal}(L/M)$ is the intersection of the stabilisers of the $x \in M$, hence closed. If $x \in L \setminus M$, then $m_{x,M}$ has degree > 1, is separable and splits in L, so it has a root $y \neq x$ in L. Let $K \subseteq L$ be the splitting field of $m_{x,M}$ over M, finite Galois over M; by Proposition 5.42(b) some $\tau \in \mathrm{Gal}(K/M)$ has $\tau(x) = y$, and by Proposition 5.51(c), applied to L/M, τ extends to an

element of $\mathrm{Gal}(L/M)$, which moves x. So $L^{\mathrm{Gal}(L/M)} = M$. (b) $H \subseteq \mathrm{Gal}(L/L^H)$, which is closed by (a), so $\overline{H} \subseteq \mathrm{Gal}(L/L^H)$. Conversely, let $\sigma \in \mathrm{Gal}(L/L^H)$ and let $\sigma\,\mathrm{Gal}(L/K)$, $K \in \mathcal{K}$, be a basic neighbourhood of σ. Let $H_K \leq \mathrm{Gal}(K/F)$ be the image of H under restriction. Its fixed field in K is $K \cap L^H$ (an element $x \in K$ satisfies $h|_K(x) = h(x)$, so it is fixed by H_K iff it is fixed by H), which σ fixes; so $\sigma|_K \in \mathrm{Gal}(K/K^{H_K}) = H_K$ by the finite fundamental theorem. Thus some $h \in H$ has $h|_K = \sigma|_K$, that is $h \in \sigma\,\mathrm{Gal}(L/K)$. Every neighbourhood of σ meets H, so $\sigma \in \overline{H}$. (c) follows from (a) and (b). (d) If $[M : F] < \infty$, $\mathrm{Gal}(L/M)$ is open (Proposition 5.51(b)). If $\mathrm{Gal}(L/M)$ is open, it contains some $\mathrm{Gal}(L/K)$, $K \in \mathcal{K}$, so $M \subseteq K$ is finite over F. Then $\mathrm{Gal}(L/M)$ is the preimage of $\mathrm{Gal}(K/M)$ under the surjection $G \to \mathrm{Gal}(K/F)$, and its index is $[\mathrm{Gal}(K/F) : \mathrm{Gal}(K/M)] = [M : F]$. (e) and (f). (f) is immediate. As in the finite case, every F-embedding $M \to \overline{\mathbb{F}}$ extends to one of L (Theorem 5.10(b)), which lies in G, so M/F is normal iff $\sigma M = M$ for all $\sigma \in G$, iff $\mathrm{Gal}(L/M)$ is normal by (f) and (c). Then restriction $G \to \mathrm{Gal}(M/F)$ is a homomorphism, surjective (extension of automorphisms), with kernel $\mathrm{Gal}(L/M)$. It is continuous: the preimage of a basic open subgroup $\mathrm{Gal}(M/K)$ ($K \subseteq M$ finite Galois over F) is $\mathrm{Gal}(L/K)$, open. The induced bijection $G/\,\mathrm{Gal}(L/M) \to \mathrm{Gal}(M/F)$ is continuous from a compact space to a Hausdorff space, hence a homeomorphism. □

Definition 5.53 (The absolute Galois group)**.** The *absolute Galois group* of F is $G_F = \mathrm{Gal}(F^{\mathrm{sep}}/F)$ with the Krull topology (Proposition 5.18). For $K \subseteq F^{\mathrm{sep}}$, $G_K = \mathrm{Gal}(F^{\mathrm{sep}}/K) \subseteq G_F$. In particular $G_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$. A homomorphism from G_F *cuts out* the fixed field of its kernel when the kernel is closed.

Proposition 5.54 (The absolute Galois group)**.** *(a) For K/F finite inside F^{sep}, G_K is an open subgroup of G_F of index $[K : F]$; every open subgroup is of this form; $\sigma G_K \sigma^{-1} = G_{\sigma K}$; and G_K is normal iff K/F is Galois, in which case $G_F/G_K \simeq \mathrm{Gal}(K/F)$.*

(b) $G_{\mathbb{F}_q} = \mathrm{Gal}(\overline{\mathbb{F}}_q/\mathbb{F}_q) \simeq \widehat{\mathbb{Z}} = \varprojlim \mathbb{Z}/n$, by an isomorphism sending Frob_q to 1; Frob_q generates a dense subgroup, and the open subgroups are the $n\widehat{\mathbb{Z}} = G_{\mathbb{F}_{q^n}}$, $n \geq 1$.

(c) For a number field $K \subseteq \overline{\mathbb{Q}}$, G_K is open of index $[K : \mathbb{Q}]$ in $G_{\mathbb{Q}}$. So $G_{\mathbb{Q}(\sqrt{d})}$ has index 2 for d not a square, and $G_{\mathbb{Q}(\zeta_n)}$ is open and normal of index $\varphi(n)$, with $G_{\mathbb{Q}}/G_{\mathbb{Q}(\zeta_n)} \simeq (\mathbb{Z}/n)^\times$.

(d) $G_{\mathbb{Q}}$ is uncountable and non-abelian. Its maximal abelian quotient is $\mathrm{Gal}(\mathbb{Q}^{\mathrm{ab}}/\mathbb{Q}) \simeq \widehat{\mathbb{Z}}^\times$, where $\mathbb{Q}^{\mathrm{ab}} = \mathbb{Q}(\mu_\infty)$ is the union of the cyclotomic fields (the Kronecker-Weber theorem).

Proof of (a) to (c), and of the first sentence of (d). (a) is Theorem 5.52(d), (e), (f) with $L = F^{\mathrm{sep}}$. (b) Every finite extension of $\mathbb{F}_q$ in $\overline{\mathbb{F}}_q$ is an $\mathbb{F}_{q^n}$, Galois with group $\mathbb{Z}/n$ generated by Frob_q (Theorem 5.25); $\mathbb{F}_{q^m} \subseteq \mathbb{F}_{q^n}$ iff $m \mid n$, with restriction $\mathbb{Z}/n \to \mathbb{Z}/m$ the reduction. By Proposition 5.51(a), $G_{\mathbb{F}_q} \simeq \varprojlim_n \mathbb{Z}/n$ (divisibility order), which is $\widehat{\mathbb{Z}}$ of Chapter 1 (the factorials are cofinal), with $\mathrm{Frob}_q \mapsto (1 \bmod n)_n = 1$. The image of $\langle \mathrm{Frob}_q \rangle$ in every finite quotient is everything, so it is dense. The open subgroups are the $G_{\mathbb{F}_{q^n}}$ by (a), and $G_{\mathbb{F}_{q^n}}$ is the kernel of $\widehat{\mathbb{Z}} \to \mathbb{Z}/n$, which is $n\widehat{\mathbb{Z}}$. (c) is (a) with $F = \mathbb{Q}$, and Theorem 5.28. (d) By (c) and Proposition 5.27(c), $G_{\mathbb{Q}}$ has infinitely many distinct subgroups of index 2; a profinite group with infinitely many open subgroups is infinite, and an infinite profinite group is uncountable (it is a compact Hausdorff space without isolated points, the open subgroups having finite index). It is non-abelian since $\mathrm{Gal}(\mathbb{Q}(2^{1/3}, \zeta_3)/\mathbb{Q}) \simeq S_3$ is a quotient (Example 5.31). The rest of (d) is the Kronecker-Weber theorem, which we do not prove; see Chapter 6 and [201, Chapter 14]. □

Example 5.55 (Two warnings)**.** (1) The subgroup $\mathrm{Frob}_p^{\mathbb{Z}}$ of $G_{\mathbb{F}_p} \simeq \widehat{\mathbb{Z}}$ is dense and not closed: it is countable, while $\widehat{\mathbb{Z}}$ is uncountable. Its fixed field is $\mathbb{F}_p$, the same as that of $G_{\mathbb{F}_p}$; this is why Theorem 5.52(c) requires closed subgroups. (2) A subgroup of finite index need not be open. Let $L = \mathbb{Q}(\sqrt{-1}, \sqrt{2}, \sqrt{3}, \sqrt{5}, \sqrt{7}, \dots)$, the compositum of all quadratic fields. The fields $\mathbb{Q}(\Delta^{1/2})$ with $\Delta/\mathbb{Q}^{\times 2}$ finite are finite Galois and cofinal among the finite subextensions of L (each of these lies in a compositum of finitely many quadratic fields), and $\mathrm{Gal}(\mathbb{Q}(\Delta^{1/2})/\mathbb{Q}) \simeq \mathrm{Hom}(\Delta/\mathbb{Q}^{\times 2}, \{\pm 1\})$ compatibly with restriction (Theorem 5.37(a) with $n = 2$). Passing to the limit (Proposition 5.51(a), where the limit may be taken over this cofinal family) gives $\mathrm{Gal}(L/\mathbb{Q}) \simeq \varprojlim_{\Delta} \mathrm{Hom}(\Delta/\mathbb{Q}^{\times 2}, \{\pm 1\}) = \mathrm{Hom}(\mathbb{Q}^{\times}/\mathbb{Q}^{\times 2}, \{\pm 1\}) \simeq \prod_{\mathbb{N}} \mathbb{Z}/2$, as $\mathbb{Q}^{\times}/\mathbb{Q}^{\times 2}$ is the union of the $\Delta/\mathbb{Q}^{\times 2}$ and is an $\mathbb{F}_2$-vector space with basis -1 and the primes. The open subgroups of index 2 are the kernels of the countably many continuous characters, which are the evaluations at the elements of $\mathbb{Q}^{\times}/\mathbb{Q}^{\times 2}$; but $\prod_{\mathbb{N}} \mathbb{Z}/2$ has uncountably many subgroups of index 2 (kernels of linear forms on an $\mathbb{F}_2$-vector space of uncountable dimension, whose existence uses the axiom of choice), so most are not open. We do not use this.

Corollary 5.56 (Absolute Kummer theory)**.** *Let* $\mathrm{char}\, F \nmid n$ *and* $\mu_n \subset F$*. Then* $a \mapsto \chi_a$*,* $\chi_a(\sigma) = \sigma(\alpha)/\alpha$ *(*$\alpha^n = a$*), is an isomorphism*

$$F^{\times}/F^{\times n} \xrightarrow{\sim} \mathrm{Hom}_{\mathrm{cont}}(G_F, \mu_n),$$

μ_n being discrete. After a primitive ζ_n is chosen (so $\mu_n \simeq \mathbb{Z}/n$), the surjective continuous homomorphisms $G_F \to \mathbb{Z}/n$ correspond to the elements of exact order n of $F^{\times}/F^{\times n}$. For $n = 2$ and $\mathrm{char}\, F \neq 2$*: $F^{\times}/F^{\times 2} \simeq \mathrm{Hom}_{\mathrm{cont}}(G_F, \{\pm 1\})$, the class of d corresponding to the character of $F(\sqrt{d})$.*

Proof. χ_a is continuous: its kernel $G_{F(\alpha)}$ is open. It is a homomorphism in a and injective modulo $F^{\times n}$ by Proposition 5.35(b) with $L = F^{\mathrm{sep}}$. Surjective: a continuous $\chi\colon G_F \to \mu_n$ has open kernel G_K, K/F finite Galois with group a subgroup of μ_n, abelian of exponent dividing n. By Theorem 5.37(b), $K = F_{\Delta}$ with $\Delta/F^{\times n}$ finite, and by (a) of that theorem the character of $\mathrm{Gal}(K/F)$ induced by χ is $\sigma \mapsto \sigma(\alpha)/\alpha$ for some $a = \alpha^n \in \Delta$; so $\chi = \chi_a$. The surjective homomorphisms are those of order n in the group $\mathrm{Hom}_{\mathrm{cont}}(G_F, \mu_n)$, which correspond to the elements of order n. For $n = 2$, $\mu_2 = \{\pm 1\} \subset F$ always, and $\chi_d(\sigma) = \sigma(\sqrt{d})/\sqrt{d}$. □

Corollary 5.57 (Translation, infinite case)**.** *Let L/F be Galois (of any degree) and M/F any extension, inside a common field. Then LM/M is Galois and restriction* $\mathrm{Gal}(LM/M) \to \mathrm{Gal}(L/L \cap M)$ *is an isomorphism of topological groups. In particular, for K/F finite separable and $L \subseteq F^{\mathrm{sep}}$ Galois over F,* $\mathrm{Gal}(LK/K) \simeq \mathrm{Gal}(L/L \cap K)$*.*

Proof. LM is generated over M by roots of separable polynomials over F that split in L, so LM/M is normal and separable. Restriction is a continuous homomorphism $\mathrm{Gal}(LM/M) \to \mathrm{Gal}(L/F)$ (the preimage of $\mathrm{Gal}(L/K)$ is $\mathrm{Gal}(LM/MK)$), injective as before. Its image H is compact, hence closed, and as in Proposition 5.24 $L^H = L \cap M$; by Theorem 5.52(c), $H = \mathrm{Gal}(L/L \cap M)$. A continuous bijection from a compact space to a Hausdorff space is a homeomorphism. □

Definition 5.58 (The cyclotomic character)**.** Let ℓ be a prime and F a field of characteristic $\neq \ell$. For $k \geq 1$ the group $\mu_{\ell^k} = \mu_{\ell^k}(F^{\mathrm{sep}})$ is cyclic of order ℓ^k ($x^{\ell^k} - 1$ is separable), and G_F acts on it by automorphisms, $\sigma(\zeta) = \zeta^{a_k(\sigma)}$ with $a_k(\sigma) \in (\mathbb{Z}/\ell^k)^{\times}$. The *$\ell$-adic cyclotomic character* is

$$\chi_\ell\colon G_F \to \mathbb{Z}_\ell^{\times} = \varprojlim_k (\mathbb{Z}/\ell^k)^{\times}, \qquad \chi_\ell(\sigma) = (a_k(\sigma))_k,$$

so that $\sigma(\zeta) = \zeta^{\chi_\ell(\sigma)}$ for every $\zeta \in \mu_{\ell^\infty} = \bigcup_k \mu_{\ell^k}$; $\bar\chi_\ell = \chi_\ell \bmod \ell \colon G_F \to \mathbb{F}_\ell^\times$. The *Tate module of* μ is $\mathbb{Z}_\ell(1) = \varprojlim_k \mu_{\ell^k}$ (transition maps $\zeta \mapsto \zeta^\ell$), and for a $\mathbb{Z}_\ell$-module M with G_F-action, $M(1) = M \otimes_{\mathbb{Z}_\ell} \mathbb{Z}_\ell(1)$.

Proposition 5.59 (The cyclotomic character)**.** *(a) χ_ℓ is a well defined continuous homomorphism, and it is the unique map $G_F \to \mathbb{Z}_\ell^\times$ with $\sigma(\zeta) = \zeta^{\chi_\ell(\sigma)}$ on μ_{ℓ^∞}. $\chi_\ell \bmod \ell^k$ is trivial iff $\mu_{\ell^k} \subset F$, and $\ker \chi_\ell = G_{F(\mu_{\ell^\infty})}$.*

(b) For $F = \mathbb{Q}$: χ_ℓ is surjective, and $\mathrm{Gal}(\mathbb{Q}(\mu_{\ell^\infty})/\mathbb{Q}) \simeq \mathbb{Z}_\ell^\times$ as topological groups; $\chi_\ell(\sigma) \bmod \ell^k$ is the a with $\sigma|_{\mathbb{Q}(\zeta_{\ell^k})} = \sigma_a$.

(c) For $F = \mathbb{Q}$: $\bar\chi_\ell$ is surjective onto $\mathbb{F}_\ell^\times$ with kernel $G_{\mathbb{Q}(\zeta_\ell)}$, and for odd ℓ, $\chi_{\ell^*} = \left(\frac{\bar\chi_\ell}{\ell}\right) = \bar\chi_\ell^{(\ell-1)/2}$ (Proposition 5.29).

(d) For $F = \mathbb{F}_q$ with $\ell \nmid q$: $\chi_\ell(\mathrm{Frob}_q) = q$.

(e) $\mathbb{Z}_\ell(1)$ is a free $\mathbb{Z}_\ell$-module of rank one, on which $\sigma \in G_F$ acts by multiplication by $\chi_\ell(\sigma)$; $\mathbb{Z}_\ell(1)/\ell^k\mathbb{Z}_\ell(1) \simeq \mu_{\ell^k}$, by projection to the k-th component.

Proof. (a) If $\zeta \in \mu_{\ell^{k+1}}$ then $\zeta^\ell \in \mu_{\ell^k}$ and $\sigma(\zeta^\ell) = \zeta^{\ell a_{k+1}(\sigma)}$, so $a_{k+1}(\sigma) \equiv a_k(\sigma) \pmod{\ell^k}$: the $a_k(\sigma)$ form an element of $\mathbb{Z}_\ell^\times$. Each a_k is multiplicative in σ and constant on cosets of the open subgroup $G_{F(\mu_{\ell^k})}$; as the subgroups $1 + \ell^k\mathbb{Z}_\ell$ form a basis of neighbourhoods of 1 in $\mathbb{Z}_\ell^\times$, χ_ℓ is continuous. Uniqueness is clear, and the statements on kernels are the definitions. (b) By Theorem 5.28, $G_\mathbb{Q} \to \mathrm{Gal}(\mathbb{Q}(\zeta_{\ell^k})/\mathbb{Q}) \simeq (\mathbb{Z}/\ell^k)^\times$ is surjective for each k, and this composite is $\chi_\ell \bmod \ell^k$. So $\chi_\ell(G_\mathbb{Q})$ is dense in $\mathbb{Z}_\ell^\times$; being compact, it is closed, hence equal to $\mathbb{Z}_\ell^\times$. By Theorem 5.52(e), $\mathrm{Gal}(\mathbb{Q}(\mu_{\ell^\infty})/\mathbb{Q}) \simeq G_\mathbb{Q}/\ker\chi_\ell \simeq \mathbb{Z}_\ell^\times$, topologically (continuous bijection of compact Hausdorff groups). (c) The case $k = 1$ of (b), and Proposition 5.29(b). (d) $\mathrm{Frob}_q(\zeta) = \zeta^q$. (e) Choose ζ_{ℓ^k} inductively: ζ_ℓ a generator of μ_ℓ, and $\zeta_{\ell^{k+1}}$ an ℓ-th root of ζ_{ℓ^k}, which has order ℓ^{k+1}. Then $a \mapsto (\zeta_{\ell^k}^a)_k$ is an isomorphism $\mathbb{Z}_\ell \to \mathbb{Z}_\ell(1)$ (its components $\mathbb{Z}/\ell^k \to \mu_{\ell^k}$ are isomorphisms), and $\sigma(\zeta_{\ell^k}^a) = \zeta_{\ell^k}^{a\chi_\ell(\sigma)}$. The kernel of the projection to μ_{ℓ^k} corresponds to $\ell^k\mathbb{Z}_\ell$. □

In the additive notation of Convention 5.3(c), $\sigma \cdot z = \chi_\ell(\sigma)z$ for $z \in \mathbb{Z}_\ell(1)$; so Frob_q acts on $\mathbb{Z}_\ell(1)$ by q, which is the statement "Frob acts on $\mathbb{Z}_\ell(1)$ by q" in the proof of Lemma lem:tamfactor (with $F = \mathbb{Q}_q$ and Frob acting through the residue field, Chapter 7).

The module $\mathbb{Z}_\ell(1)$ is isomorphic to $\mathbb{Z}_\ell$ as a $\mathbb{Z}_\ell$-module, but only after a compatible system of roots of unity has been chosen, and never as a G_F-module (unless χ_ℓ is trivial): G_F acts trivially on $\mathbb{Z}_\ell$ and through χ_ℓ on $\mathbb{Z}_\ell(1)$. Over $\mathbb{Q}$, for instance, complex conjugation acts on $\mathbb{Z}_\ell(1)$ by -1 (Proposition 5.60(b)) and an arithmetic Frobenius at $p \neq \ell$ by p (Theorem 5.72(c)). This is the whole content of the "(1)" in the paper's $T(1)$ and $\mathrm{ad}^0 T(1)$: the twist changes the Galois action, not the underlying module.

Proposition 5.60 (Complex conjugation)**.** *Let $c \in G_\mathbb{Q}$ be the restriction to $\overline{\mathbb{Q}}$ of complex conjugation (Convention 5.1).*

(a) c is an element of order 2. Every embedding $\overline{\mathbb{Q}} \to \mathbb{C}$ is $\iota \circ \sigma$ with ι the inclusion and $\sigma \in G_\mathbb{Q}$, and complex conjugation transported by it is $\sigma^{-1}c\sigma$. A complex conjugation *is an element of the conjugacy class of c.*

(b) $\chi_\ell(c) = -1$ for every ℓ; $\chi_d(c) = -1$ iff $d < 0$. So $\chi_{\ell^*}(c) = (-1)^{(\ell-1)/2}$ and $\chi_{-3}(c) = \chi_{-4}(c) = -1$.

(c) *(Artin and Schreier.) Every element of $G_{\mathbb{Q}}$ of finite order other than 1 is a complex conjugation; in particular it has order 2.*

(d) *Let k be a field with $\operatorname{char} k \neq 2$ and $\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(k)$ a homomorphism with $\det\rho(c) = -1$ (for instance $\det\rho = \bar{\chi}_\ell$ with ℓ odd, or $\det\rho = \chi_\ell$). Then $\rho(c)$ is conjugate to $\mathrm{diag}(1,-1)$, so it has determinant -1 and trace 0, and ρ is irreducible over k iff it is absolutely irreducible.*

Proof. (a) The conjugate of an algebraic number is algebraic (it is a root of the same polynomial with rational coefficients), so complex conjugation maps $\overline{\mathbb{Q}}$ to itself; it has order 2 because $c(i) = -i$. An embedding $\tau\colon \overline{\mathbb{Q}} \to \mathbb{C}$ has image algebraic over $\mathbb{Q}$, so contained in $\overline{\mathbb{Q}}$, and equal to it ($\overline{\mathbb{Q}}/\tau(\overline{\mathbb{Q}})$ is algebraic and $\tau(\overline{\mathbb{Q}})$ is algebraically closed); so $\tau = \iota\circ\sigma$ with $\sigma \in G_{\mathbb{Q}}$, and $x \mapsto \tau^{-1}(\tau(x))$ is $\sigma^{-1}c\sigma$. (b) For $\zeta \in \mu_{\ell^\infty} \subset \mathbb{C}$, $c(\zeta) = \bar{\zeta} = \zeta^{-1}$. If $d > 0$, $\sqrt{d}$ is real and fixed; if $d < 0$, $\sqrt{d}$ is purely imaginary and $c(\sqrt{d}) = -\sqrt{d}$. Apply to ℓ^*, -3, -4. (d) $\rho(c)^2 = 1$, so the minimal polynomial of $\rho(c)$ divides $X^2 - 1 = (X-1)(X+1)$, which has distinct roots as $\operatorname{char} k \neq 2$; hence $\rho(c)$ is diagonalisable with eigenvalues in $\{\pm 1\}$, and $\det\rho(c) = -1$ forces the eigenvalues 1 and -1. The equivalence is the case $n = 2$ of the distinct-eigenvalue criterion of Chapter 4: a line of $\bar{k}^2$ stable under $\rho(G_{\mathbb{Q}})$ is an eigenline of $\rho(c)$, and both eigenlines are defined over k. For $\det\rho = \bar{\chi}_\ell$, $\bar{\chi}_\ell(c) = -1 \neq 1$ in $\mathbb{F}_\ell$ as ℓ is odd. □

We do not prove (c). It follows from the theorem of Artin and Schreier that a field K with $[\bar{K} : K]$ finite and greater than 1 has characteristic 0 and $\bar{K} = K(i)$ ([109, Chapter VI, Section 9]), together with the theory of real closed fields ([109, Chapter XI]), which shows that such a K is real closed; both locations are pointers we have not re-verified. It is not used in the paper; what is used, in Proposition prop:ns and Lemmas lem:h0, lem:old and lem:dfg21, is (d) and the fact that $\mathrm{Gal}(\mathbb{C}/\mathbb{R}) = \{1, c\}$ has order 2 (so $H^1(\mathbb{R}, M)$ is killed by 2, Chapter 17).

5.8 Continuous representations of profinite groups

The paper's objects are continuous representations of $G_{\mathbb{Q}}$ and of its local subgroups: $\rho = \rho_{E,\ell}\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{Z}_\ell)$ on $T = T_\ell E$, its reductions $\rho \bmod \ell^k$ and $\bar{\rho}$, and the characters χ_ℓ, χ_d, ε. This section translates the representation theory of Chapter 4 (which is about abstract groups) to profinite groups: what continuity means, the field cut out by a representation, twists, restriction to an open subgroup such as $G_{\mathbb{Q}(\sqrt{\ell^*})}$ (the hypothesis of Theorem thm:main), the index-two criterion used in Lemma lem:h0 and Proposition prop:ns, independence of $\bar{\rho}^{ss}$ from the lattice (Lemma lem:old), and the ℓ-adic Kummer cocycle (Lemma lem:tamfactor).

Definition 5.61 (Continuous representations)**.** Let G be a profinite group. A finite field, $\overline{\mathbb{F}}_\ell$, or any field regarded as discrete, gives $\mathrm{GL}_n(k)$ the discrete topology. A finite extension E_λ of $\mathbb{Q}_\ell$, with ring of integers $\mathcal{O}$ and uniformiser ϖ (Chapter 7), gives $\mathrm{GL}_n(E_\lambda) \subseteq E_\lambda^{n^2}$ the subspace topology of the ℓ-adic topology; the subgroups $1 + \varpi^m \mathrm{M}_n(\mathcal{O})$, $m \geq 1$, form a basis of neighbourhoods of 1, and $\mathrm{GL}_n(\mathcal{O})$ is an open subgroup. A *representation* of G is a continuous homomorphism $\rho\colon G \to \mathrm{GL}_n(k)$ for such a k, or $\rho\colon G \to \mathrm{GL}_n(\mathcal{O})$. For $G = G_F$, the field *cut out* by ρ is $F_\rho = (F^{\mathrm{sep}})^{\ker\rho}$; ρ *factors through* $\mathrm{Gal}(F_\rho/F)$.

Proposition 5.62 (Continuous representations)**.** *Let G be profinite.*

(a) *If k is discrete, a homomorphism $\rho\colon G \to \mathrm{GL}_n(k)$ is continuous iff $\ker\rho$ is open, iff ρ factors through a finite quotient G/U, U open normal; then $\rho(G)$ is finite. For $G = G_F$, F_ρ/F is then finite Galois and $\mathrm{Gal}(F_\rho/F) \simeq \rho(G_F)$. In particular a representation of a finite quotient of G is, by inflation, a representation of G.*

(b) *A homomorphism* $\rho\colon G \to \mathrm{GL}_n(\mathcal{O})$ *is continuous iff every* $\rho \bmod \varpi^m$ *is. Then* $\rho(G)$ *is compact, hence closed,* $\ker\rho$ *is a closed normal subgroup, and for* $G = G_F$, F_ρ/F *is Galois (in general infinite) with* $\mathrm{Gal}(F_\rho/F) \simeq \rho(G_F)$ *as topological groups.*

(c) *Every continuous* $\rho\colon G \to \mathrm{GL}_n(E_\lambda)$ *stabilises an* $\mathcal{O}$*-lattice* $\Lambda \subset E_\lambda^n$ *(a free* $\mathcal{O}$*-submodule of rank* n *spanning* E_λ^n*); in a basis of* Λ, ρ *is a continuous* $\rho\colon G \to \mathrm{GL}_n(\mathcal{O})$*, and its reduction* $\bar\rho_\Lambda$ *on* $\Lambda/\varpi\Lambda$ *is continuous.*

(d) *Every continuous* $\rho\colon G \to \mathrm{GL}_n(\mathbb{C})$ *has finite image. In particular continuous characters* $G_\mathbb{Q} \to \mathbb{C}^\times$ *have finite order.*

(e) *Subrepresentations, quotients, direct sums, tensor products, duals,* Hom *and* ad^0 *of continuous representations, the semisimplification* ρ^{ss}*, and twists* $\rho \otimes \chi$ *by continuous characters are continuous.*

Proof. (a) $\{1\}$ is open in $\mathrm{GL}_n(k)$, so continuity implies $\ker\rho$ open; conversely if $\ker\rho$ is open, the preimage of any set is a union of cosets of $\ker\rho$, hence open. An open subgroup has finite index and contains an open normal subgroup (Chapter 1), and $\ker\rho$ is itself normal. The statement about F_ρ is Theorem 5.52(d), (e) with the open normal subgroup $\ker\rho$. For inflation: $\rho' \circ \pi$ with $\pi\colon G \to G/U$ has open kernel. (b) A homomorphism of topological groups is continuous iff it is continuous at 1, and $\rho^{-1}(1 + \varpi^m \mathrm{M}_n(\mathcal{O})) = \ker(\rho \bmod \varpi^m)$. The image of a compact group is compact; the kernel is the intersection of the closed subgroups $\ker(\rho \bmod \varpi^m)$. Then Theorem 5.52(e) gives $\mathrm{Gal}(F_\rho/F) \simeq G_F/\ker\rho$, and the continuous bijection $G_F/\ker\rho \to \rho(G_F)$ is a homeomorphism (compact to Hausdorff). (c) $\mathrm{GL}_n(\mathcal{O})$ is open in $\mathrm{GL}_n(E_\lambda)$, so $U = \rho^{-1}(\mathrm{GL}_n(\mathcal{O}))$, the stabiliser of $\mathcal{O}^n$, is an open subgroup, of finite index. Put $\Lambda = \sum_{gU \in G/U} \rho(g)\mathcal{O}^n$, a finite sum (well defined since $\rho(u)\mathcal{O}^n = \mathcal{O}^n$ for $u \in U$). It is a finitely generated $\mathcal{O}$-submodule of E_λ^n containing $\mathcal{O}^n$ and stable under G; finitely generated and torsion-free over the principal ideal domain $\mathcal{O}$, it is free (Chapter 3), of rank n as it contains $\mathcal{O}^n$ and lies in $\varpi^{-m}\mathcal{O}^n$ for some m (the finitely many matrices $\rho(g)$, $gU \in G/U$, have entries with bounded denominators: choose m with $\varpi^m\rho(g) \in \mathrm{M}_n(\mathcal{O})$ for all of them). In a basis of Λ the matrices $\rho(g)$ lie in $\mathrm{GL}_n(\mathcal{O})$, and continuity is unchanged by the change of basis. The reduction is continuous by (b) and (a). (d) Let $\|\cdot\|$ be the operator norm and $W = \{A \in \mathrm{GL}_n(\mathbb{C}) : \|A - 1\| < 1\}$. We claim that W contains no subgroup other than $\{1\}$. Let A generate a subgroup inside W. For an eigenvalue ν of A and every $k \in \mathbb{Z}$, $\nu^k - 1$ is an eigenvalue of $A^k - 1$, so $|\nu^k - 1| \le \|A^k - 1\| < 1$. Then $|\nu| = 1$ (otherwise $|\nu^k|$ is unbounded for $k \to \infty$ or $k \to -\infty$), and all powers of ν lie on the arc $|z - 1| < 1$ of the unit circle, that is in $\{e^{i\theta} : |\theta| < \pi/3\}$; if $\nu = e^{i\theta} \ne 1$ with $0 < |\theta| < \pi/3$, some multiple $k\theta$ lies in $[\pi/3, \pi]$ modulo 2π, a contradiction. So all eigenvalues are 1 and $A = 1 + N$ with N nilpotent. If $N \ne 0$, let $m \ge 1$ be maximal with $N^m \ne 0$; then $A^k - 1 = \sum_{j=1}^m \binom{k}{j} N^j$, and as $k \to \infty$ the coefficient $\binom{k}{m}$ dominates, so $\|A^k - 1\| \to \infty$ (compare $\|\cdot\|$ with the norm of the coefficients in the basis $N, \dots, N^m$ of their span), a contradiction. Hence $A = 1$, proving the claim. Now $\rho^{-1}(W)$ is an open neighbourhood of 1, so it contains an open normal subgroup U (Chapter 1); $\rho(U)$ is a subgroup inside W, so $\rho(U) = 1$ and ρ factors through the finite group G/U. (e) Each construction is given in suitable bases by matrices whose entries are polynomials in the entries of $\rho(g)$, $\rho'(g)$ and $\det\rho(g)^{-1}$; these are continuous. A subrepresentation (or quotient) is given, in a basis adapted to it, by a block of the matrix. The semisimplification is the direct sum of the composition factors (Jordan-Hölder, Chapter 3 and Chapter 4), which are subquotients. □

By (a), the characters χ_d and $\bar\chi_\ell$ are continuous, their kernels $G_{\mathbb{Q}(\sqrt{d})}$ and $G_{\mathbb{Q}(\zeta_\ell)}$ being open; χ_ℓ is continuous by Proposition 5.59(a). Continuity is a genuine condition: if U is one of the

subgroups of index 2 of $\mathrm{Gal}(L/\mathbb{Q})$ that are not open (Example 5.55(2), L the compositum of all quadratic fields), the composite $G_{\mathbb{Q}} \to \mathrm{Gal}(L/\mathbb{Q}) \to \mathrm{Gal}(L/\mathbb{Q})/U \simeq \{\pm 1\}$ is a homomorphism whose kernel is not open, hence not closed (a closed subgroup of finite index is open), so it is not of the form G_K and the character cuts out no field.

Proposition 5.63 (Quadratic characters of $G_{\mathbb{Q}}$)**.** *(a) $d \mapsto \chi_d$ is an isomorphism $\mathbb{Q}^\times/\mathbb{Q}^{\times 2} \simeq \mathrm{Hom}_{\mathrm{cont}}(G_{\mathbb{Q}}, \{\pm 1\})$, with $\ker \chi_d = G_{\mathbb{Q}(\sqrt{d})}$; the nontrivial continuous quadratic characters of $G_{\mathbb{Q}}$ correspond to the quadratic fields.*

(b) $\chi_{dd'} = \chi_d \chi_{d'}$. For example $\chi_{-15} = \chi_{-3}\chi_5$, and $\chi_{-4}\chi_{-3} = \chi_{12}$ is the character of $\mathbb{Q}(\sqrt{3})$ (written by its discriminant 12; the symbol χ_3 is never used, Convention 5.3); and for a finite set S of odd primes $\chi_S = \prod_{q\in S} \chi_{q^*}$ is the character of $\mathbb{Q}(\sqrt{\prod_{q\in S} q^*})$.

(c) For a prime $p \nmid D$, D the discriminant of $\mathbb{Q}(\sqrt{d})$: $\chi_d(\mathrm{Frob}_p) = \left(\frac{D}{p}\right)$ (Kronecker symbol), which is 1 iff p splits in $\mathbb{Q}(\sqrt{d})$. In particular $\chi_{-3}(\mathrm{Frob}_p) = 1$ iff $p \equiv 1 \pmod 3$, $\chi_{-4}(\mathrm{Frob}_p) = 1$ iff $p \equiv 1 \pmod 4$, and for odd $\ell \neq p$, $\chi_{\ell^*}(\mathrm{Frob}_p) = \left(\frac{p}{\ell}\right)$.

(d) As a Dirichlet character (Chapter 2), χ_d has conductor $|D|$: χ_{q^*} has conductor q, χ_{-3} conductor 3, χ_{-4} conductor 4.

Proof of (a), (b) and of the last formula of (c); (c), (d) otherwise stated. (a) is Corollary 5.56 with $F = \mathbb{Q}$, $n = 2$, and Proposition 5.27(c). (b) $\sqrt{dd'} = \pm\sqrt{d}\sqrt{d'}$, and $\chi_{dd'}$ does not depend on the choice of square root. The last formula of (c) is a direct consequence of $\chi_{\ell^*} = \left(\frac{\bar\chi_\ell}{\ell}\right)$ (Proposition 5.29) and $\bar\chi_\ell(\mathrm{Frob}_p) = p \bmod \ell$ (Theorem 5.72(c)). The general formula in (c) and (d) are proved in Chapter 6 and Chapter 2; we do not prove them here. Comparing $\chi_{\ell^*}(\mathrm{Frob}_p) = \left(\frac{p}{\ell}\right)$ with $\chi_{\ell^*}(\mathrm{Frob}_p) = \left(\frac{\ell^*}{p}\right)$ from (c) is quadratic reciprocity (Chapter 2). □

The formulas of (c) were also checked numerically: for $5 \le p < 2000$, x^2+3 has a root modulo p iff $p \equiv 1 \pmod 3$, x^2+1 iff $p \equiv 1 \pmod 4$, and for $\ell \in \{3,5,7,11,13\}$, ℓ^* is a square modulo p iff p is a square modulo ℓ.

Proposition 5.64 (Twists)**.** *Let $\rho\colon G \to \mathrm{GL}_n(k)$ and $\chi\colon G \to k^\times$ be continuous (k a field or $\mathcal{O}$ as above).*

(a) $\rho \otimes \chi\colon g \mapsto \chi(g)\rho(g)$ is continuous, $\mathrm{tr}(\rho\otimes\chi)(g) = \chi(g)\,\mathrm{tr}\,\rho(g)$ and $\det(\rho\otimes\chi) = \chi^n \det\rho$. For $G = G_F$ the field cut out by $\rho\otimes\chi$ lies in $F_\rho F_\chi$.

(b) If $n = 2$ and $\rho \simeq \rho\otimes\chi$, then $\chi^2 = 1$. If moreover k is a field, $\chi \neq 1$ and ρ is absolutely irreducible, every isomorphism $\rho \to \rho\otimes\chi$ has trace 0, and these isomorphisms form a line together with 0.

(c) Let ℓ be odd, $\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{Z}_\ell)$ continuous and $k \ge 1$. If $\rho \bmod \ell^k \simeq (\rho\otimes\chi_\ell) \bmod \ell^k$ (conjugate by an element of $\mathrm{GL}_2(\mathbb{Z}/\ell^k)$), then $\chi_\ell(g)^2 \equiv 1 \pmod{\ell^k}$ for all $g \in G_{\mathbb{Q}}$, and this forces $\ell = 3$ and $k = 1$. For $\ell = 3$, $k = 1$ the condition reads $\bar\rho \simeq \bar\rho \otimes \bar\chi_3 = \bar\rho \otimes \chi_{-3}$.

Proof. (a) The formulas are immediate; continuity is Proposition 5.62(e). The kernel of $\rho\otimes\chi$ contains $\ker\rho \cap \ker\chi = G_{F_\rho F_\chi}$ (Theorem 5.52(c) and Theorem 5.23(e) in the limit). (b) Taking determinants of $P\rho(g)P^{-1} = \chi(g)\rho(g)$ gives $\det\rho(g) = \chi(g)^2 \det\rho(g)$, and $\det\rho(g)$ is a unit. The rest is the trace-zero lemma of Chapter 4: a G-map $\phi\colon \rho \to \rho\otimes\chi$ satisfies $(1-\chi(g))\,\mathrm{tr}\,\phi = 0$, and $\mathrm{Hom}_G(\rho, \rho\otimes\chi)$ has dimension at most one with nonzero elements isomorphisms when ρ

is absolutely irreducible. (c) Let $P \in \mathrm{GL}_2(\mathbb{Z}/\ell^k)$ with $P\rho(g)P^{-1} \equiv \chi_\ell(g)\rho(g) \pmod{\ell^k}$ for all g. Taking determinants in $\mathbb{Z}/\ell^k$ gives $\det\rho(g) \equiv \chi_\ell(g)^2 \det\rho(g)$, and $\det\rho(g) \in \mathbb{Z}_\ell^\times$ is a unit modulo ℓ^k; so $\chi_\ell(g)^2 \equiv 1 \pmod{\ell^k}$ for all g. (This is the argument of (b), which works over any commutative ring.) By Proposition 5.59(b) there is g with $\chi_\ell(g) = 2$ ($2 \in \mathbb{Z}_\ell^\times$ as ℓ is odd), so $\ell^k \mid 4-1=3$: $\ell = 3$ and $k = 1$. For $\ell = 3$, $k = 1$ there is no contradiction: $\bar\chi_3$ takes the values ±1, whose squares are 1. Finally $\bar\chi_3 = \chi_{-3}$ by Proposition 5.29(c). □

In the paper 5.65. Lemma lem:h0 identifies $h_\ell(E)$, the length of $H^0(\mathbb{Q}, \mathrm{ad}^0 T(1) \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell)$, with the largest k such that $\rho \bmod \ell^k \simeq (\rho \otimes \chi_\ell) \bmod \ell^k$ (the module-theoretic part, Nakayama and cyclicity, is Chapter 4). Proposition 5.64(c) is then the step "Taking determinants, $\chi_\ell(g)^2 \equiv 1 \pmod{\ell^k}$ for all $g \in G_\mathbb{Q}$. Since $\chi_\ell(G_\mathbb{Q}) = \mathbb{Z}_\ell^\times$ contains 2, ... this forces $k = 0$ for $\ell \geq 5$ and $k \leq 1$ for $\ell = 3$": $h_\ell(E) = 0$ for $\ell \geq 5$ and $h_3(E) \leq 1$, for every E with $\bar\rho$ irreducible, with or without complex multiplication. It holds for every continuous $\rho\colon G_\mathbb{Q} \to \mathrm{GL}_2(\mathbb{Z}_\ell)$, irreducible or not. The argument needs the cyclotomic character χ_ℓ, not the quadratic character χ_{ℓ^*}, which differs from $\bar\chi_\ell$ for $\ell \geq 5$ (Proposition 5.29).

Proposition 5.66 (Restriction to open subgroups)**.** *Let K/F be a finite separable extension inside F^{sep} and $\rho\colon G_F \to \mathrm{GL}_n(k)$ continuous.*

(a) $\mathrm{Res}\,\rho = \rho|_{G_K}$ *is continuous, and* $[\rho(G_F) : \rho(G_K)] \leq [K : F]$. *If K/F is Galois, $\rho(G_K)$ is normal in $\rho(G_F)$ and the index divides $[K : F]$.*

(b) (Image of a kernel.) If $\delta\colon \mathrm{GL}_n(k) \to A$ is a homomorphism to an abelian group and $G_K = \ker(\delta \circ \rho)$ (that is, K is cut out by $\delta \circ \rho$), then $\rho(G_K) = \rho(G_F) \cap \ker\delta$.

(c) Let $E/\mathbb{Q}$ be an elliptic curve, ℓ odd and $\bar\rho = \bar\rho_{E,\ell}$, with $\det\bar\rho = \bar\chi_\ell$ (Chapter 9). Then $\bar\rho(G_{\mathbb{Q}(\zeta_\ell)}) = \bar\rho(G_\mathbb{Q}) \cap \mathrm{SL}_2(\mathbb{F}_\ell)$ and $\bar\rho(G_{\mathbb{Q}(\sqrt{\ell^*})}) = \{g \in \bar\rho(G_\mathbb{Q}) : \det g \in (\mathbb{F}_\ell^\times)^2\}$. For $\ell = 3$ both are the determinant-one subgroup of the image.

(d) The field cut out by $\mathrm{Res}\,\rho$ *is KF_ρ, and* $\mathrm{Gal}(KF_\rho/K) \simeq \mathrm{Gal}(F_\rho/F_\rho \cap K)$.

(e) ρ is absolutely irreducible on G_K iff the subgroup $\rho(G_K)$ fixes no proper nonzero subspace of $\bar k^n$; this depends only on $\rho(G_K)$.

Proof. (a) Restriction of a continuous map. The cosets of G_K (there are $[K : F]$ of them, Proposition 5.54(a)) map onto the cosets of $\rho(G_K)$. If K/F is Galois, G_K is normal, so $\rho(G_K)$ is normal in $\rho(G_F)$, and $\rho(G_F)/\rho(G_K)$ is a quotient of $G_F/G_K \simeq \mathrm{Gal}(K/F)$. (b) If $g \in G_K$ then $\delta(\rho(g)) = 1$. Conversely if $\rho(g) \in \ker\delta$ then $g \in \ker(\delta\circ\rho) = G_K$; so every element of $\rho(G_F) \cap \ker\delta$ is in $\rho(G_K)$. (c) $\mathbb{Q}(\zeta_\ell)$ is cut out by $\bar\chi_\ell = \det\circ\bar\rho$ (Proposition 5.59(c)): take $\delta = \det$. $\mathbb{Q}(\sqrt{\ell^*})$ is cut out by $\chi_{\ell^*} = (\frac{\bar\chi_\ell}{\ell}) = (\frac{\det\bar\rho}{\ell})$ (Proposition 5.29): take $\delta = (\frac{\det}{\ell})$. For $\ell = 3$, $(\mathbb{F}_3^\times)^2 = \{1\}$. (d) The kernel of $\mathrm{Res}\,\rho$ is $G_K \cap \ker\rho = G_K \cap G_{F_\rho} = G_{KF_\rho}$ (Theorem 5.52). The isomorphism is Corollary 5.57. (e) Definition (Convention 5.4); the stable subspaces of $\bar k^n$ under G_K are those under $\rho(G_K)$. □

Proposition 5.67 (Index two)**.** *Let G be a profinite group, $H \subseteq G$ an open subgroup of index 2, $\chi\colon G \to G/H \simeq \{\pm1\}$, $s \in G \setminus H$, k a field with* $\mathrm{char}\,k \neq 2$ *(discrete, or a finite extension of $\mathbb{Q}_\ell$), and $\rho\colon G \to \mathrm{GL}_2(k)$ continuous and absolutely irreducible. The following are equivalent:*

(i) $\rho|_H$ is not absolutely irreducible;

(ii) $\rho \simeq \rho \otimes \chi$ (over k; equivalently over $\bar k$);

(iii) $\rho \otimes \bar{k} \simeq \operatorname{Ind}_H^G \psi$ *for a continuous character* $\psi\colon H \to \bar{k}^\times$.

When they hold, $\rho|_H \otimes \bar{k} \simeq \psi \oplus \psi^s$ *with* $\psi^s(h) = \psi(s^{-1}hs)$ *and* $\psi^s \neq \psi$*, and every isomorphism* $\rho \to \rho \otimes \chi$ *has trace* 0*. For* $G = G_{\mathbb{Q}}$ *and* $H = G_K$*,* K *quadratic,* $\chi = \chi_d$ *is the character of* $K = \mathbb{Q}(\sqrt{d})$.

Proof. This is the Clifford theory for a subgroup of index two of Chapter 4, applied to the abstract group G; the equivalence (ii) over k and over $\bar{k}$ holds because spaces of G-maps commute with extension of scalars (Chapter 4). Only continuity needs comment. In (iii), ψ is the character by which H acts on a line $\bar{k}w \subset \bar{k}^2$ stable under $\rho(H)$. The coordinates of w generate a finite extension k' of k, so $\psi(h) = \rho(h)w/w \in k'$, and in a basis w, w' of k'^2 the value $\psi(h)$ is the upper left entry of the matrix of $\rho(h)$, a continuous function of h (k' discrete if k is, and with its ℓ-adic topology if k is a finite extension of $\mathbb{Q}_\ell$). Conversely, $\operatorname{Ind}_H^G \psi$ for continuous ψ is continuous: in the basis $\{v, sv\}$ its matrix entries are values of ψ at h, $s^{-1}hs$ or products with $\psi(s^2)$, all continuous functions of $h \in H$ and $g \in G$ (H being open and closed). □

The mechanism behind (i)⇒(iii)⇒(ii) is short enough to recall. Let $\bar{k}w$ be a line stable under $\rho(H)$, on which H acts by ψ. For $h \in H$, $s^{-1}hs \in H$ (H is normal, having index 2), so $\rho(h)\rho(s)w = \rho(s)\rho(s^{-1}hs)w = \psi^s(h)\rho(s)w$: the line $\bar{k}\rho(s)w$ is stable under H, with character ψ^s. It differs from $\bar{k}w$, since otherwise $\bar{k}w$ would be stable under $H \cup sH = G$, against absolute irreducibility. In the basis $w, \rho(s)w$, every $\rho(h)$ is $\operatorname{diag}(\psi(h), \psi^s(h))$ and $\rho(s) = \left(\begin{smallmatrix} 0 & \psi(s^2) \\ 1 & 0 \end{smallmatrix}\right)$ swaps the two lines: this is the matrix form of $\operatorname{Ind}_H^G \psi$. The matrix $P = \operatorname{diag}(1, -1)$ commutes with the diagonal $\rho(h)$, and $P\rho(s)P^{-1} = -\rho(s)$; as $\chi(h) = 1$ and $\chi(s) = -1$, $P\rho(g)P^{-1} = \chi(g)\rho(g)$ for all $g \in H \cup sH$, so P is an isomorphism $\rho \otimes \bar{k} \to (\rho \otimes \chi) \otimes \bar{k}$, of trace 0.

In the paper 5.68. For $\bar{\rho} = \bar{\rho}_{E,\ell}$, irreducible, hence absolutely irreducible by Proposition 5.60(d), and $K = \mathbb{Q}(\sqrt{\ell^*})$: condition (i) is the failure of the hypothesis of Theorem thm:main (DFG04's $\ell \in S_f$). For $\ell = 3$, $\chi_{-3} = \bar{\chi}_3$, and (ii) says that the space of $G_{\mathbb{Q}}$-maps $\bar{\rho} \to \bar{\rho} \otimes \bar{\chi}_3$, which are automatically of trace zero, is nonzero: $H^0(\mathbb{Q}, \operatorname{ad}^0 \bar{\rho}(1)) \neq 0$, the condition $h_3(E) = 1$ of Lemma lem:h0; and by (iii) it happens exactly when $\bar{\rho} \otimes \mathbb{F}_9$ is induced from $G_{\mathbb{Q}(\sqrt{-3})}$, the case $N_s(\mathbb{F}_3)$ of Proposition prop:ns (Proposition 5.47(f) and Chapter 4: the determinant-one subgroup C_4 of $N_s(\mathbb{F}_3)$ is abelian, so $\bar{\rho}|_{G_{\mathbb{Q}(\sqrt{-3})}} \otimes \mathbb{F}_9 = \psi \oplus \psi^{-1}$ with ψ of order 4). For $\ell \geq 5$, (ii) for χ_{ℓ^*} can hold (the dihedral case excluded by S_f; by Proposition prop:Sf only when $\ell \mid N$), but it is not the condition $\bar{\rho} \simeq \bar{\rho} \otimes \bar{\chi}_\ell$ of Lemma lem:h0, which never holds for $\ell \geq 5$ (Proposition 5.64(b): it would force $\bar{\chi}_\ell^2 = 1$).

Proposition 5.69 (Reduction and semisimplification)**.** *Let* E_λ *be a finite extension of* $\mathbb{Q}_\ell$ *with ring of integers* $\mathcal{O}$*, uniformiser* ϖ *and residue field* k*,* G *a profinite group, and* $\rho\colon G \to \mathrm{GL}_n(E_\lambda)$ *continuous. For two* G*-stable lattices* Λ, Λ'*, the reductions* $\bar{\rho}_\Lambda$*,* $\bar{\rho}_{\Lambda'}$ *have the same characteristic polynomials, namely the reductions of the characteristic polynomials of* ρ*, which lie in* $\mathcal{O}[X]$*; hence* $\bar{\rho}_\Lambda^{ss} \simeq \bar{\rho}_{\Lambda'}^{ss}$*, and* $\bar{\rho}^{ss}$ *is well defined. If* $\bar{\rho}_\Lambda$ *is irreducible, then* $\Lambda' = \varpi^m \Lambda$ *for some* $m \in \mathbb{Z}$.

Proof. In a basis of Λ the matrix of $\rho(g)$ lies in $\mathrm{GL}_n(\mathcal{O})$, so $\det(X - \rho(g)) \in \mathcal{O}[X]$, and it does not depend on the basis of E_λ^n; its reduction is the characteristic polynomial of $\bar{\rho}_\Lambda(g)$, and likewise for Λ'. Brauer-Nesbitt (Chapter 4, valid for any group and any field) gives $\bar{\rho}_\Lambda^{ss} \simeq \bar{\rho}_{\Lambda'}^{ss}$. The last statement is the homothety lemma of Chapter 4. □

Proposition 5.70 (The ℓ-adic Kummer cocycle)**.** *Let* $\ell \neq \operatorname{char} F$ *be a prime and* $a \in F^\times$*. Choose a compatible system* $(\alpha_k)_{k \geq 0}$ *in* F^{sep} *with* $\alpha_0 = a$ *and* $\alpha_{k+1}^\ell = \alpha_k$*, and define, in the additive*

notation of Convention 5.3(c),

$$\kappa_a\colon G_F \to \mathbb{Z}_\ell(1), \qquad \kappa_a(\sigma) = \big(\sigma(\alpha_k)/\alpha_k\big)_{k\ge 0}.$$

(a) *κ_a is continuous and $\kappa_a(\sigma\tau) = \kappa_a(\sigma) + \chi_\ell(\sigma)\kappa_a(\tau)$: a continuous 1-cocycle (Chapter 16). Equivalently, writing $\kappa_a(\sigma) = b(\sigma)e$ for a generator e of $\mathbb{Z}_\ell(1)$,*

$$\sigma \longmapsto \begin{pmatrix} \chi_\ell(\sigma) & b(\sigma) \\ 0 & 1 \end{pmatrix}$$

is a continuous homomorphism $G_F \to \mathrm{GL}_2(\mathbb{Z}_\ell)$: the action on $\mathbb{Z}_\ell e_1 \oplus \mathbb{Z}_\ell e_2$ with $e_1 = e$, $\sigma e_1 = \chi_\ell(\sigma)e_1$, $\sigma e_2 = e_2 + b(\sigma)e_1$.

(b) *Another compatible system changes κ_a by the coboundary $\sigma \mapsto (\chi_\ell(\sigma) - 1)z$ for some $z \in \mathbb{Z}_\ell(1)$. For the product systems, $\kappa_{aa'} = \kappa_a + \kappa_{a'}$ for $a, a' \in F^\times$. The k-th component of κ_a, restricted to $G_{F(\mu_{\ell^k})}$, is the Kummer character χ_a with $n = \ell^k$.*

(c) *On $\ker\chi_\ell = G_{F(\mu_{\ell^\infty})}$, κ_a is a homomorphism, and for $\sigma \in G_F$, $\tau \in \ker\chi_\ell$: $\kappa_a(\sigma\tau\sigma^{-1}) = \chi_\ell(\sigma)\kappa_a(\tau)$.*

(d) *If $K \supseteq F$ contains μ_{ℓ^k}, then $\kappa_a \bmod \ell^k$ vanishes on G_K iff $a \in (K^\times)^{\ell^k}$.*

Proof. (a) $(\sigma(\alpha_k)/\alpha_k)^{\ell^k} = \sigma(a)/a = 1$, and $(\sigma(\alpha_{k+1})/\alpha_{k+1})^{\ell} = \sigma(\alpha_k)/\alpha_k$, so $\kappa_a(\sigma) \in \mathbb{Z}_\ell(1)$. Multiplicatively,

$$\frac{\sigma\tau(\alpha_k)}{\alpha_k} = \sigma\Big(\frac{\tau(\alpha_k)}{\alpha_k}\Big)\cdot\frac{\sigma(\alpha_k)}{\alpha_k},$$

and σ acts on μ_{ℓ^k} by raising to the power $\chi_\ell(\sigma)$; additively this is the cocycle relation. The k-th component is constant on the cosets of the open subgroup $G_{F(\mu_{\ell^k},\alpha_k)}$ (for τ in it, $\kappa_a(\sigma\tau)_k = \kappa_a(\sigma)_k + \chi_\ell(\sigma)\kappa_a(\tau)_k = \kappa_a(\sigma)_k$), so κ_a is continuous. The matrix identity $\left(\begin{smallmatrix}\chi(\sigma) & b(\sigma)\\ 0 & 1\end{smallmatrix}\right)\left(\begin{smallmatrix}\chi(\tau) & b(\tau)\\ 0 & 1\end{smallmatrix}\right) = \left(\begin{smallmatrix}\chi(\sigma\tau) & b(\sigma)+\chi(\sigma)b(\tau)\\ 0 & 1\end{smallmatrix}\right)$ is the cocycle relation. (b) Another system is $(\epsilon_k\alpha_k)$ with $\epsilon = (\epsilon_k) \in \mathbb{Z}_\ell(1)$, and $\sigma(\epsilon_k\alpha_k)/\epsilon_k\alpha_k = (\sigma(\epsilon_k)/\epsilon_k)\cdot\sigma(\alpha_k)/\alpha_k$; additively the change is $\sigma(\epsilon) - \epsilon = (\chi_\ell(\sigma) - 1)\epsilon$. Additivity in a is clear. On $G_{F(\mu_{\ell^k})}$ the k-th component is $\sigma(\alpha_k)/\alpha_k = \chi_a(\sigma)$ by definition (Proposition 5.35, over $F(\mu_{\ell^k})$, with $n = \ell^k$, $\alpha = \alpha_k$). (c) For $\tau, \tau' \in \ker\chi_\ell$ the cocycle relation reads $\kappa_a(\tau\tau') = \kappa_a(\tau) + \kappa_a(\tau')$. From $0 = \kappa_a(1) = \kappa_a(\sigma\sigma^{-1}) = \kappa_a(\sigma) + \chi_\ell(\sigma)\kappa_a(\sigma^{-1})$ and $\chi_\ell(\tau) = 1$:

$$\kappa_a(\sigma\tau\sigma^{-1}) = \kappa_a(\sigma) + \chi_\ell(\sigma)\big(\kappa_a(\tau) + \kappa_a(\sigma^{-1})\big) = \chi_\ell(\sigma)\kappa_a(\tau).$$

(d) $G_K \subseteq G_{F(\mu_{\ell^k})}$, so by (b) $\kappa_a \bmod \ell^k$ on G_K is the Kummer character of a over K with $n = \ell^k$; it is trivial iff $a \in (K^\times)^{\ell^k}$ by Proposition 5.35(b). □

The Kummer representation also illustrates Proposition 5.69. Let ℓ be odd, $F = \mathbb{Q}$, $a = 2$, and ρ the representation of (a) on $\Lambda = \mathbb{Z}_\ell e_1 \oplus \mathbb{Z}_\ell e_2$. The lattice $\Lambda' = \mathbb{Z}_\ell e_1 \oplus \mathbb{Z}_\ell\, \ell e_2$ is also stable, since $\sigma(\ell e_2) = \ell e_2 + \ell b(\sigma)e_1$; in the basis $e_1, \ell e_2$ the matrix is $\left(\begin{smallmatrix}\chi_\ell & \ell b\\ 0 & 1\end{smallmatrix}\right)$, with reduction $\mathrm{diag}(\bar\chi_\ell, 1)$, which is semisimple. On Λ the reduction is $\left(\begin{smallmatrix}\bar\chi_\ell & \bar b\\ 0 & 1\end{smallmatrix}\right)$, and $\bar b = b \bmod \ell$ is not identically zero on $G_{\mathbb{Q}(\zeta_\ell)}$ by (d), because 2 is not an ℓ-th power in $\mathbb{Q}(\zeta_\ell)$ ($x^\ell - 2$ is Eisenstein, so an ℓ-th root of 2 has degree ℓ over $\mathbb{Q}$, which does not divide $\ell - 1 = [\mathbb{Q}(\zeta_\ell) : \mathbb{Q}]$). An element of $G_{\mathbb{Q}(\zeta_\ell)}$ with $\bar b \neq 0$ acts by a nontrivial unipotent matrix, whose only stable line is $\mathbb{F}_\ell e_1$; so the reduction on Λ is not

semisimple. Both reductions have semisimplification $\bar{\chi}_\ell \oplus 1$, as the proposition says, but they are not isomorphic, and Λ' is not homothetic to Λ; this does not contradict the last statement of the proposition because neither reduction is irreducible.

In the paper 5.71. In the proof of Lemma lem:tamfactor, $F = \mathbb{Q}_q$ with $q \neq \ell$, $a = q_E$ is the Tate parameter, and over the unramified quadratic extension the action on $T_\ell E$ in the basis $e_1 = (\zeta_{\ell^k})_k$, $e_2 = (q_E^{1/\ell^k})_k$ is the matrix of (a) (Chapter 10); for the nonsplit curve it is twisted by the unramified character ε, giving $\left(\begin{smallmatrix} \chi_\ell\varepsilon & \varepsilon\kappa \\ 0 & \varepsilon \end{smallmatrix}\right)$. Part (c) with $\sigma = \mathrm{Frob}$ and $\tau = t$ a generator of the pro-ℓ tame inertia quotient (on which χ_ℓ is trivial, Chapter 7) gives $\kappa(\mathrm{Frob}\; t\; \mathrm{Frob}^{-1}) = q\kappa(t)$, the abstract form of the tame relation $\mathrm{Frob}\; t\; \mathrm{Frob}^{-1} = t^q$, equivalently $\mathrm{Frob}^{-1}\, t\, \mathrm{Frob} = t^{q^{-1}}$, which the paper uses. By (b), $\kappa_{q_E} = n\kappa_q + \kappa_u$ for $q_E = q^n u$; the restriction of κ_u to inertia vanishes (the unit u has ℓ-power roots in $\mathbb{Q}_q^{\mathrm{ur}}$, by Hensel, Chapter 7), and the restriction of κ_q to inertia is the tame character, whence "the restriction of κ to I is n times the tame character". In Lemma lem:tamagawa-exp, (d) with $K = \mathbb{Q}_q^{\mathrm{ur}}$ and $G_K = I_q$ says that inertia acts trivially on $E[\ell^t]$ iff $q_E \in (\mathbb{Q}_q^{\mathrm{ur},\times})^{\ell^t}$; Chapter 7 turns this into $\ell^t \mid n_q$. The value $c' = \varepsilon\kappa(\mathrm{Frob})$ depends on the choices (by (b) and on the lift of Frob), and only its class modulo $(n, q-1)\mathbb{Z}_\ell$ is meaningful, which does not affect the minimum in the lemma (Chapter 17).

5.9 Frobenius elements and the Chebotarev density theorem

The step "$\bar{\rho}_h \simeq \bar{\rho}$ by Chebotarev and Brauer-Nesbitt" in Lemma lem:old compares two residual representations through the characteristic polynomials of Frobenius elements, which are known only at the primes not dividing ℓN. This section states what Frobenius elements are (they are constructed in Chapter 6; no theorem of Sections 1 to 7 depends on them, and in Sections 6 and 8 they enter only through the stated Theorem 5.72, in Example 5.49 and Proposition 5.63(c)), states the Chebotarev density theorem, and proves the consequences used in the paper: Frobenius elements are dense, so a semisimple representation is determined by their characteristic polynomials, and congruent traces give isomorphic residual representations. A worked example checks the factorisation patterns of ψ_3 against Frobenius, as the test of Section sec:data does.

Theorem 5.72 (Frobenius elements)**.** *Let $K/\mathbb{Q}$ be a finite Galois extension with ring of integers $\mathcal{O}_K$, and p a prime unramified in K (Chapter 6).*

(a) For each prime $\mathfrak{P}$ of $\mathcal{O}_K$ above p there is a unique $\mathrm{Frob}_\mathfrak{P} \in \mathrm{Gal}(K/\mathbb{Q})$ with $\mathrm{Frob}_\mathfrak{P}(x) \equiv x^p \pmod{\mathfrak{P}}$ for all $x \in \mathcal{O}_K$. The $\mathrm{Frob}_\mathfrak{P}$, $\mathfrak{P} \mid p$, form one conjugacy class Frob_p ($\mathrm{Frob}_{\sigma\mathfrak{P}} = \sigma\,\mathrm{Frob}_\mathfrak{P}\,\sigma^{-1}$). The order of $\mathrm{Frob}_\mathfrak{P}$ is the residue degree $[\mathcal{O}_K/\mathfrak{P} : \mathbb{F}_p]$, and p splits completely in K iff $\mathrm{Frob}_p = 1$.

(b) For $K' \subseteq K$ Galois over $\mathbb{Q}$, $\mathrm{Frob}_\mathfrak{P}$ restricts to $\mathrm{Frob}_{\mathfrak{P}\cap K'}$; so $\mathrm{Frob}_p(K/\mathbb{Q})$ maps to $\mathrm{Frob}_p(K'/\mathbb{Q})$.

(c) In $\mathbb{Q}(\zeta_n)$ with $p \nmid n$, $\mathrm{Frob}_p = \sigma_p$; hence $\bar{\chi}_\ell(\mathrm{Frob}_p) = p \bmod \ell$ and $\chi_\ell(\mathrm{Frob}_p) = p$ for $p \neq \ell$. In $\mathbb{Q}(\sqrt{d})$ with $p \nmid D$, $\chi_d(\mathrm{Frob}_p) = \left(\frac{D}{p}\right)$.

(d) For $L/\mathbb{Q}$ Galois of any degree, unramified at p (that is, every finite subextension is), the Frobenius elements at the primes of L above p (compatible systems of primes of the finite subextensions) are the elements $\mathrm{Frob}_\mathfrak{P} \in \mathrm{Gal}(L/\mathbb{Q})$ restricting to $\mathrm{Frob}_{\mathfrak{P}\cap K}$ for each finite Galois $K \subseteq L$; they form one conjugacy class. In $G_\mathbb{Q}$ a Frobenius element at p is well defined up to conjugation and up to the inertia group at a prime above p; so for a continuous

representation ρ of $G_{\mathbb{Q}}$ unramified at p (trivial on the inertia groups at p), the conjugacy class of $\rho(\mathrm{Frob}_p)$, and in particular its characteristic polynomial, is well defined.

(e) (Dedekind.) Let $f \in \mathbb{Z}[x]$ be separable with leading coefficient a, and $p \nmid a\,\mathrm{disc}(f)$. If $f \bmod p$ has irreducible factors of degrees $d_1, \dots, d_r$, then p is unramified in the splitting field of f and Frob_p acts on the roots of f with cycle type $(d_1, \dots, d_r)$.

We do not prove this here; see Chapter 6, and [142, Chapter I, Section 9] (decomposition groups and Frobenius) and [142, Chapter I, Section 8] (the factorisation of p through $f \bmod p$); the section numbers in this book are pointers we have not re-verified. The finite-field part is proved here: the residue extension $(\mathcal{O}_K/\mathfrak{P})/\mathbb{F}_p$ is cyclic generated by Frob_p (Theorem 5.25), and $\mathrm{Frob}_{\mathfrak{P}}$ is the lift of that generator, which exists and is unique when p is unramified. Note the convention (Convention 5.2): Frob_p is arithmetic.

For example, in $\mathbb{Q}(i) = \mathbb{Q}(\zeta_4)$ and for odd p, $\mathrm{Frob}_p = \sigma_p$ sends i to i^p, which is i for $p \equiv 1 \pmod 4$ and $-i$ for $p \equiv 3 \pmod 4$. By (a), p splits completely in $\mathbb{Q}(i)$ exactly when $p \equiv 1 \pmod 4$, and $\chi_{-4}(\mathrm{Frob}_p) = (-1)^{(p-1)/2}$, in accordance with (c).

Example 5.73 (Frobenius on the four lines)**.** Let $E/\mathbb{Q}$ have good reduction at a prime $p \neq 3$ with $p \nmid \mathrm{disc}(\psi_3)$. Then $\bar\rho_{E,3}$ is unramified at p and $\bar\rho_{E,3}(\mathrm{Frob}_p)$ has characteristic polynomial $X^2 - a_p X + p \bmod 3$ (Chapter 9, Chapter 11). By Theorem 5.72(e) and Proposition 5.47, the degrees of the irreducible factors of $\psi_3 \bmod p$ are the orbit sizes of $g = \bar\rho_{E,3}(\mathrm{Frob}_p)$ on the four lines. These depend only on the characteristic polynomial, except in the last case:

- $X^2 \pm X - 1$: the eigenvalues $\lambda, \lambda^3 \in \mathbb{F}_9 \setminus \mathbb{F}_3$ satisfy $\lambda^4 = \det g = -1$, so λ has order 8 and g has order 4 in $\mathrm{PGL}_2(\mathbb{F}_3)$ with no fixed line: a 4-cycle, pattern (4);
- $X^2 + 1$: $g^2 = -1$, so g is an involution on the lines, without fixed line (no eigenvalue in $\mathbb{F}_3$): pattern $(2,2)$;
- $X^2 - 1$: $g \sim \mathrm{diag}(1,-1)$ fixes its two eigenlines and swaps the other two: pattern $(1,1,2)$;
- $(X \mp 1)^2$: $g = \pm(1+N)$ with N nilpotent; if $N \neq 0$, g fixes one line and has order 3 in $\mathrm{PGL}_2(\mathbb{F}_3)$: pattern $(1,3)$; if $g = \pm 1$: $(1,1,1,1)$.

For 11a1 ($a_2 = -2$, $a_5 = 1$, $a_7 = -2$, $a_{13} = 4$, $a_{17} = -2$, $a_{19} = 0$, $a_{23} = -1$, $a_{29} = 0$, $a_{31} = 7$, $a_{37} = 3$; $\mathrm{disc}\,\psi_3 = -3^3 \cdot 11^{10}$) we checked with PARI that $\psi_3 \bmod p$ has the pattern (4) for $p = 2, 5, 17, 23$, $(1,3)$ for $p = 7, 13, 31$, $(2,2)$ for $p = 19, 37$ and $(1,1,2)$ for $p = 29$, as predicted. The pattern $(1,1,2)$ at $p = 29$ means that Frob_{29} fixes two lines, although the image is $\mathrm{GL}_2(\mathbb{F}_3)$: Frobenius elements see conjugacy classes, not the image.

Definition 5.74 (Density)**.** Let X be a set of primes. Its *Dirichlet density* is

$$\lim_{s \to 1^+} \frac{\sum_{p \in X} p^{-s}}{\log \frac{1}{s-1}},$$

and its *natural density* is $\lim_{x\to\infty} \#\{p \le x : p \in X\}/\#\{p \le x\}$, when these limits exist. A set with a natural density has the same Dirichlet density (we do not use the converse, which is false). Finite sets have density 0, a subset of a set of density 0 has density 0 (the sums are nonnegative), and densities are additive on disjoint unions of sets that have densities. X has *density one* if its complement has density 0. "*Almost all p*" means all but finitely many. Unless stated otherwise, density means Dirichlet density.

The sets of density one used in the paper are the simplest ones: for a fixed integer N, the primes $p \nmid N$ form a set of density one, its complement being finite. So a hypothesis "for all p in a set of density one" in the corollaries below is satisfied as soon as the statement holds for all $p \nmid N$; the extra generality costs nothing and allows one to discard any set of density 0.

For the comparison of the two densities see [172, Chapter VI, Section 4]; the normalisation uses $\sum_p p^{-s} \sim \log \frac{1}{s-1}$ as $s \to 1^+$, which is proved there.

Theorem 5.75 (Chebotarev's density theorem)**.** *Let $K/\mathbb{Q}$ be a finite Galois extension with group G and $C \subseteq G$ a conjugacy class. The set of primes p, unramified in K, with $\mathrm{Frob}_p = C$ has Dirichlet density $\#C/\#G$; it also has natural density $\#C/\#G$. The same holds for a finite Galois extension of number fields, with the primes of the base field. In particular every conjugacy class is Frob_p for infinitely many p.*

We do not prove this; see [142, Chapter VII, Section 13] for the Dirichlet density and [178, Chapter I, Section 2.2] for the statement with natural density; the book uses only the positivity of the Dirichlet density. Special cases: for $K = \mathbb{Q}(\zeta_n)$ (Theorem 5.72(c)) it is Dirichlet's theorem, each class $a \in (\mathbb{Z}/n)^\times$ containing primes of density $1/\varphi(n)$; for $K = \mathbb{Q}(\sqrt{d})$, half of the primes split. For the splitting field of $x^3 - 2$ (Example 5.31, group S_3) and $p \nmid 6$, Theorem 5.72(e) says that $x^3 - 2$ has exactly one root modulo p iff Frob_p is a transposition (density $1/2$), three roots iff $\mathrm{Frob}_p = 1$ (density $1/6$), and none iff Frob_p is a 3-cycle (density $1/3$). A transposition is odd, and the sign character cuts out $\mathbb{Q}(\sqrt{-108}) = \mathbb{Q}(\sqrt{-3})$, so "exactly one root" happens iff $\chi_{-3}(\mathrm{Frob}_p) = -1$, iff $p \equiv 2 \pmod 3$. Among the 428 primes $5 \le p < 3000$ the observed proportions are 0.516, 0.159 and 0.325.

Corollary 5.76 (Frobenius elements are dense)**.** *Let $L/\mathbb{Q}$ be a Galois extension (possibly infinite) unramified outside a finite set S of primes, and X a set of primes of density one. Then the Frobenius elements $\mathrm{Frob}_{\mathfrak{P}} \in \mathrm{Gal}(L/\mathbb{Q})$ at the primes $\mathfrak{P}$ of L above the $p \in X \setminus S$ form a dense subset of $\mathrm{Gal}(L/\mathbb{Q})$.*

Proof. A basic open set of $\mathrm{Gal}(L/\mathbb{Q})$ is $\sigma\,\mathrm{Gal}(L/K)$ with $K \subseteq L$ finite Galois over $\mathbb{Q}$ (Proposition 5.51(b)). Let C be the conjugacy class of $\sigma|_K$ in $\mathrm{Gal}(K/\mathbb{Q})$. By Theorem 5.75 the set Y of primes unramified in K with $\mathrm{Frob}_p(K/\mathbb{Q}) = C$ has density $\#C/[K:\mathbb{Q}] > 0$. The complement of $X \setminus S$ has density 0 (the complement of X has density 0 and S is finite), so $Y \cap (X \setminus S)$ has the positive density of Y, and in particular contains a prime p. As $\mathrm{Frob}_p(K/\mathbb{Q}) = C$ is the set of $\mathrm{Frob}_{\mathfrak{p}}$ for the primes $\mathfrak{p}$ of K above p, there is $\mathfrak{p}$ with $\mathrm{Frob}_{\mathfrak{p}} = \sigma|_K$; choose a prime $\mathfrak{P}$ of L above $\mathfrak{p}$ (Chapter 6). By Theorem 5.72(d), $\mathrm{Frob}_{\mathfrak{P}}$ restricts to $\mathrm{Frob}_{\mathfrak{p}} = \sigma|_K$ on K, that is $\mathrm{Frob}_{\mathfrak{P}} \in \sigma\,\mathrm{Gal}(L/K)$. □

Corollary 5.77 (Chebotarev and Brauer-Nesbitt)**.** *Let k be a finite field, $\overline{\mathbb{F}}_\ell$, or a finite extension of $\mathbb{Q}_\ell$, and $\rho_1, \rho_2 \colon G_{\mathbb{Q}} \to \mathrm{GL}_n(k)$ continuous, semisimple, and unramified outside a finite set S of primes. If $\det(X - \rho_1(\mathrm{Frob}_p)) = \det(X - \rho_2(\mathrm{Frob}_p))$ for all p in a set X of density one, $p \notin S$, then $\rho_1 \simeq \rho_2$.*

Proof. Let L be the field cut out by $\rho_1 \oplus \rho_2$, the fixed field of $\ker\rho_1 \cap \ker\rho_2$ (Proposition 5.62); it is Galois over $\mathbb{Q}$ and unramified outside S, since the inertia groups at $p \notin S$ act trivially through both ρ_i. Both ρ_i factor through $\mathrm{Gal}(L/\mathbb{Q})$. The map

$$\mathrm{Gal}(L/\mathbb{Q}) \to k^n, \qquad g \mapsto \text{coefficients of } \det(X - \rho_1(g)) - \det(X - \rho_2(g)),$$

is continuous (polynomial in the matrix entries), so its zero set is closed; it contains the Frobenius elements at the primes above $X \setminus S$, which are dense by Corollary 5.76. Hence $\rho_1(g)$ and $\rho_2(g)$ have the same characteristic polynomial for every $g \in G_{\mathbb{Q}}$. By Brauer-Nesbitt (Chapter 4, for an arbitrary group over an arbitrary field) $\rho_1^{ss} \simeq \rho_2^{ss}$, that is $\rho_1 \simeq \rho_2$ as both are semisimple. (For finite k the image is finite and the finite-group form suffices.) □

Corollary 5.78 (Congruent traces)**.** *Let $\mathcal{O}$ be the ring of integers of a finite extension of $\mathbb{Q}_\ell$, $\lambda = \varpi\mathcal{O}$ its maximal ideal, $k = \mathcal{O}/\lambda$, and $\rho_1, \rho_2 \colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathcal{O})$ continuous and unramified outside a finite set S. Suppose $\operatorname{tr}\rho_1(\mathrm{Frob}_p) \equiv \operatorname{tr}\rho_2(\mathrm{Frob}_p)$ and $\det\rho_1(\mathrm{Frob}_p) \equiv \det\rho_2(\mathrm{Frob}_p) \pmod{\lambda}$ for all p in a set of density one, $p \notin S$.*

(a) $\bar\rho_1^{ss} \simeq \bar\rho_2^{ss}$ over k.

(b) If $\bar\rho_1$ is absolutely irreducible, then $\bar\rho_2 \simeq \bar\rho_1$.

(c) Conversely, if $\bar\rho_1^{ss} \simeq \bar\rho_2^{ss}$, the congruences hold for every $p \notin S$.

(d) (Newforms; given the representations attached to newforms, Chapter 15.) Let ℓ be odd, $E/\mathbb{Q}$ an elliptic curve of conductor N with $\bar\rho_{E,\ell}$ irreducible, and h a newform of weight 2 on $\Gamma_0(M)$ (trivial character) whose coefficients lie in $\mathcal{O}$ (for a chosen embedding of its coefficient field). If $a_p(h) \equiv a_p(E) \pmod{\lambda}$ for all $p \nmid \ell MN$ in a set of density one, then $\bar\rho_h \simeq \bar\rho_{E,\ell} \otimes_{\mathbb{F}_\ell} k$, for every choice of the stable lattice defining $\bar\rho_h$.

Proof. (a) The characteristic polynomial of $\bar\rho_i(\mathrm{Frob}_p)$ is $X^2 - \operatorname{tr} X + \det$ reduced modulo λ, and it is also that of $\bar\rho_i^{ss}(\mathrm{Frob}_p)$ (characteristic polynomials are multiplicative along a composition series). The $\bar\rho_i^{ss}$ are continuous, semisimple and unramified outside S (inertia acts trivially on $\bar\rho_i$, hence on its subquotients); apply Corollary 5.77. (b) $\bar\rho_2^{ss} \simeq \bar\rho_1^{ss} = \bar\rho_1$ is irreducible of dimension 2, so the two-dimensional $\bar\rho_2$ has an irreducible composition factor of dimension 2, hence is irreducible and equal to its semisimplification. (c) Characteristic polynomials of $\bar\rho_i(\mathrm{Frob}_p)$ and of $\bar\rho_i^{ss}(\mathrm{Frob}_p)$ agree. (d) The black box of Chapter 15 gives a continuous $\rho_{h,\lambda} \colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathcal{O})$ (after choosing a stable lattice, Proposition 5.62(c)), unramified outside $M\ell$, with $\det\rho_{h,\lambda} = \chi_\ell$ and $\operatorname{tr}\rho_{h,\lambda}(\mathrm{Frob}_p) = a_p(h)$ for $p \nmid M\ell$. Take $\rho_1 = \rho_{E,\ell} \otimes_{\mathbb{Z}_\ell} \mathcal{O}$, which is unramified outside ℓN with $\det\rho_1 = \chi_\ell$ and $\operatorname{tr}\rho_1(\mathrm{Frob}_p) = a_p(E)$ for $p \nmid \ell N$ (Chapter 9, Chapter 11), and $\rho_2 = \rho_{h,\lambda}$, with S the primes dividing ℓMN. The determinants of Frobenius agree and the traces are congruent on a set of density one. Since $\bar\rho_{E,\ell}$ is irreducible and $\det\bar\rho_{E,\ell} = \bar\chi_\ell$ with ℓ odd, it is absolutely irreducible (Proposition 5.60(d)), and so is $\bar\rho_1 = \bar\rho_{E,\ell} \otimes_{\mathbb{F}_\ell} k$. By (b), $\bar\rho_h = \bar\rho_2 \simeq \bar\rho_1$; the argument applies to every stable lattice (and Proposition 5.69 gives the independence of $\bar\rho_h^{ss}$ directly). □

In the paper 5.79. Lemma lem:old, case $p \nmid \ell N$: "$\bar\rho_h \simeq \bar\rho$ over a common finite extension of $\mathbb{F}_\ell$, by Chebotarev and Brauer-Nesbitt, $\bar\rho$ being irreducible, hence absolutely irreducible". This is Corollary 5.78(d), after enlarging $\mathcal{O}$ so that it contains the coefficients of the newform h of the lemma; it rests on the black box of Chapter 15 (the representation $\rho_{h,\lambda}$ with $\operatorname{tr}\rho_{h,\lambda}(\mathrm{Frob}_p) = a_p(h)$). The two residual representations a priori live over different finite fields (k and $\mathbb{F}_\ell$), so they are compared over k, as $\bar\rho_{E,\ell} \otimes_{\mathbb{F}_\ell} k$; and "irreducible, hence absolutely irreducible" is Proposition 5.60(d). The equivalence quoted in the proof of Theorem thm:qual (Section sec:proof: "$\bar\rho_g \simeq \bar\rho$, that is, $a_p(g) \equiv a_p(f) \pmod{\lambda}$ for all $p \nmid 3N$"), and in the Example of that section, is (c) in one direction and (d) in the other.

5.10 Exercises

The exercises are graded from routine to harder. Exercises 5.91 and 5.92 check the paper's statements on the 3-division polynomial on curves not treated in the text; Exercise 5.93 generalises the determinant argument of Lemma lem:h0.

Exercise 5.80. Show that $\mathbb{Q}(\sqrt{2},\sqrt{3}) = \mathbb{Q}(\sqrt{2}+\sqrt{3})$, that the minimal polynomial of $\sqrt{2}+\sqrt{3}$ is $x^4 - 10x^2 + 1$, and list the intermediate fields with the corresponding subgroups of $\mathrm{Gal}(\mathbb{Q}(\sqrt{2},\sqrt{3})/\mathbb{Q}) \simeq V_4$. Deduce that $x^4 - 10x^2 + 1$ is irreducible over $\mathbb{Q}$ but reducible modulo every prime p. (Hint: modulo p one of 2, 3, 6 is a square, and then the polynomial factors over $\mathbb{F}_p$; compare with Proposition 5.46(c), case V_4.)

Exercise 5.81. Let $\alpha = 2^{1/4} \in \mathbb{R}$. Show that the splitting field of $x^4 - 2$ over $\mathbb{Q}$ is $\mathbb{Q}(\alpha, i)$, of degree 8, with Galois group D_4, and identify the three quadratic subfields. Show that over $\mathbb{Q}(i)$ the polynomial $x^4 - 2$ stays irreducible with cyclic Galois group of order 4 (use Proposition 5.35(c) with $n = 4$, $\mu_4 \subset \mathbb{Q}(i)$, after checking that 2 is not a square in $\mathbb{Q}(i)$). Confirm the result with Proposition 5.46(c): the resolvent cubic of $x^4 - 2$ is $y^3 + 8y = y(y^2 + 8)$.

Exercise 5.82. Let $z = \zeta_7 + \zeta_7^{-1} = 2\cos(2\pi/7)$. Show that z is a root of $x^3 + x^2 - 2x - 1$, that this cubic has discriminant 49 and roots $2\cos(2\pi k/7)$, $k = 1, 2, 3$, and that its splitting field is the real cubic subfield of $\mathbb{Q}(\zeta_7)$. Which primes p split completely in it? (Answer: $p \equiv \pm 1 \pmod 7$.)

Exercise 5.83. Let p be an odd prime and $k \geq 1$. Using $(x^{p^{k-1}} - 1)\Phi_{p^k}(x) = x^{p^k} - 1$ and the method of Proposition 5.44(e), show that

$$\mathrm{disc}(\Phi_{p^k}) = (-1)^{\varphi(p^k)/2}\, p^{\,p^{k-1}(pk-k-1)}.$$

Check the cases $p^k = 9$ (-3^9) and 25 (5^{35}). Deduce that the unique quadratic subfield of $\mathbb{Q}(\zeta_{p^k})$ is $\mathbb{Q}(\sqrt{p^*})$.

Exercise 5.84. Show that $\mathbb{Q}(\sqrt{-5}) \subseteq \mathbb{Q}(\zeta_{20})$ and $\mathbb{Q}(\sqrt{6}) \subseteq \mathbb{Q}(\zeta_{24})$. Show that if $\mathbb{Q}(\sqrt{-5}) \subseteq \mathbb{Q}(\zeta_m)$ then $20 \mid m$. (Hint: by Theorem 5.28(c), $\mathbb{Q}(\sqrt{-5}) \subseteq \mathbb{Q}(\zeta_m) \cap \mathbb{Q}(\zeta_{20}) = \mathbb{Q}(\zeta_{\gcd(m,20)})$; list the quadratic subfields of $\mathbb{Q}(\zeta_g)$ for the proper divisors g of 20.) Prove the analogous statement for $\mathbb{Q}(\sqrt{6})$ and 24.

Exercise 5.85. Prove that the degree of a splitting field of a polynomial of degree n divides $n!$. (Hint: induction on n; if f is reducible, $f = gh$, use that $\deg g!\,\deg h!$ divides $n!$; if f is irreducible, adjoin one root.)

Exercise 5.86. Let $q = p^r$ and $a \in \mathbb{F}_q$. Show that $x^p - x - a$ is irreducible over $\mathbb{F}_q$ iff $\mathrm{Tr}_{\mathbb{F}_q/\mathbb{F}_p}(a) \neq 0$. (Hint: $\wp\colon \mathbb{F}_q \to \mathbb{F}_q$ is $\mathbb{F}_p$-linear with kernel $\mathbb{F}_p$, so its image has index p; show that $\mathrm{Tr}_{\mathbb{F}_q/\mathbb{F}_p}(\wp(b)) = 0$, and compare sizes, using Proposition 5.33(d).)

Exercise 5.87. Let $u \in \mathbb{F}_{13}^\times$ and $\ell = 3$, so $v = v_3(12) = 1$. Show that u is a cube in $\mathbb{F}_{13}$ iff $u^4 = 1$, that the cubes are $\{1, 5, 8, 12\}$, and that the class of $u = 2$ in $\mathbb{F}_{13}^\times/(\mathbb{F}_{13}^\times)^3 \simeq \mu_3(\mathbb{F}_{13})$ is $2^4 = 3$. Compute $\mathrm{Frob}_{13}(\alpha)/\alpha$ for a cube root α of 2 in $\mathbb{F}_{13^3}$, and explain why $x^3 - 2$ is irreducible over $\mathbb{F}_{13}$.

Exercise 5.88. Let $\widehat{\mathbb{Z}} \simeq G_{\mathbb{F}_p}$. Show that the closed subgroups of $\widehat{\mathbb{Z}} = \prod_q \mathbb{Z}_q$ are the products $\prod_q q^{a_q}\mathbb{Z}_q$ with $a_q \in \{0, 1, 2, \ldots, \infty\}$ $(q^\infty\mathbb{Z}_q = 0)$, and that the closed subgroup topologically generated by Frob_p^n is $n\widehat{\mathbb{Z}}$. Describe the fixed fields: for instance, the union of the fields $\mathbb{F}_{p^{\ell^k}}$, $k \geq 1$, has Galois group $\mathbb{Z}_\ell$ over $\mathbb{F}_p$ and is the fixed field of $\prod_{q \neq \ell} \mathbb{Z}_q$.

Exercise 5.89. Let ℓ be odd. Show that $\chi_\ell(G_{\mathbb{Q}}) = \mathbb{Z}_\ell^\times$ is infinite, and that every neighbourhood of 1 in $\mathrm{GL}_1(\mathbb{Q}_\ell) = \mathbb{Q}_\ell^\times$ contains a nontrivial closed subgroup (namely $1 + \ell^k\mathbb{Z}_\ell$ for k large). Explain why the argument of Proposition 5.62(d) fails over $\mathbb{Q}_\ell$. Show also that a continuous homomorphism $\widehat{\mathbb{Z}} \to \mathbb{C}^\times$ is determined by the image of 1, which is a root of unity, and that every root of unity occurs.

Exercise 5.90. Let $\ell \geq 5$ and $\bar\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{F}_\ell)$ continuous and absolutely irreducible, with image contained in the normaliser $N_s(\mathbb{F}_\ell)$ of the diagonal split Cartan subgroup $C_s(\mathbb{F}_\ell)$ but not in $C_s(\mathbb{F}_\ell)$. Show: (a) the composite $G_{\mathbb{Q}} \to N_s(\mathbb{F}_\ell)/C_s(\mathbb{F}_\ell) \simeq \{\pm 1\}$ is χ_d for a unique quadratic field $\mathbb{Q}(\sqrt{d})$; (b) $\bar\rho \simeq \bar\rho \otimes \chi_d$ and $\bar\rho \simeq \mathrm{Ind}_{G_{\mathbb{Q}(\sqrt{d})}}^{G_{\mathbb{Q}}} \psi$ for a character ψ of $G_{\mathbb{Q}(\sqrt{d})}$ with values in $\mathbb{F}_\ell^\times$; (c) if $d = \ell^*$, the hypothesis of Theorem thm:main fails for $\bar\rho$, although $\bar\rho \not\simeq \bar\rho \otimes \bar\chi_\ell$.

Exercise 5.91. The paper's example 726a1 is $y^2 + xy = x^3 + x^2 - 35x - 51$, with mod 3 image 3Ns. Check with PARI (`elldivpol(E,3)`, `factor`) that

$$\psi_3 = 3x^4 + 5x^3 - 210x^2 - 612x - 1480 = (x^2 - x - 74)(3x^2 + 8x + 20),$$

that the two factors have discriminants $297 = 3^3 \cdot 11$ and $-176 = -2^4 \cdot 11$, so that $K_1 = \mathbb{Q}(\sqrt{33})$, $K_2 = \mathbb{Q}(\sqrt{-11})$ and the third quadratic subfield of K_1K_2 is $\mathbb{Q}(\sqrt{-3})$, as Proposition 5.47(e) requires. Verify that $a_p \equiv 0 \pmod 3$ for the primes $p \equiv 2 \pmod 3$, $p \nmid 726$, $p < 100$, and find the primes $p < 60$, $p \nmid 726$, at which $\psi_3 \bmod p$ splits into four distinct linear factors (answer: 31, 37). (At $p = 2$ and $p = 11$ it also splits into linear factors, with repetitions; at $p = 3$ its degree drops.)

Exercise 5.92. For 121a1, $y^2 + xy + y = x^3 + x^2 - 30x - 76$, check that $\psi_3 = 3x^4 + 5x^3 - 177x^2 - 909x - 1249$ is irreducible with $\operatorname{disc}\psi_3 = -3^3 \cdot 11^4$ and irreducible resolvent cubic, so that its group is S_4 and the image of $\bar\rho_{E,3}$ is $\mathrm{GL}_2(\mathbb{F}_3)$. With $a_{19} = -6$ and $a_{29} = -9$, predict the factorisation patterns of ψ_3 modulo 19 and 29 from Example 5.73, and verify them.

Exercise 5.93. Let ℓ be odd, $\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{Z}_\ell)$ continuous and $m \geq 1$. Show that if $\rho \bmod \ell^k \simeq (\rho \otimes \chi_\ell^m) \bmod \ell^k$ with $k \geq 1$, then $\ell^{k-1}(\ell - 1)$ divides $2m$. (Hint: $\chi_\ell^{2m} \equiv 1 \pmod{\ell^k}$ on $G_{\mathbb{Q}}$, and $(\mathbb{Z}/\ell^k)^\times$ is cyclic of order $\ell^{k-1}(\ell-1)$, Chapter 2.) Recover Proposition 5.64(c) as the case $m = 1$, and show that for $\ell = 5$, $m = 2$ the condition allows only $k = 1$.

Exercise 5.94. Using Theorem 5.72 and Theorem 5.75, show that $x^3 - 3x + 1$ has either three roots or none modulo every prime $p \neq 3$, that it has three roots iff $p \equiv \pm 1 \pmod 9$, and that the set of these primes has density $1/3$. Count the primes $5 \leq p < 3000$ with three roots (there are 142 of 428).

Exercise 5.95. Let $E/\mathbb{Q}$ be an elliptic curve with $\bar\rho_{E,5}$ surjective onto $\mathrm{GL}_2(\mathbb{F}_5)$. Compute the images of $G_{\mathbb{Q}(\sqrt{5})}$ and of $G_{\mathbb{Q}(\zeta_5)}$ under $\bar\rho_{E,5}$ and their orders (240 and 120). Show that $\bar\rho_{E,5}$ is absolutely irreducible on $G_{\mathbb{Q}(\sqrt{5})}$. (Use Proposition 5.66(c) and the fact that $\mathrm{SL}_2(\mathbb{F}_5)$ acts irreducibly on $\overline{\mathbb{F}}_5^2$, Chapter 1.)

5.11 Notes and references

The finite theory (Sections 1 to 6) follows [109, Chapters V and VI], [58, Chapters 13 and 14] and [135]; the proofs of the primitive element theorem, of Artin's theorem and of Hilbert's Theorem 90 are the classical ones. The irreducibility proof of Φ_n is Dedekind's, as in [109, Chapter VI,

Section 3] and [201, Chapter 2]; Gauss sums and $g^2 = \ell^*$ are Chapter 2 and [87, Chapter 6]. Kummer theory and Artin-Schreier theory are [109, Chapter VI, Sections 6 and 8]; Capelli's criterion is [109, Chapter VI, Section 9]. The resolvent cubic and the Galois groups of quartics are [58, Section 14.6]; the C_4 versus D_4 test is due to Kappe and Warren [90]. Infinite Galois theory and the Krull topology follow [142, Chapter IV, Section 1], [143, Chapter I, Section 1] and [135, Chapter 7]. Continuous ℓ-adic representations, lattices, the independence of $\bar{\rho}^{ss}$ from the lattice and the use of Chebotarev's theorem with Brauer-Nesbitt are in [178, Chapter I] and [38, Section 1]; the Chebotarev density theorem itself is [142, Chapter VII, Section 13], and the comparison of densities [172, Chapter VI, Section 4]. The theorem of Artin and Schreier is in [109, Chapter VI, Section 9], and the real closed fields behind the statement on elements of finite order in [109, Chapter XI]. The Kummer cocycle of a Tate parameter and its matrix form are [178, Chapter IV] and Chapter 10; its cohomological meaning is [143, Chapter VI] and Chapter 17.

The chapter and section numbers of the books cited in this chapter (Lang, Dummit-Foote, Neukirch, Neukirch-Schmidt-Wingberg, Serre, Washington, Ireland-Rosen, Milne) are pointers recalled from the editions listed in the bibliography and have not been checked against the printed books; the only theorem number given, Lang's Theorem VI.9.1 for Capelli's criterion, is unverified in the same sense. The numerical statements (discriminants, factorisations of ψ_3, Frobenius patterns, traces a_p, the subgroup table of $\mathrm{GL}_2(\mathbb{F}_3)$, the prime counts) were recomputed for this chapter with PARI/GP 2.17 through cypari2 and a short enumeration of $\mathrm{GL}_2(\mathbb{F}_3)$; the curve data agree with Cremona's tables (6912d1 and 726a1 have mod 3 image 3Ns there).

Notation: the quadratic characters χ_{q^*} are written as in the paper, and the paper's $\bar{\chi}_3^{\mathrm{cyc}}$ is the book's $\bar{\chi}_3$. Lemma lem:h0 and Section 1.3 of the paper state the exceptional case with $\bar{\chi}_\ell$; Proposition 5.64(c) and Proposition 5.29(c) are the facts behind this choice.

Chapter 6

Algebraic number theory

The paper lives over $\mathbb{Q}$, but its arguments constantly leave $\mathbb{Q}$: the coefficients of a congruent eigenform lie in a ring of integers $\mathcal{O}$ with a prime $\lambda \mid \ell$; the Galois group acts through decomposition and inertia groups and Frobenius elements; the quadratic fields $\mathbb{Q}(i)$, $\mathbb{Q}(\sqrt{-3})$, $\mathbb{Q}(\sqrt{q^*})$ and $\mathbb{Q}(\sqrt{\ell^*})$ supply the characters χ_{-4}, χ_{-3}, χ_{q^*} and χ_{ℓ^*}; and the rings $\mathbb{Z}_3[\zeta_3]$ and $\mathbb{Z}_\ell \otimes \mathbb{Z}[\zeta_3]$ carry the action of inertia at the additive primes of types IV and II. This chapter supplies that algebraic number theory, from rings of integers and unique factorisation of ideals to the splitting of primes, the Frobenius element, cyclotomic fields, the dictionary between Dirichlet characters and characters of $G_{\mathbb{Q}}$, the Chebotarev density theorem and complex multiplication. It uses Chapter 1 for group actions and profinite groups, Chapter 2 for rings, finite fields, Kronecker symbols, quadratic reciprocity and Dirichlet characters, Chapter 3 for modules over principal ideal domains and discrete valuation rings, Chapter 4 for representations, and Chapter 5 for Galois theory; local fields are in Chapter 7.

Core results at a glance

Throughout, K, L are number fields, $\mathcal{O}_K$ the ring of integers, $\mathfrak{p}$, $\mathfrak{P}$, λ nonzero primes, $N\mathfrak{p} = \#\mathcal{O}_K/\mathfrak{p}$, D the discriminant of a quadratic field and χ_D its character; $\pi = 1 - \zeta_3$; Frob is the arithmetic Frobenius and Frob^{-1} the geometric one.

6.1 Conventions. $\overline{\mathbb{Q}} \subset \mathbb{C}$, $\bar{\mathbb{Z}}$ the algebraic integers, $\zeta_n = e^{2\pi i/n}$; D is a quadratic discriminant and $D_{\mathfrak{P}}$ a decomposition group; χ_D is indexed by the fundamental discriminant (χ_{-4}, χ_{-3}, χ_8, χ_{q^*}); χ_ℓ is cyclotomic; the geometric Frobenius is written Frob_p^{-1}. Convention 6.1.

6.2 Number fields (definition): $[K : \mathbb{Q}] = n < \infty$, $K = \mathbb{Q}(\theta)$, n embeddings into $\mathbb{C}$, $n = r_1 + 2r_2$. Definition 6.2.

6.3 Algebraic integers. α is integral iff its minimal polynomial is in $\mathbb{Z}[X]$ iff $\mathbb{Z}[\alpha]$ is a finitely generated $\mathbb{Z}$-module iff α lies in a subring finitely generated as a $\mathbb{Z}$-module; $\mathcal{O}_K$ is a ring, $\mathcal{O}_K \cap \mathbb{Q} = \mathbb{Z}$, $\operatorname{Frac} \mathcal{O}_K = K$, and $\mathcal{O}_K$ is integrally closed. *(proved here)* Proposition 6.3.

6.4 Trace and norm (definition): trace and determinant of $x \mapsto \alpha x$. Definition 6.4.

6.5 Properties of trace and norm. $\mathrm{Tr}(\alpha) = \sum \sigma_i(\alpha)$, $N(\alpha) = \prod \sigma_i(\alpha)$; integers on $\mathcal{O}_K$; $\alpha \in \mathcal{O}_K^\times$ iff $N(\alpha) = \pm 1$; transitivity in towers. *(proved here)* Proposition 6.5.

6.6 Integral bases and the discriminant. The trace form is nondegenerate; $\mathcal{O}_K \simeq \mathbb{Z}^n$; $d_K = \det(\mathrm{Tr}(\beta_i\beta_j)) = \det(\sigma_k\beta_j)^2$ is independent of the basis; $\mathrm{disc}(\alpha_1,\dots,\alpha_n) = [\mathcal{O}_K : \sum \mathbb{Z}\alpha_i]^2 d_K$; $\mathrm{disc}(1,\theta,\dots,\theta^{n-1}) = \mathrm{disc}(g) = (-1)^{n(n-1)/2}N(g'(\theta))$. *(proved here)* Theorem 6.6.

6.7 Quadratic fields. For d squarefree, $\mathcal{O} = \mathbb{Z}[\sqrt{d}]$, $d_K = 4d$ if $d \equiv 2,3 \pmod 4$, and $\mathcal{O} = \mathbb{Z}[\frac{1+\sqrt{d}}{2}]$, $d_K = d$ if $d \equiv 1 \pmod 4$; quadratic fields correspond to fundamental discriminants; $\mathbb{Z}[i]$ ($D=-4$), $\mathbb{Z}[\zeta_3]$ ($D=-3$). *(proved here)* Proposition 6.7.

6.8 Units. (i) $\mathcal{O}_K^\times \simeq \mu(K)\times\mathbb{Z}^{r_1+r_2-1}$ *(stated; reference)*; (ii) for K imaginary quadratic $\mathcal{O}_K^\times = \mu(K)$, which is $\{\pm1\}$ except μ_4 for $\mathbb{Q}(i)$ and μ_6 for $\mathbb{Q}(\sqrt{-3})$; (iii) $\mathbb{Z}[\sqrt{2}]^\times = \pm(1+\sqrt{2})^{\mathbb{Z}}$ *((ii), (iii) proved here).* Theorem 6.9.

6.9 Dedekind domains (definition): Noetherian, integrally closed, not a field, nonzero primes maximal. Definition 6.10.

6.10 $\mathcal{O}_K$ is a Dedekind domain; $\mathfrak{p}\cap\mathbb{Z} = p\mathbb{Z}$ and $\mathcal{O}_K/\mathfrak{p}$ is a finite field; PIDs (not fields) are Dedekind; a Noetherian domain (not a field) is Dedekind iff all its localisations at nonzero primes are discrete valuation rings. *(proved here)* Theorem 6.11.

6.11 Inverse of a prime. Every nonzero ideal contains a product of primes; $\mathfrak{p}^{-1} = \{x : x\mathfrak{p} \subseteq R\}$ satisfies $\mathfrak{a}\mathfrak{p}^{-1} \neq \mathfrak{a}$ and $\mathfrak{p}\mathfrak{p}^{-1} = R$. *(proved here)* Lemma 6.12.

6.12 Unique factorisation of ideals. In a Dedekind domain every nonzero proper ideal is uniquely a product of primes; fractional ideals form a group, free on the primes; to divide is to contain; $v_\mathfrak{p}$ is a discrete valuation. *(proved here)* Theorem 6.13.

6.13 Norm of an ideal. $N\mathfrak{a} = \#\mathcal{O}_K/\mathfrak{a}$ is multiplicative, $N(\alpha) = |N_{K/\mathbb{Q}}\alpha|$, $N\mathfrak{p} = p^f$ with $\mathcal{O}_K/\mathfrak{p} \simeq \mathbb{F}_{p^f}$, $\mathfrak{p}^k/\mathfrak{p}^{k+1} \simeq \mathcal{O}_K/\mathfrak{p}$; ideals of prime norm are prime; disc of a basis of $\mathfrak{a}$ is $(N\mathfrak{a})^2 d_K$. *(proved here)* Proposition 6.14.

6.14 Chinese remainder theorem, two generators, localisation. $R/\mathfrak{a} \simeq \prod R/\mathfrak{p}_i^{a_i}$; every ideal is (α,β) with α arbitrary; finitely many primes implies PID; UFD iff PID; $R_\mathfrak{p}$ is a discrete valuation ring with residue field $R/\mathfrak{p}$ and valuation $v_\mathfrak{p}$. *(proved here)* Proposition 6.15.

6.15 Class group. $\mathrm{Cl}(K) = J_K/P_K$; $h_K = 1$ iff PID iff UFD *(proved here)*; Minkowski: $\mathrm{Cl}(K)$ is finite, each class contains an ideal of norm $\le (4/\pi)^{r_2}(n!/n^n)|d_K|^{1/2}$, and $|d_K| > 1$ for $K \neq \mathbb{Q}$ *(stated; reference)*. Examples: $h = 1$ for $D = -3,-4,-7,5,8,-11$, $h = 2$ for $D = -20$. Theorem 6.16.

6.16 $\sum e_i f_i = n$. $\mathfrak{p}\mathcal{O}_L = \prod \mathfrak{P}_i^{e_i}$ with residue degrees f_i satisfies $\sum e_i f_i = [L:K]$; ramified, inert, split; e and f are multiplicative in towers. *(proved here)* Theorem 6.19.

6.17 Dedekind-Kummer. If $p \nmid [\mathcal{O}_K : \mathbb{Z}[\theta]]$ and $g \equiv \prod \bar{g}_i^{e_i} \pmod p$, then $p\mathcal{O}_K = \prod (p, g_i(\theta))^{e_i}$ with $f_i = \deg \bar{g}_i$ *(proved here)*; relative version *(stated; reference)*. Theorem 6.20.

6.18 Dedekind's discriminant theorem. p ramifies in K iff $p \mid d_K$ *(proved here)*; relative version *(stated; reference)*. Theorem 6.22.

6.19 Decomposition and inertia groups. For L/K Galois, G is transitive on the primes above $\mathfrak{p}$; $efg = n$; $D_\mathfrak{P}$ is the stabiliser, $\#D_\mathfrak{P} = ef$, $I_\mathfrak{P} \trianglelefteq D_\mathfrak{P}$, both conjugate along the orbit. *(proved here)* Proposition 6.23.

6.20 Residue field extension. $D_{\mathfrak{P}} \to \mathrm{Gal}(\kappa(\mathfrak{P})/\kappa(\mathfrak{p}))$ is surjective with kernel $I_{\mathfrak{P}}$, so $\#I_{\mathfrak{P}} = e$ and D/I is cyclic of order f; behaviour in towers; split completely iff $D = 1$, unramified iff $I = 1$. *(proved here)* Theorem 6.24.

6.21 Arithmetic and geometric Frobenius (convention): Frob_p is arithmetic, $\chi_\ell(\mathrm{Frob}_p) = p$; $L_p(V, s) = \det(1 - \mathrm{Frob}_p^{-1}\, p^{-s} \mid V^{I_p})^{-1}$; the two conventions agree when the eigenvalues are inversion-stable, and differ at a multiplicative prime, where only the geometric one gives $1 - q^{-1-s}$. Convention 6.25, Example 6.26.

6.22 The Frobenius element. For $\mathfrak{p}$ unramified there is a unique $\mathrm{Frob}_{\mathfrak{P}}$ with $\mathrm{Frob}_{\mathfrak{P}}(x) \equiv x^{N\mathfrak{p}} \pmod{\mathfrak{P}}$; it generates $D_{\mathfrak{P}}$; its conjugacy class is $\mathrm{Frob}_{\mathfrak{p}}$; it is 1 iff $\mathfrak{p}$ splits completely; functoriality; at ramified primes only a coset of inertia. *(proved here)* Proposition 6.27.

6.23 Frobenius and subfields. For $M = L^H$, the primes of M above p correspond to the $\langle \mathrm{Frob}_{\mathfrak{P}} \rangle$-orbits on G/H, with residue degrees the orbit lengths. *(proved here)* Proposition 6.28.

6.24 Dedekind's theorem on cycle types. If $p \nmid a\,\mathrm{disc}(f)$, p is unramified in the splitting field of f and $\mathrm{Frob}_{\mathfrak{P}}$ permutes the roots with cycle type the degrees of the irreducible factors of f mod p. *(proved here)* Corollary 6.29.

6.25 Frobenius elements in $G_{\mathbb{Q}}$. Primes of $\bar{\mathbb{Z}}$ above p; D_p, I_p closed, conjugate, with $1 \to I_p \to D_p \to \mathrm{Gal}(\overline{\mathbb{F}}_p/\mathbb{F}_p) \to 1$ exact and surjective projections to finite levels; Frob_p defined up to I_p and conjugation; unramified representations and $\rho(\mathrm{Frob}_p)$ *(proved here)*; $D_p \simeq G_{\mathbb{Q}_p}$ *(stated; Chapter 7)*. Proposition 6.30.

6.26 Tame inertia. If $\#I_{\mathfrak{P}}$ is prime to p, $I_{\mathfrak{P}}$ is cyclic and $F\tau F^{-1} = \tau^{N\mathfrak{p}}$ for every Frobenius F and $\tau \in I_{\mathfrak{P}}$. *(proof sketched here; proved in Chapter 7)* Proposition 6.31.

6.27 Frobenius on a tame image of inertia. For $\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{Z}_\ell)$, ℓ odd, $\ell \neq q$, with $\rho(I_q)$ finite of order prime to q: $\rho(I_q)$ is cyclic and $\rho(F)\rho(\tau)\rho(F)^{-1} = \rho(\tau)^q$; so Frobenius centralises or inverts an element of order 3 according as $q \equiv 1$ or $2 \pmod 3$, and one of order 4 according as $q \equiv 1$ or $3 \pmod 4$. *(proved here, given Proposition 6.31)* Corollary 6.32.

6.28 Splitting in quadratic fields. p ramifies, splits or is inert in $\mathbb{Q}(\sqrt{d})$ according as $(\frac{D}{p}) = 0, 1, -1$, with explicit primes, including $p = 2$. *(proved here)* Theorem 6.34.

6.29 The character of a quadratic field. $\chi_D(\mathrm{Frob}_p) = (\frac{D}{p})$ for $p \nmid D$; χ_D is ramified exactly at $p \mid D$; $\chi_{-4}(\mathrm{Frob}_p) = (-1)^{(p-1)/2}$, $\chi_{-3}(\mathrm{Frob}_p) = 1$ iff $p \equiv 1 \pmod 3$, $\chi_{q^*}(\mathrm{Frob}_p) = (\frac{p}{q})$ for $p \neq q$ including $p = 2$. *(proved here)* Proposition 6.35.

6.30 Ramified only at q. $\mathbb{Q}(\sqrt{q^*})$ is the unique quadratic field ramified only at the odd prime q; fundamental discriminants are products of prime discriminants; $\chi_S = \prod_{q \in S} \chi_{q^*}$ is the character of $\mathbb{Q}(\sqrt{\prod q^*})$, of conductor $\prod q$, ramified exactly at S. *(proved here)* Proposition 6.36.

6.31 Gaussian and Eisenstein primes. $\mathbb{Z}[i]$, $\mathbb{Z}[\zeta_3]$ are PIDs; their primes are $1 + i$, $a \pm bi$ ($p = a^2 + b^2 \equiv 1 \bmod 4$), $p \equiv 3 \pmod 4$; resp. $1 - \zeta_3$, $a + b\zeta_3^{\pm 1}$ ($p = a^2 - ab + b^2 \equiv 1 \bmod 3$), $p \equiv 2 \pmod 3$. *(proved here)* Proposition 6.38.

6.32 The prime above 3. $\sqrt{-3} = 1 + 2\zeta_3 = \zeta_3\pi$, $\pi^2 = -3\zeta_3$, $3 = -\zeta_3^2\pi^2$; $\mathbb{Z}[\zeta_3]/(\pi) = \mathbb{F}_3$; on $\mathbb{Z}[\zeta_3]/(\pi^2)$ multiplication by $\zeta_3 = 1 - \pi$ is a nontrivial unipotent with fixed line $(\pi)/(\pi^2)$; at 2 in $\mathbb{Z}[i]$, $(2) = (1+i)^2$ and i acts unipotently on $\mathbb{Z}[i]/(2)$. *(proved here)* Proposition 6.39.

6.33 Quadratic algebras over $\mathbb{Z}_\ell$. $\mathbb{Z}_\ell[X]/(g)$ is an unramified discrete valuation ring if $\bar{g}$ is irreducible, a ramified one with uniformiser $x - c$ if $g(X + c)$ is Eisenstein, and $\mathbb{Z}_\ell \times \mathbb{Z}_\ell$ if $\bar{g}$ has distinct roots; lattices T with $T \otimes \mathbb{Q}_\ell \simeq R \otimes \mathbb{Q}_\ell$ are free of rank one. *(proved here)* Lemma 6.40.

6.34 $\mathbb{Z}_3[\zeta_3]$. $\mathbb{Z}_3[X]/(X^2 + X + 1)$ is a discrete valuation ring with uniformiser $\pi = 1 - \zeta_3$ and residue field $\mathbb{F}_3$, $3 = \pi^2 \cdot$unit, and it is $\mathbb{Z}_3 \otimes \mathbb{Z}[\zeta_3]$ *(proved here)*; it is the ring of integers of $\mathbb{Q}_3(\sqrt{-3})$ *(stated; Chapter 7)*. Theorem 6.41.

6.35 The lattice of Lemma lem:IV. If $\sigma \in \mathrm{Aut}_{\mathbb{Z}_3}(\mathbb{Z}_3^2)$ satisfies $\sigma^2 + \sigma + 1 = 0$, then $T = \mathbb{Z}_3^2$ is free of rank one over $\mathbb{Z}_3[\sigma] \simeq \mathbb{Z}_3[\zeta_3]$, $T/3T \simeq \mathbb{Z}_3[\zeta_3]/(\pi^2)$ with σ a nontrivial unipotent fixing the line $\pi T/3T$, and $T^\sigma = 0$. *(proved here)* Corollary 6.42.

6.36 $\mathbb{Z}_\ell[\zeta_3]$ and $\mathbb{Z}_\ell[i]$. $\mathbb{Z}_\ell[\zeta_3] := \mathbb{Z}_\ell[X]/(X^2 + X + 1)$ is ramified for $\ell = 3$, $\simeq \mathbb{Z}_\ell \times \mathbb{Z}_\ell$ (not a domain) for $\ell \equiv 1 \pmod 3$, an unramified discrete valuation ring for $\ell \equiv 2 \pmod 3$; likewise $\mathbb{Z}_\ell[i]$ according to $\ell \bmod 4$; $\zeta_3 \mapsto \zeta_3^2$ negates $\sqrt{-3}$, a unit iff $\ell \neq 3$. *(proved here)* Proposition 6.43.

6.37 Lattices with an automorphism of order 3, 4, 6. For ℓ odd and $g \in \mathrm{Aut}(\mathbb{Z}_\ell^2)$ with characteristic polynomial Φ_m, $m \in \{3, 4, 6\}$ (e.g. $g \in \mathrm{SL}_2(\mathbb{Z}_\ell)$ of order m): $\mathbb{Z}_\ell[g] \simeq \mathbb{Z}_\ell[X]/(\Phi_m)$, the lattice is free of rank one over it, and the commutant of g is $\mathbb{Z}_\ell[g]$. *(proved here)* Proposition 6.44.

6.38 The commutant and the invariant line. For σ with characteristic polynomial X^2+X+1 on a plane over a field F of characteristic 0: the commutant is $F[\sigma] \simeq F \otimes \mathbb{Q}(\zeta_3)$, its trace-zero part is $F(2\sigma + 1)$ with $(2\sigma + 1)^2 = -3$, and $A\sigma A^{-1} = \sigma^q$, $q \neq 3$ prime, makes $A^{\pm 1}$ act on it by $\chi_{-3}(q)$; for τ with characteristic polynomial $X^2 + 1$ (for example of order 4 in SL_2) and q an odd prime, the line $F\tau$ and $\chi_{-4}(q)$; integrally, for ℓ odd, $\mathrm{End}_{\langle\sigma\rangle}(T) = \mathbb{Z}_\ell[\sigma] \simeq \mathbb{Z}_\ell \otimes \mathbb{Z}[\zeta_3]$. *(proved here)* Proposition 6.45.

6.39 Cyclotomic integers. $\mathcal{O} = \mathbb{Z}[\zeta_n]$; for $n = \ell^a$, $\ell = u(1-\zeta)^{\varphi(\ell^a)}$ is totally ramified; the discriminant formula; p ramifies in $\mathbb{Q}(\zeta_n)$ iff $p \mid n$ ($n \not\equiv 2 \bmod 4$). *((i), (ii) proved here for prime powers, (iii) for odd primes, (iv) in general; the rest stated with reference)* Theorem 6.48.

6.40 Splitting in cyclotomic fields. For $n = p^a m$: $e = \varphi(p^a)$, $f =$ order of p modulo m, $g = \varphi(m)/f$; inertia $(\mathbb{Z}/p^a)^\times \times 1$, decomposition $(\mathbb{Z}/p^a)^\times \times \langle p\rangle$; $\mathrm{Frob}_p = \sigma_p$ for $p \nmid n$. *(proved here)* Theorem 6.49.

6.41 $\mathbb{Q}(\sqrt{\ell^*})$. The quadratic subfield of $\mathbb{Q}(\zeta_\ell)$, ramified only at ℓ; $\chi_{\ell^*}(\mathrm{Frob}_p) = \left(\frac{p}{\ell}\right)$ for all $p \neq \ell$; imaginary iff $\ell \equiv 3 \pmod 4$. *(proved here)* Proposition 6.51.

6.42 Quadratic reciprocity, with both supplements, from Proposition 6.35 and Proposition 6.51. *(proved here)* Corollary 6.52.

6.43 Kronecker-Weber. Every abelian $K/\mathbb{Q}$ lies in some $\mathbb{Q}(\zeta_n)$; conductor; $G_{\mathbb{Q}}^{\mathrm{ab}} \simeq \hat{\mathbb{Z}}^\times$. *(stated; reference)* Theorem 6.53.

6.44 Artin map over $\mathbb{Q}$. For $K \subseteq \mathbb{Q}(\zeta_n)$, $\mathrm{Frob}_p(K/\mathbb{Q}) = \sigma_p|_K$ depends only on $p \bmod n$ *(proved here)*; idelic form and its sign conventions *(stated; reference)*. Theorem 6.54.

6.45 Dirichlet characters and characters of $G_\mathbb{Q}$. $\chi \mapsto \psi_\chi$, $\psi_\chi(\mathrm{Frob}_p) = \chi(p)$, is a bijection from primitive Dirichlet characters to continuous characters of $G_\mathbb{Q}$; ramification and conductor match; χ_ℓ and $\bar{\chi}_\ell = \psi_{\omega_\ell}$ *(proved here, given Kronecker-Weber and Chebotarev)*; twisting newforms *(stated; Chapter 13)*. Theorem 6.55.

6.46 Dedekind zeta and densities. ζ_K converges for $\mathrm{Re}\, s > 1$ *(proved here)*; simple pole at 1 *(stated; reference)*; Dirichlet density; primes of degree one have density one *(proved here, given the pole)*. Proposition 6.59.

6.47 Chebotarev. For L/K Galois and a class C, the primes with $\mathrm{Frob}_\mathfrak{p} = C$ have density $\#C/\#G$. *(stated; reference)* Theorem 6.60.

6.48 Consequences of Chebotarev. Every element is a Frobenius; split primes have density $1/[L : K]$; Bauer's theorem; Dirichlet's theorem; inert primes of $\mathbb{Q}(\sqrt{\ell^*})$ have density $\frac{1}{2}$. *(proved here, given Theorem 6.60)* Corollary 6.61.

6.49 Detecting a quadratic twist. For ρ semisimple, unramified outside S, in characteristic $\neq 2$: $\rho \simeq \rho \otimes \chi_K$ iff $\mathrm{tr}\,\rho(\mathrm{Frob}_p) = 0$ for the primes $p \notin S$ inert in K (outside density zero). *(proved here, given Chapter 5)* Proposition 6.62.

6.50 Complex multiplication. For $E/\mathbb{Q}$ with CM by K: class number one, 13 values of j *(stated; reference)*; $\rho \simeq \rho \otimes \chi_K$, $a_p = 0$ at good inert primes, and primes ramified in K are bad *(proof sketched here)*; conversely $a_p = 0$ at almost all inert primes forces CM by K, and without CM $\{p : a_p = 0\}$ has density 0 *(stated; reference)*; so CM by $\mathbb{Q}(\sqrt{\ell^*})$ forces $\ell \mid N$. Theorem 6.63.

6.51 Coefficient fields. The image of a ring finite over $\mathbb{Z}$ in $\mathbb{C}$ is an order in a number field; K_f is a number field and $a_n(f) \in \mathcal{O}_{K_f}$ *(proved here)*; conjugates are newforms, K_f totally real *(stated; Chapter 13)*. Proposition 6.66.

6.52 Primes above ℓ. Reduction modulo λ; congruences of integers modulo λ and ℓ; enlarging $\mathcal{O}$ and λ; lying over for $\mathcal{O}[\alpha]$; the root of $X^2 - aX + p$ congruent to a given root modulo a prime above λ. *(proved here)* Proposition 6.67.

6.53 Maximal ideals from congruences. $\ker(R \to \mathcal{O} \to \mathcal{O}/\lambda)$ is maximal of residue characteristic ℓ, the same for congruent homomorphisms, and an ideal J inside it with $R/J \simeq \mathbb{Z}/r$ has $\ell \mid r$ *(proved here)*; $R \otimes \mathbb{Z}_\ell = \prod R_\mathfrak{m}$ *(stated; Chapter 3)*. Proposition 6.68.

6.54 $\mathcal{O}_K \otimes \mathbb{Z}_\ell = \prod_{\lambda|\ell} \mathcal{O}_{K,\lambda}$, each a complete discrete valuation ring of rank $e_\lambda f_\lambda$ over $\mathbb{Z}_\ell$. *(stated; Chapter 7)* Proposition 6.69.

Where the paper uses this chapter

- **Lemma lem:IV** (types IV, IV* at $q \neq 3$): $\mathbb{Z}_3[\zeta_3]$ a discrete valuation ring with uniformiser π, Theorem 6.41; T_3E free of rank one over it and $E[3] \simeq \mathbb{Z}_3[\zeta_3]/(\pi^2)$ with a unipotent action, Corollary 6.42, Proposition 6.39; Frobenius conjugating σ to $\sigma^q = \sigma^{\chi_{-3}(q)}$, Corollary 6.32, Proposition 6.35; the line of $\mathrm{ad}^0 V$ and its sign, Proposition 6.45.

- **Lemma lem:euler** (the omitted factors at tame primes) **and the table of Section 1**: the tame relation, Proposition 6.31, Corollary 6.32; $\mathrm{End}_{I_q}(T) = \mathbb{Z}_\ell[\sigma] \simeq \mathbb{Z}_\ell \otimes \mathbb{Z}[\zeta_3]$, not a field for $\ell \equiv 1 \pmod 3$, Proposition 6.43, Proposition 6.44, Proposition 6.45; $\chi_{-3}(q)$, $\chi_{-4}(q)$, Proposition 6.35, Example 6.56; the geometric Frobenius in $L_q(A_f, s)$ and the row I_n, Convention 6.25, Example 6.26.

- **Section 1.1** (the local terms): I_p, Frob_p, V^{I_p}, Proposition 6.30; $L_p(A_f, s) = \det(1 - \mathrm{Frob}_p^{-1}\, p^{-s} \mid A_f^{I_p})^{-1}$, Convention 6.25. **Lemma lem:fpr**: $L_p(A_f, 1) = L_p(A_f(1), 0)$, Convention 6.25. **Lemma lem:tamfactor**: the arithmetic Frobenius, with $\mathrm{Frob}^{-1}\, t\, \mathrm{Frob} = t^{q^{-1}}$ on tame inertia, Convention 6.25, Proposition 6.31.

- **Section 1.4, Lemma lem:twist, Theorems thm:twist and thm:quant**: χ_{q^*}, the character of conductor q of $\mathbb{Q}(\sqrt{q^*})$, ramified only at q, Proposition 6.36, Proposition 6.35, Corollary 6.52; χ_S and its conductor $\prod_{q \in S} q$ (the paper's D), Proposition 6.36(iii); characters as Dirichlet and as Galois characters, Theorem 6.55, Example 6.56.

- **Theorem thm:main** (the hypothesis on $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{\ell^*}))$): $\mathbb{Q}(\sqrt{\ell^*}) \subseteq \mathbb{Q}(\zeta_\ell)$ and its splitting law, Proposition 6.51; the condition $\bar\rho \simeq \bar\rho \otimes \chi_{\ell^*}$ (reached in the paper by Clifford theory, Chapter 4; its trace form Proposition 6.62 is not used by the paper), Warning 6.57.

- **Lemma lem:h0 and Proposition prop:ns**: $\bar\chi_3^{\mathrm{cyc}} = \chi_{-3}$ and $\chi_{\ell^*} \neq \bar\chi_\ell$ for $\ell \geq 5$, Example 6.56, Warning 6.57; the isomorphism $\bar\rho \simeq \bar\rho \otimes \chi_{-3}$ comes from induction from $\mathbb{Q}(\sqrt{-3})$, $\bar\rho \otimes \overline{\mathbb{F}}_3 \simeq \mathrm{Ind}\, \psi$ with $\mathrm{Ind}\, \psi \otimes \chi_{-3} \simeq \mathrm{Ind}\, \psi$ (Chapter 4), not from Frobenius traces; Proposition 6.62 gives the equivalent trace criterion ($3 \mid a_p$ for almost all $p \equiv 2 \pmod 3$), which the book uses in an example of Chapter 5 and the paper does not use. Lemma lem:h0 holds "for every E, with or without complex multiplication", and its proof uses neither complex multiplication nor $a_p = 0$ at inert primes (Theorem 6.63, Corollary 6.61, Paper link 6.65).

- **Proposition prop:Sf**: Clifford theory for $\bar\rho|_{G_K}$, $K = \mathbb{Q}(\sqrt{\ell^*})$ (Chapter 4), and the restriction to I_ℓ of $\chi_{\ell^*} = \bar\chi_\ell^{(\ell-1)/2}$, a power of $\bar\chi_\ell|_{I_\ell}$ (the paper's fundamental character ω of level one), Example 6.56, Warning 6.57.

- **Proposition prop:ns-structure**(ii) and (iii): the trace-zero commutant of an element τ of order 4 of $\rho(I_p)$ is the line $F\tau$, on which Frobenius acts by ± 1, Proposition 6.45(iv); in (iii) the tame relation $\tau \mapsto \tau^p$ (Corollary 6.32) makes the sign $\chi_{-4}(p)$, and $\chi_{-4}(p) = \chi_{-3}(p)$ iff $p \equiv \pm 1 \pmod{12}$, Proposition 6.35(iii).

- **Lemma lem:tamadd** (potentially good primes, $\ell = 3$): T free of rank one over $\mathbb{Z}_3[X]/(X^2 + X + 1)$, with X acting as an element σ of order 3 of $\rho(I_q)$, at every $q \neq 3$, $q = 2$ included, Corollary 6.42(i), and the basis in which σ is the companion matrix, Paper link 6.46.

- **Proposition prop:forms**: $q \equiv \chi_{-3}(q) \pmod 3$ for $q \neq 3$, Proposition 6.35(iii).

- **Lemma lem:crit** (congruence criterion): coefficients in the ring of integers $\mathcal{O}$ of a number field, Proposition 6.66; $\lambda \mid \ell$ and the maximal ideal of residue characteristic ℓ, $\ell \mid r$, Proposition 6.67, Proposition 6.68; over $\mathbb{Z}_\ell$, Proposition 6.69.

- **Lemma lem:old** (oldforms): Frobenius at unramified primes and Chebotarev, Proposition 6.27, Proposition 6.30, Theorem 6.60; "after enlarging $\mathcal{O}$ and λ" and "a prime above λ in $\mathcal{O}[\alpha_p]$", Proposition 6.67(iii) to (v).

- **Section 3 and Example ex:qual**: the twisting fields $\mathbb{Q}(\sqrt{-7})$, $\mathbb{Q}(\sqrt{-11})$, Example 6.37; the congruences $a_p(g) \equiv a_p(f) \pmod{\lambda}$ at all $p \nmid 3N$ are traces of Frobenius of $\bar{\rho}_g \simeq \bar{\rho}$, Proposition 6.30(iv) (Chebotarev is needed only for the converse, as in Lemma lem:old).

6.1 Number fields and their rings of integers

This section sets up the objects behind every "$\mathcal{O}$" and every "prime $\lambda \mid \ell$" of the paper: number fields, their rings of integers, traces and norms, integral bases and the discriminant, and the units. The paper's Lemmas lem:crit and lem:old take the coefficients of a newform in the ring of integers $\mathcal{O}$ of a number field; Lemma lem:IV and Lemma lem:euler work inside $\mathbb{Z}[\zeta_3]$ and $\mathbb{Z}[i]$, the rings of integers of $\mathbb{Q}(\sqrt{-3})$ and $\mathbb{Q}(i)$, whose discriminants -3 and -4 name the characters χ_{-3} and χ_{-4} of the table of Section 1. Nothing here is specific to elliptic curves.

Convention 6.1. (a) We fix an algebraic closure $\overline{\mathbb{Q}}$ of $\mathbb{Q}$ inside $\mathbb{C}$ (as in Chapter 5); every number field is a subfield of $\overline{\mathbb{Q}}$, and $\bar{\mathbb{Z}}$ denotes the ring of all algebraic integers of $\overline{\mathbb{Q}}$. We write $\zeta_n = e^{2\pi i/n}$, and $\zeta_3 = (-1+\sqrt{-3})/2$. (b) The letters p, q, ℓ denote rational primes, as in the paper (ℓ the coefficient prime, q a bad prime of E); the size of a residue field is written $N\mathfrak{p}$, never q. Uniformisers of discrete valuation rings are written ϖ; the element $\pi = 1-\zeta_3$ of $\mathbb{Z}[\zeta_3]$ (written $1-\zeta_3$ in the paper) is the one exception, and in Section 6.4 the letter π means nothing else. (c) D denotes the discriminant of a quadratic field, and $D_{\mathfrak{P}}$, D_p decomposition groups; no other meaning of D occurs. The paper's D of Theorem thm:twist, the conductor of χ_S, is written out here as $\prod_{q\in S} q$. (d) The quadratic character of a quadratic field K of discriminant D is written χ_D (convention B-C6 of Appendix B): χ_{-4} for $\mathbb{Q}(i)$, χ_{-3} for $\mathbb{Q}(\sqrt{-3})$, χ_8 for $\mathbb{Q}(\sqrt{2})$, χ_{q^*} for $\mathbb{Q}(\sqrt{q^*})$; the index is always a fundamental discriminant, and χ_ℓ with a letter index is the ℓ-adic cyclotomic character. (e) Frob is the arithmetic Frobenius and Frob^{-1} the geometric one (Convention 6.25). Since the cyclotomic polynomials are written Φ_n in this chapter, the geometric Frobenius is always written Frob_p^{-1} here (Appendix B also writes it Φ_p).

Definition 6.2. A *number field* is a field $K \supseteq \mathbb{Q}$ with $n = [K:\mathbb{Q}] < \infty$. By the primitive element theorem (Chapter 5) $K = \mathbb{Q}(\theta)$ for some θ, and there are exactly n field embeddings $\sigma_1, \dots, \sigma_n \colon K \to \mathbb{C}$, sending θ to the n roots of its minimal polynomial. If r_1 of them have image in $\mathbb{R}$, the other $2r_2$ come in complex conjugate pairs and $n = r_1 + 2r_2$. The field is *totally real* if $r_2 = 0$ and *imaginary quadratic* if $n = 2$ and $r_1 = 0$.

Proposition 6.3 (algebraic integers)**.** *Let K be a number field and $\alpha \in K$. The following are equivalent, and α is then called an* algebraic integer*: (o) α is a root of a monic polynomial in $\mathbb{Z}[X]$; (i) the minimal polynomial of α over $\mathbb{Q}$ lies in $\mathbb{Z}[X]$; (ii) $\mathbb{Z}[\alpha]$ is a finitely generated $\mathbb{Z}$-module; (iii) α lies in a subring of K that is finitely generated as a $\mathbb{Z}$-module. The algebraic integers of K form a subring $\mathcal{O}_K$, the* ring of integers*; $\mathcal{O}_K \cap \mathbb{Q} = \mathbb{Z}$; for every $\alpha \in K$ there is an integer $m \geq 1$ with $m\alpha \in \mathcal{O}_K$, so $\mathrm{Frac}(\mathcal{O}_K) = K$; and $\mathcal{O}_K$ is* integrally closed *in K: an element of K that is a root of a monic polynomial with coefficients in $\mathcal{O}_K$ lies in $\mathcal{O}_K$.*

Proof. (o)⇒(i): if α is a root of a monic $g \in \mathbb{Z}[X]$, its minimal polynomial m_α divides g in $\mathbb{Q}[X]$, and a monic factor in $\mathbb{Q}[X]$ of a monic polynomial of $\mathbb{Z}[X]$ lies in $\mathbb{Z}[X]$ by Gauss's lemma (Chapter 2). (i)⇒(ii): if $m_\alpha \in \mathbb{Z}[X]$ is monic of degree d, division by m_α shows $\mathbb{Z}[\alpha] = \mathbb{Z} + \mathbb{Z}\alpha + \cdots + \mathbb{Z}\alpha^{d-1}$. (ii)⇒(iii) is trivial. (iii)⇒(o): let $M \ni \alpha$ be a subring generated as a $\mathbb{Z}$-module by $m_1, \dots, m_r$. Write $\alpha m_i = \sum_j a_{ij} m_j$ with $a_{ij} \in \mathbb{Z}$, so $(\alpha I - A)\underline{m} = 0$ for $A = (a_{ij})$

and the column $\underline{m}$. Multiplying by the adjugate of $\alpha I - A$ gives $\det(\alpha I - A)m_i = 0$ for all i; as $1 \in M$ is a $\mathbb{Z}$-combination of the m_i, $\det(\alpha I - A) = 0$, and $\det(XI - A)$ is monic in $\mathbb{Z}[X]$.

If α, β are algebraic integers, roots of monic integer polynomials of degrees a and b, the ring $\mathbb{Z}[\alpha, \beta]$ is generated as a $\mathbb{Z}$-module by the $\alpha^i\beta^j$, $i < a$, $j < b$ (every element is a $\mathbb{Z}$-combination of monomials $\alpha^r\beta^s$, and the monic equation of degree a rewrites α^a, hence by induction every α^r with $r \geq a$, as a $\mathbb{Z}$-combination of $1, \alpha, \dots, \alpha^{a-1}$; likewise for β); it contains $\alpha \pm \beta$ and $\alpha\beta$, which are therefore integral by (iii). A rational root $x = u/v$ (in lowest terms) of a monic $X^d + c_{d-1}X^{d-1} + \cdots + c_0 \in \mathbb{Z}[X]$ satisfies $u^d = -v(c_{d-1}u^{d-1} + \cdots + c_0v^{d-1})$, so $v \mid u^d$ and $v = \pm 1$: hence $\mathcal{O}_K \cap \mathbb{Q} = \mathbb{Z}$. If α is a root of $a_dX^d + \cdots + a_0 \in \mathbb{Z}[X]$ with $a_d \neq 0$, then $a_d\alpha$ is a root of the monic polynomial $X^d + a_{d-1}X^{d-1} + a_{d-2}a_dX^{d-2} + \cdots + a_0a_d^{d-1}$. Finally, if $x \in K$ satisfies $x^d + c_{d-1}x^{d-1} + \cdots + c_0 = 0$ with $c_i \in \mathcal{O}_K$, then $\mathbb{Z}[c_0, \dots, c_{d-1}, x]$ is a finitely generated $\mathbb{Z}$-module (each c_i is integral, and powers of x beyond x^{d-1} are reduced by the equation), so $x \in \mathcal{O}_K$ by (iii). □

Definition 6.4. For $\alpha \in K$ let $m_\alpha \colon K \to K$, $x \mapsto \alpha x$, a $\mathbb{Q}$-linear map. The *trace* and *norm* of α are $\mathrm{Tr}_{K/\mathbb{Q}}(\alpha) = \mathrm{tr}(m_\alpha)$ and $N_{K/\mathbb{Q}}(\alpha) = \det(m_\alpha)$. For a tower $L \supseteq K$ of number fields, $\mathrm{Tr}_{L/K}$ and $N_{L/K}$ are defined in the same way with L viewed as a K-vector space.

The trace and the norm turn an element of K into rational numbers by linear algebra, without choosing an embedding into $\mathbb{C}$; this is what makes them useful for integrality questions. For example, in $K = \mathbb{Q}(i)$ with basis $1, i$, multiplication by $\alpha = a+bi$ sends $1 \mapsto a+bi$ and $i \mapsto -b+ai$, so its matrix is $\left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right)$, with trace $2a$ and determinant $a^2 + b^2$: $\mathrm{Tr}(a + bi) = (a + bi) + (a - bi)$ and $N(a + bi) = (a + bi)(a - bi)$, the sum and the product of the two conjugates, which is the general pattern of Proposition 6.5(i).

Proposition 6.5 (trace and norm)**.** *Let K be a number field of degree n with embeddings $\sigma_1, \dots, \sigma_n$, and $\alpha \in K$.*

(i) The characteristic polynomial of m_α is $\prod_i(X - \sigma_i(\alpha)) = m_\alpha(X)^{n/d}$, $d = [\mathbb{Q}(\alpha) : \mathbb{Q}]$, m_α the minimal polynomial. Hence $\mathrm{Tr}_{K/\mathbb{Q}}(\alpha) = \sum_i \sigma_i(\alpha)$ and $N_{K/\mathbb{Q}}(\alpha) = \prod_i \sigma_i(\alpha)$; Tr is $\mathbb{Q}$-linear, N is multiplicative, and $N(\alpha) = 0$ iff $\alpha = 0$. If $K = \mathbb{Q}(\alpha)$ with minimal polynomial $X^n + c_{n-1}X^{n-1} + \cdots + c_0$, then $\mathrm{Tr}(\alpha) = -c_{n-1}$ and $N(\alpha) = (-1)^n c_0$.

(ii) If $\alpha \in \mathcal{O}_K$ then $\mathrm{Tr}(\alpha), N(\alpha) \in \mathbb{Z}$, and $\alpha \in \mathcal{O}_K^\times$ if and only if $N(\alpha) = \pm 1$.

(iii) For number fields $L \supseteq K$: $\mathrm{Tr}_{L/\mathbb{Q}} = \mathrm{Tr}_{K/\mathbb{Q}} \circ \mathrm{Tr}_{L/K}$ and $N_{L/\mathbb{Q}} = N_{K/\mathbb{Q}} \circ N_{L/K}$.

Proof. (i) If $\beta_1, \dots, \beta_{n/d}$ is a basis of K over $\mathbb{Q}(\alpha)$, the elements $\beta_j\alpha^i$ $(0 \leq i < d)$ form a basis of K over $\mathbb{Q}$ in which m_α is block diagonal with n/d copies of the companion matrix of $m_\alpha(X)$; so its characteristic polynomial is $m_\alpha(X)^{n/d}$. Each of the d embeddings of $\mathbb{Q}(\alpha)$, which send α to the d distinct roots of m_α, extends to exactly n/d embeddings of K (Chapter 5), so $\prod_i(X - \sigma_i(\alpha)) = m_\alpha(X)^{n/d}$ as well. The trace of a matrix is the sum of the roots of its characteristic polynomial and the determinant their product, which gives the two formulas. The remaining statements are properties of the trace and the determinant: $m_{\alpha+\beta} = m_\alpha + m_\beta$ and $m_{c\alpha} = cm_\alpha$ for $c \in \mathbb{Q}$ give linearity of Tr; $m_{\alpha\beta} = m_\alpha m_\beta$ gives multiplicativity of N; m_α is invertible for $\alpha \neq 0$ (with inverse $m_{\alpha^{-1}}$) and $m_0 = 0$. If $K = \mathbb{Q}(\alpha)$, the characteristic polynomial is the minimal polynomial $X^n + c_{n-1}X^{n-1} + \cdots + c_0$, so the sum of its roots is $-c_{n-1}$ and their product is $(-1)^n c_0$. (ii) By Proposition 6.3(i), $m_\alpha(X) \in \mathbb{Z}[X]$, so the characteristic polynomial has integer coefficients. If $\alpha\beta = 1$ with $\beta \in \mathcal{O}_K$, then $N(\alpha)N(\beta) = 1$ in $\mathbb{Z}$. Conversely, let

$\chi(X) = X^n + \cdots + c_1 X + c_0$ be the characteristic polynomial of m_α, with $c_0 = (-1)^n N(\alpha) = \pm 1$; by Cayley-Hamilton $\chi(\alpha) = 0$, so $\alpha^{-1} = -c_0^{-1}(\alpha^{n-1} + \cdots + c_1) \in \mathbb{Z}[\alpha] \subseteq \mathcal{O}_K$. (iii) By (i) applied over K (with the same proof), $\mathrm{Tr}_{L/K}(\alpha) = \sum_\sigma \sigma(\alpha)$ over the $[L:K]$ embeddings $\sigma\colon L \to \overline{\mathbb{Q}}$ that are the identity on K. Fix an embedding $\tau\colon K \to \overline{\mathbb{Q}}$ and extend it to an automorphism $\tilde{\tau}$ of $\overline{\mathbb{Q}}$ (Chapter 5); the embeddings of L extending τ are the $\tilde{\tau} \circ \sigma$, so their sum at α is $\tau(\mathrm{Tr}_{L/K}\,\alpha)$. Summing over the $[K:\mathbb{Q}]$ choices of τ gives $\mathrm{Tr}_{L/\mathbb{Q}}(\alpha) = \mathrm{Tr}_{K/\mathbb{Q}}(\mathrm{Tr}_{L/K}\,\alpha)$; the norm is the same with products. □

Theorem 6.6 (integral bases and the discriminant)**.** *Let K be a number field of degree n.*

(i) The trace form $(x,y) \mapsto \mathrm{Tr}_{K/\mathbb{Q}}(xy)$ is a nondegenerate symmetric bilinear form on K.

(ii) $\mathcal{O}_K$ is a free $\mathbb{Z}$-module of rank n. For a $\mathbb{Z}$-basis $\beta_1, \ldots, \beta_n$ (an integral basis*) the integer $\mathrm{disc}(\beta_1, \ldots, \beta_n) = \det(\mathrm{Tr}(\beta_i\beta_j)) = \det(\sigma_k(\beta_j))^2$ is nonzero and independent of the basis; it is the* discriminant d_K *of K.*

(iii) If $\alpha_1, \ldots, \alpha_n \in \mathcal{O}_K$ are linearly independent over $\mathbb{Q}$ and $M = \mathbb{Z}\alpha_1 + \cdots + \mathbb{Z}\alpha_n$, then $\mathrm{disc}(\alpha_1, \ldots, \alpha_n) = [\mathcal{O}_K : M]^2\, d_K$. In particular, if $\mathrm{disc}(\alpha_1, \ldots, \alpha_n)$ is squarefree then $M = \mathcal{O}_K$.

(iv) If $K = \mathbb{Q}(\theta)$ with $\theta \in \mathcal{O}_K$ of minimal polynomial g, with roots $\theta_1, \ldots, \theta_n$, then

$$\mathrm{disc}(1, \theta, \ldots, \theta^{n-1}) = \prod_{i<j} (\theta_i - \theta_j)^2 = \mathrm{disc}(g) = (-1)^{n(n-1)/2} N_{K/\mathbb{Q}}(g'(\theta)).$$

Proof. (i) Symmetry and bilinearity come from the linearity of Tr (Proposition 6.5(i)). Nondegeneracy means that no $x \neq 0$ is orthogonal to all of K; and if $x \neq 0$, the element $y = x^{-1}$ gives $\mathrm{Tr}(xy) = \mathrm{Tr}(1) = n \neq 0$ (m_1 is the identity of an n-dimensional space). (ii) By Proposition 6.3 a $\mathbb{Q}$-basis of K can be multiplied by integers to lie in $\mathcal{O}_K$; let $\alpha_1, \ldots, \alpha_n$ be such a basis and $\alpha_1^\vee, \ldots, \alpha_n^\vee$ the dual basis for the trace form, which exists by (i). For $x \in \mathcal{O}_K$, $x = \sum_i \mathrm{Tr}(x\alpha_i)\alpha_i^\vee$ with $\mathrm{Tr}(x\alpha_i) \in \mathbb{Z}$ (Proposition 6.5(ii)). So $\bigoplus_i \mathbb{Z}\alpha_i \subseteq \mathcal{O}_K \subseteq \bigoplus_i \mathbb{Z}\alpha_i^\vee$, and $\mathcal{O}_K$, a subgroup of a free abelian group of rank n containing one of rank n, is free of rank n (Chapter 3). Since $\mathrm{Tr}(\beta_i\beta_j) = \sum_k \sigma_k(\beta_i)\sigma_k(\beta_j)$, the Gram matrix is $S^{\mathsf{T}}S$ with $S = (\sigma_k(\beta_j))_{k,j}$, which gives the second expression; it is nonzero by (i). If $\beta' = C\beta$ is another basis, $C \in \mathrm{GL}_n(\mathbb{Z})$, the Gram matrix becomes $C(\cdot)C^{\mathsf{T}}$ and the determinant is multiplied by $\det(C)^2 = 1$. (iii) Write $\alpha = C\beta$ with $C \in \mathrm{M}_n(\mathbb{Z})$; then $\mathrm{disc}(\alpha) = \det(C)^2 d_K$, and $|\det C| = [\mathcal{O}_K : M]$ by the elementary divisor theorem (Chapter 3). If $\mathrm{disc}(\alpha)$ is squarefree, the square $[\mathcal{O}_K : M]^2$ dividing it is 1. (iv) With $\sigma_k(\theta) = \theta_k$, the matrix $(\sigma_k(\theta^{j-1}))$ is the Vandermonde matrix of the θ_k, of determinant $\prod_{i<j}(\theta_j - \theta_i)$; its square is $\prod_{i<j}(\theta_i - \theta_j)^2$, which is $\mathrm{disc}(g)$ by definition. Writing $g(X) = \prod_k (X - \theta_k)$, the product rule gives $g'(\theta_i) = \prod_{k \neq i}(\theta_i - \theta_k)$. In the product $\prod_i \prod_{k \neq i}(\theta_i - \theta_k)$ each unordered pair $\{i,j\}$, $i < j$, contributes the two factors $(\theta_i - \theta_j)(\theta_j - \theta_i) = -(\theta_i - \theta_j)^2$; there are $n(n-1)/2$ pairs, so the product is $(-1)^{n(n-1)/2} \prod_{i<j}(\theta_i - \theta_j)^2$. Finally $\prod_i g'(\theta_i) = \prod_i \sigma_i(g'(\theta)) = N(g'(\theta))$ by Proposition 6.5(i). For example, for $g = X^2 - d$ the formula gives $(-1)^1 N(2\sqrt{d}) = -(2\sqrt{d})(-2\sqrt{d}) = 4d$, the discriminant of $1, \sqrt{d}$ found again in Proposition 6.7. □

Proposition 6.7 (quadratic fields)**.** *Let $d \in \mathbb{Z}$ be squarefree, $d \neq 0, 1$, and $K = \mathbb{Q}(\sqrt{d})$. If $d \equiv 2, 3 \pmod 4$ then $\mathcal{O}_K = \mathbb{Z}[\sqrt{d}]$ and $d_K = 4d$; if $d \equiv 1 \pmod 4$ then $\mathcal{O}_K = \mathbb{Z}[\frac{1+\sqrt{d}}{2}]$ and $d_K = d$. A* fundamental discriminant *is an integer $D \neq 1$ that is either squarefree with $D \equiv 1 \pmod 4$, or $D = 4m$ with m squarefree and $m \equiv 2, 3 \pmod 4$; the map $K \mapsto d_K$ is a bijection*

from quadratic fields to fundamental discriminants, with inverse $D \mapsto \mathbb{Q}(\sqrt{D})$. *The norm forms are* $N(a+b\sqrt{d}) = a^2 - db^2$ *and, for* $d \equiv 1 \pmod 4$ *and* $\theta_d = \frac{1+\sqrt{d}}{2}$, $N(a+b\theta_d) = a^2 + ab + \frac{1-d}{4}b^2$.

Proof. Let $\alpha = a + b\sqrt{d}$ with $a, b \in \mathbb{Q}$, $b \neq 0$. Its minimal polynomial is $X^2 - 2aX + (a^2 - db^2)$, so $\alpha \in \mathcal{O}_K$ iff $2a \in \mathbb{Z}$ and $a^2 - db^2 \in \mathbb{Z}$. If $a \in \mathbb{Z}$ then $db^2 \in \mathbb{Z}$, and $b \in \mathbb{Z}$ because d is squarefree (if $b = u/v$ in lowest terms, $v^2 \mid du^2$, so $v^2 \mid d$). If $a = A/2$ with A odd, then $4(a^2 - db^2) = A^2 - d(2b)^2 \in 4\mathbb{Z}$, so $d(2b)^2 \in \mathbb{Z}$, $B := 2b \in \mathbb{Z}$ as before, and $A^2 \equiv dB^2 \pmod 4$ with A odd forces B odd and $d \equiv 1 \pmod 4$. This gives $\mathcal{O}_K$. For the basis $1, \sqrt{d}$ the Gram matrix of the trace form is $\operatorname{diag}(2, 2d)$, of determinant $4d$; for $1, \theta_d$ it is $\left(\begin{smallmatrix} 2 & 1 \\ 1 & (1+d)/2 \end{smallmatrix}\right)$, of determinant d. The fundamental discriminants are exactly these values: d for $d \equiv 1 \pmod 4$ and $4d$ for $d \equiv 2, 3 \pmod 4$, and $\mathbb{Q}(\sqrt{d_K}) = K$. The norm forms follow from $N(x) = x\bar{x}$. □

Example 6.8. $\mathbb{Q}(i)$: $\mathcal{O} = \mathbb{Z}[i]$, $D = -4$, $N(a+bi) = a^2 + b^2$. $\mathbb{Q}(\sqrt{-3})$: $\mathcal{O} = \mathbb{Z}[\zeta_3]$ since $\zeta_3 = \frac{-1+\sqrt{-3}}{2} = \theta_{-3} - 1$, $D = -3$, and $N(a + b\zeta_3) = a^2 - ab + b^2$; the subring $\mathbb{Z}[\sqrt{-3}]$ has index 2 (its discriminant is $-12 = 2^2 \cdot (-3)$, Theorem 6.6(iii)) and is not integrally closed, which is why unique factorisation fails in it (Chapter 2, where $4 = 2 \cdot 2 = (1 + \sqrt{-3})(1 - \sqrt{-3})$). $\mathbb{Q}(\sqrt{5})$: $\mathcal{O} = \mathbb{Z}[\frac{1+\sqrt{5}}{2}]$, $D = 5$. $\mathbb{Q}(\sqrt{-7})$, $\mathbb{Q}(\sqrt{-11})$: $D = -7, -11$. $\mathbb{Q}(\sqrt{-5})$, $\mathbb{Q}(\sqrt{2})$: $D = -20, 8$.

Theorem 6.9 (units)**.** *(i) (Dirichlet's unit theorem.)* $\mathcal{O}_K^\times \simeq \mu(K) \times \mathbb{Z}^{r_1+r_2-1}$, *where* $\mu(K)$, *the group of roots of unity in* K, *is finite and cyclic. (ii) If* K *is imaginary quadratic,* $\mathcal{O}_K^\times = \mu(K)$, *which is* $\{\pm 1\}$ *except for* $\mu(\mathbb{Q}(i)) = \{\pm 1, \pm i\} = \mu_4$ *and* $\mu(\mathbb{Q}(\sqrt{-3})) = \{\pm 1, \pm\zeta_3, \pm\zeta_3^2\} = \mu_6$. *(iii)* $\mathbb{Z}[\sqrt{2}]^\times = \{\pm(1+\sqrt{2})^k : k \in \mathbb{Z}\}$.

Proof. (i) We do not prove this; see [142, Chapter I, Section 7] or [123, Chapter 5]. (ii) A unit has norm ± 1 (Proposition 6.5(ii)), and norms are ≥ 0 in an imaginary quadratic field, so units are the elements of norm 1. For $d \equiv 2, 3 \pmod 4$, $d < 0$: $a^2 + |d|b^2 = 1$ has the solutions $(\pm 1, 0)$, and also $(0, \pm 1)$ when $d = -1$. For $d \equiv 1 \pmod 4$, $d < 0$: with $\alpha = (A + B\sqrt{d})/2$, $A \equiv B \pmod 2$, the equation is $A^2 + |d|B^2 = 4$; for $|d| \geq 7$ only $B = 0$, $A = \pm 2$; for $d = -3$ also $A = \pm 1$, $B = \pm 1$, which are the six elements $\pm 1, \pm\zeta_3, \pm\zeta_3^2$. (iii) Let $u_0 = 1 + \sqrt{2}$, a unit of norm $1 - 2 = -1$. If $u = a + b\sqrt{2} > 1$ is a unit ($a, b \in \mathbb{Z}$), its conjugate $\bar{u} = a - b\sqrt{2}$ satisfies $u\bar{u} = N(u) = \pm 1$, so $\bar{u} = \pm u^{-1}$ has $|\bar{u}| < 1$; hence $a = (u + \bar{u})/2 > (1 - 1)/2 = 0$ and $b\sqrt{2} = (u - \bar{u})/2 > 0$. So a and b are positive integers, $a, b \geq 1$, and $u \geq 1 + \sqrt{2} = u_0$: u_0 is the smallest unit greater than 1. Given any unit $u > 0$, choose k with $u_0^k \leq u < u_0^{k+1}$; then $u\,u_0^{-k}$ is a unit in $[1, u_0)$, so it is 1. Units $u < 0$ are -1 times positive ones. □

The units of $\mathbb{Z}[\zeta_3]$ enter the paper through the relation $(1 - \zeta_3)^2 = -3$ up to a unit: $3 = -\zeta_3^2(1 - \zeta_3)^2$ and $\zeta_3^2 \in \mu_6$ (Proposition 6.39). It makes $1 - \zeta_3$ a uniformiser of the discrete valuation ring $\mathbb{Z}_3[\zeta_3]$ of the paragraph after Lemma lem:IV, and gives $T/(1 - \zeta_3)T \simeq \mathbb{F}_3$ in the proof of Lemma lem:tamadd.

So far $\mathcal{O}_K$ is known as an abelian group ($\mathbb{Z}^n$) and through its units. What it lacks in general is unique factorisation of elements, and the next section replaces it by unique factorisation of ideals; that is the structure behind the primes λ, the valuations and the residue fields used everywhere later.

6.2 Dedekind domains, ideals, norms and class groups

Unique factorisation of elements fails in rings of integers, but unique factorisation of ideals holds, and it is what gives meaning to "a prime $\lambda \mid \ell$", to the valuation v_λ and to the residue field

$\mathcal{O}/\lambda$ in Lemmas lem:crit and lem:old of the paper. This section proves it (Theorem 6.13), with the norm of an ideal, the Chinese remainder theorem and the localisations, which are discrete valuation rings in the sense of Chapter 3. The class group is described but not used by the paper: the rings $\mathbb{Z}[i]$ and $\mathbb{Z}[\zeta_3]$ that the paper needs are principal ideal domains.

Definition 6.10. A *Dedekind domain* is a Noetherian integral domain R, not a field, which is integrally closed in its fraction field and in which every nonzero prime ideal is maximal.

The three conditions are exactly what the proof of unique factorisation of ideals uses, and each can fail on its own. Noetherian guarantees that the inductions over ideals terminate. Integral closedness fails for $\mathbb{Z}[\sqrt{-3}]$, which misses the integral element ζ_3, and Exercise 6.73 shows that ideals cannot be cancelled there. "Nonzero primes are maximal" (dimension one) fails for $\mathbb{Z}[X]$, which is Noetherian and integrally closed (a UFD) but has the chain of primes $0 \subsetneq (X) \subsetneq (2, X)$; and in $\mathbb{Z}[X]$ the ideal $(4, X)$ is not a product of primes at all: a prime factor would contain $(4, X)$, hence 2 and X, hence be the maximal ideal $(2, X)$, but $(2, X) \neq (4, X)$ (as $2 \notin (4, X)$) and $(2, X)^k \subseteq (4, 2X, X^2) \not\ni X$ for $k \geq 2$. The rings of the paper, $\mathcal{O}_K$, $\mathbb{Z}[i]$, $\mathbb{Z}[\zeta_3]$, $\mathbb{Z}_3[\zeta_3]$, satisfy all three.

Theorem 6.11. *(i) For every number field K, $\mathcal{O}_K$ is a Dedekind domain; for a nonzero prime $\mathfrak{p}$ of $\mathcal{O}_K$, $\mathfrak{p} \cap \mathbb{Z} = p\mathbb{Z}$ for a prime p, and $\mathcal{O}_K/\mathfrak{p}$ is a finite field of characteristic p. (ii) A principal ideal domain that is not a field is a Dedekind domain. (iii) A Noetherian domain R that is not a field is a Dedekind domain if and only if the localisation $R_\mathfrak{p}$ is a discrete valuation ring for every nonzero prime $\mathfrak{p}$.*

Proof. (i) $\mathcal{O}_K$ is a free $\mathbb{Z}$-module of finite rank (Theorem 6.6), so every ideal, a subgroup, is finitely generated: $\mathcal{O}_K$ is Noetherian. It is integrally closed (Proposition 6.3) and not a field ($\frac{1}{2} \notin \mathcal{O}_K$). Let $\mathfrak{p} \neq 0$ be prime and $0 \neq \alpha \in \mathfrak{p}$, with minimal polynomial $X^d + \cdots + c_1X + c_0$; then $c_0 \neq 0$ by irreducibility, and $c_0 = -\alpha(\alpha^{d-1} + \cdots + c_1) \in \mathfrak{p} \cap \mathbb{Z}$. So $\mathfrak{p} \cap \mathbb{Z}$ is a nonzero prime ideal of $\mathbb{Z}$, equal to $p\mathbb{Z}$. Then $\mathcal{O}_K/\mathfrak{p}$ is a quotient of $\mathcal{O}_K/p\mathcal{O}_K \simeq (\mathbb{Z}/p)^n$, a finite integral domain, hence a field: $\mathfrak{p}$ is maximal. (ii) A PID is Noetherian, is a UFD and hence integrally closed (Chapter 2), and a nonzero prime (ϖ) is maximal: if $(\varpi) \subseteq (a)$ then $\varpi = ab$, and $\varpi \mid a$ or $\varpi \mid b$, so $(a) = (\varpi)$ or $(a) = R$. (iii) "Only if" is Proposition 6.15(iv) below, whose proof uses only Theorem 6.13. "If": a discrete valuation ring is integrally closed (Chapter 3). If $x \in K$ lies in $R_\mathfrak{m}$ for every maximal ideal $\mathfrak{m}$, the ideal $\{r \in R : rx \in R\}$ is contained in no maximal ideal (for each $\mathfrak{m}$ write $x = a/s$ with $a \in R$, $s \notin \mathfrak{m}$; then s lies in the ideal but not in $\mathfrak{m}$), so it is R, it contains 1, and $x \in R$. Hence $R = \bigcap_\mathfrak{m} R_\mathfrak{m}$. Now if $x \in K$ is a root of a monic polynomial with coefficients in R, it is integral over each $R_\mathfrak{m} \supseteq R$, so it lies in each $R_\mathfrak{m}$, hence in R: R is integrally closed. If $0 \neq \mathfrak{q} \subsetneq \mathfrak{m}$ were primes, $\mathfrak{q}R_\mathfrak{m} \subsetneq \mathfrak{m}R_\mathfrak{m}$ would be two distinct nonzero primes of the discrete valuation ring $R_\mathfrak{m}$, which has only one. □

Lemma 6.12. *Let R be a Dedekind domain with fraction field K, and for a nonzero prime $\mathfrak{p}$ put $\mathfrak{p}^{-1} = \{x \in K : x\mathfrak{p} \subseteq R\}$. (i) Every nonzero ideal of R contains a product of nonzero prime ideals. (ii) For every nonzero ideal $\mathfrak{a}$, $\mathfrak{a}\mathfrak{p}^{-1} \neq \mathfrak{a}$; in particular $\mathfrak{p}^{-1} \neq R$. (iii) $\mathfrak{p}\mathfrak{p}^{-1} = R$.*

Proof. (i) If not, the set of nonzero ideals not containing such a product is nonempty and has a maximal element $\mathfrak{a}$ (R is Noetherian). It is not prime (a nonzero prime contains the product of one prime, itself), and not R (which contains every product), so there are $b, c \notin \mathfrak{a}$ with $bc \in \mathfrak{a}$; the ideals $\mathfrak{a} + (b)$ and $\mathfrak{a} + (c)$ are strictly larger, so by maximality they contain products of primes, and their product $(\mathfrak{a} + (b))(\mathfrak{a} + (c)) \subseteq \mathfrak{a} + (bc) = \mathfrak{a}$ contains the product of these

two products: a contradiction. (ii) First $\mathfrak{p}^{-1} \neq R$: take $0 \neq a \in \mathfrak{p}$ and, by (i), primes with $\mathfrak{p}_1 \cdots \mathfrak{p}_r \subseteq (a) \subseteq \mathfrak{p}$, r minimal. Some $\mathfrak{p}_i \subseteq \mathfrak{p}$: otherwise choose $x_i \in \mathfrak{p}_i \setminus \mathfrak{p}$, and $x_1 \cdots x_r \in \mathfrak{p}$ contradicts the primality of $\mathfrak{p}$. Say $\mathfrak{p}_1 \subseteq \mathfrak{p}$; as $\mathfrak{p}_1$ is a nonzero prime, it is maximal, so $\mathfrak{p}_1 = \mathfrak{p}$. By minimality of r, $\mathfrak{p}_2 \cdots \mathfrak{p}_r \not\subseteq (a)$ (for $r = 1$ read $\mathfrak{p}_2 \cdots \mathfrak{p}_r = R$), so there is $b \in \mathfrak{p}_2 \cdots \mathfrak{p}_r$ with $b \notin (a)$. Then $b\mathfrak{p} \subseteq \mathfrak{p}_1\mathfrak{p}_2 \cdots \mathfrak{p}_r \subseteq (a)$, so $(b/a)\mathfrak{p} \subseteq R$, that is $b/a \in \mathfrak{p}^{-1}$, while $b/a \notin R$ because $b \notin aR$. Now let $\mathfrak{a} = (\alpha_1, \ldots, \alpha_m) \neq 0$ with $\mathfrak{a}\mathfrak{p}^{-1} = \mathfrak{a}$. For $x \in \mathfrak{p}^{-1}$, $x\alpha_i \in \mathfrak{a}$, so $x\alpha_i = \sum_j a_{ij}\alpha_j$ with $a_{ij} \in R$, and the adjugate argument of Proposition 6.3 gives $\det(xI - (a_{ij}))\alpha_j = 0$ for all j, hence $\det(xI - (a_{ij})) = 0$ (as R is a domain and some $\alpha_j \neq 0$): x is a root of a monic polynomial over R, and $x \in R$ because R is integrally closed. So $\mathfrak{p}^{-1} \subseteq R$, contradicting the first step. (iii) $\mathfrak{p}\mathfrak{p}^{-1}$ is an ideal of R (by the definition of $\mathfrak{p}^{-1}$), it contains $\mathfrak{p}$ (as $1 \in \mathfrak{p}^{-1}$), and $\mathfrak{p}\mathfrak{p}^{-1} \neq \mathfrak{p}$ by (ii) with $\mathfrak{a} = \mathfrak{p}$. Since $\mathfrak{p}$ is maximal, $\mathfrak{p}\mathfrak{p}^{-1} = R$. □

Theorem 6.13 (unique factorisation of ideals)**.** *Let R be a Dedekind domain with fraction field K.*

(i) Every nonzero ideal $\mathfrak{a} \neq R$ is a product $\mathfrak{a} = \mathfrak{p}_1^{a_1} \cdots \mathfrak{p}_r^{a_r}$ of distinct nonzero primes, $a_i \geq 1$, uniquely up to order. We write $v_\mathfrak{p}(\mathfrak{a})$ for the exponent of $\mathfrak{p}$ (0 if $\mathfrak{p}$ does not occur).

(ii) A fractional ideal *is a nonzero finitely generated R-submodule of K, equivalently a set $x\mathfrak{b}$ with $x \in K^\times$ and $\mathfrak{b}$ a nonzero ideal. The fractional ideals form an abelian group J_R under multiplication, free on the nonzero primes; the inverse of $\mathfrak{a}$ is $\mathfrak{a}^{-1} = \{x \in K : x\mathfrak{a} \subseteq R\}$.*

(iii) For nonzero ideals, $\mathfrak{a} \mid \mathfrak{b}$ (that is, $\mathfrak{b} = \mathfrak{a}\mathfrak{c}$ for an ideal $\mathfrak{c}$) if and only if $\mathfrak{a} \supseteq \mathfrak{b}$; $\mathfrak{a} + \mathfrak{b}$ and $\mathfrak{a} \cap \mathfrak{b}$ have exponents min *and* max *of those of $\mathfrak{a}$, $\mathfrak{b}$.*

(iv) For $\alpha \in K^\times$ put $v_\mathfrak{p}(\alpha) = v_\mathfrak{p}(\alpha R)$. Then $v_\mathfrak{p}(\alpha\beta) = v_\mathfrak{p}(\alpha) + v_\mathfrak{p}(\beta)$ and $v_\mathfrak{p}(\alpha + \beta) \geq \min(v_\mathfrak{p}(\alpha), v_\mathfrak{p}(\beta))$: $v_\mathfrak{p}$ is a discrete valuation of K.

Proof. (i) Existence: otherwise let $\mathfrak{a}$ be maximal among the nonzero proper ideals that are not products of primes, and $\mathfrak{p} \supseteq \mathfrak{a}$ a maximal ideal. Then $\mathfrak{a} \subseteq \mathfrak{a}\mathfrak{p}^{-1} \subseteq \mathfrak{p}\mathfrak{p}^{-1} = R$, with $\mathfrak{a} \neq \mathfrak{a}\mathfrak{p}^{-1}$ (Lemma 6.12). If $\mathfrak{a}\mathfrak{p}^{-1} = R$ then $\mathfrak{a} = \mathfrak{a}\mathfrak{p}^{-1}\mathfrak{p} = \mathfrak{p}$, a prime; otherwise $\mathfrak{a}\mathfrak{p}^{-1} = \mathfrak{p}_1 \cdots \mathfrak{p}_s$ by maximality, and $\mathfrak{a} = \mathfrak{p}_1 \cdots \mathfrak{p}_s\mathfrak{p}$. Either way a contradiction. Uniqueness: if $\mathfrak{p}_1 \cdots \mathfrak{p}_r = \mathfrak{q}_1 \cdots \mathfrak{q}_s$, then $\mathfrak{p}_1$ contains the right side, hence some $\mathfrak{q}_j$, and $\mathfrak{p}_1 = \mathfrak{q}_j$ by maximality; multiply by $\mathfrak{p}_1^{-1}$ (Lemma 6.12(iii)) and induct. (ii) A fractional ideal $\mathfrak{a}$ with generators $x_i = a_i/s$ satisfies $s\mathfrak{a} \subseteq R$, so $\mathfrak{a} = s^{-1}\mathfrak{b}$; writing sR and $\mathfrak{b}$ as products of primes, $\mathfrak{a} = \prod \mathfrak{p}^{a_\mathfrak{p}}$ with $a_\mathfrak{p} \in \mathbb{Z}$, almost all zero, and the exponents are unique by (i) after multiplying by a common denominator. Put $\mathfrak{a}' = \prod \mathfrak{p}^{-a_\mathfrak{p}}$; then $\mathfrak{a}\mathfrak{a}' = R$, so $\mathfrak{a}' \subseteq \mathfrak{c} := \{x : x\mathfrak{a} \subseteq R\}$, and $\mathfrak{c} = \mathfrak{c}\mathfrak{a}\mathfrak{a}' \subseteq \mathfrak{a}'$. (iii) If $\mathfrak{a} \supseteq \mathfrak{b}$, then $\mathfrak{c} = \mathfrak{a}^{-1}\mathfrak{b} \subseteq \mathfrak{a}^{-1}\mathfrak{a} = R$ is an ideal with $\mathfrak{b} = \mathfrak{a}\mathfrak{c}$; the converse is clear. So $\mathfrak{a} \supseteq \mathfrak{b}$ iff $v_\mathfrak{p}(\mathfrak{a}) \leq v_\mathfrak{p}(\mathfrak{b})$ for all $\mathfrak{p}$; $\mathfrak{a} + \mathfrak{b}$ is the smallest ideal containing both, $\mathfrak{a} \cap \mathfrak{b}$ the largest contained in both, whence the exponents. (iv) The first identity is (i); and $(\alpha + \beta) \subseteq (\alpha) + (\beta)$, whose exponent at $\mathfrak{p}$ is the minimum, by (iii) extended to fractional ideals by scaling. □

Fractional ideals are introduced so that ideals can be inverted, as rational numbers invert integers. For $R = \mathbb{Z}$ the fractional ideals are the groups $r\mathbb{Z}$, $r \in \mathbb{Q}_{>0}$, and $J_\mathbb{Z} \simeq \mathbb{Q}_{>0}^\times$, free on the primes: $\frac{12}{5}\mathbb{Z} = (2)^2(3)(5)^{-1}$. In $\mathbb{Z}[\sqrt{-5}]$, with the primes of Example 6.18, $\mathfrak{p}_2^{-1} = \frac{1}{2}\mathfrak{p}_2$ (because $\mathfrak{p}_2 \cdot \frac{1}{2}\mathfrak{p}_2 = \frac{1}{2}(2) = R$), a fractional ideal that is not of the form xR. The valuation $v_\mathfrak{p}$ of (iv) is the exponent of $\mathfrak{p}$ in αR; for $\mathcal{O}_K = \mathbb{Z}[i]$ and $\mathfrak{p} = (1 + i)$, for instance, $v_\mathfrak{p}(2) = 2$ since $2 = -i(1 + i)^2$, and $v_\mathfrak{p}(3) = 0$.

Proposition 6.14 (the norm of an ideal)**.** *Let K be a number field. For a nonzero ideal $\mathfrak{a} \subseteq \mathcal{O}_K$ the* norm *$N\mathfrak{a} = \#(\mathcal{O}_K/\mathfrak{a})$ is finite, and:*

(i) $N(\mathfrak{ab}) = N\mathfrak{a}\,N\mathfrak{b}$; for a prime $\mathfrak{p}$ and $k \geq 0$, $\mathfrak{p}^k/\mathfrak{p}^{k+1} \simeq \mathcal{O}_K/\mathfrak{p}$ as $\mathcal{O}_K$-modules;

(ii) $N(\alpha\mathcal{O}_K) = |N_{K/\mathbb{Q}}(\alpha)|$ for $\alpha \neq 0$;

(iii) if $\mathfrak{p} \cap \mathbb{Z} = p\mathbb{Z}$ then $\mathcal{O}_K/\mathfrak{p} \simeq \mathbb{F}_{p^f}$, where $f = f(\mathfrak{p} \mid p) = [\mathcal{O}_K/\mathfrak{p} : \mathbb{F}_p]$, and $N\mathfrak{p} = p^f$;

(iv) an ideal of prime norm is prime; $N\mathfrak{a} \in \mathfrak{a}$; and if $\gcd(N\mathfrak{a}, m) = 1$ then $\mathfrak{a} + m\mathcal{O}_K = \mathcal{O}_K$;

(v) the discriminant of a $\mathbb{Z}$-basis of $\mathfrak{a}$ is $(N\mathfrak{a})^2 d_K$.

Proof. $\mathfrak{a}$ contains a nonzero integer m (the constant term c_0 of the proof of Theorem 6.11), and $\mathcal{O}_K/m\mathcal{O}_K \simeq (\mathbb{Z}/m)^n$ is finite. (i) The module $M = \mathfrak{a}/\mathfrak{ap}$ is a vector space over $\mathcal{O}_K/\mathfrak{p}$; it is nonzero (Theorem 6.13) and has no subspace other than 0 and M, because an ideal $\mathfrak{b}$ with $\mathfrak{ap} \subseteq \mathfrak{b} \subseteq \mathfrak{a}$ satisfies $\mathfrak{a} \mid \mathfrak{b} \mid \mathfrak{ap}$, so $\mathfrak{b} \in \{\mathfrak{a}, \mathfrak{ap}\}$. Hence M is one-dimensional, $M \simeq \mathcal{O}_K/\mathfrak{p}$, and $N(\mathfrak{ap}) = N\mathfrak{a} \cdot \#(\mathfrak{a}/\mathfrak{ap}) = N\mathfrak{a}\,N\mathfrak{p}$; induction on the number of prime factors of $\mathfrak{b}$ gives the claim. (ii) $[\mathcal{O}_K : \alpha\mathcal{O}_K]$ is $|\det|$ of the matrix of m_α on a $\mathbb{Z}$-basis (Chapter 3), which is $|N(\alpha)|$. (iii) $\mathcal{O}_K/\mathfrak{p}$ is a finite field (Theorem 6.11) containing $\mathbb{Z}/p$. (iv) If $N\mathfrak{a} = p$ is prime, $\mathfrak{a} \neq \mathcal{O}_K$, and a factorisation $\mathfrak{a} = \mathfrak{bc}$ into proper ideals would give $N\mathfrak{a} = N\mathfrak{b}\,N\mathfrak{c}$ composite. The additive group $\mathcal{O}_K/\mathfrak{a}$ has order $N\mathfrak{a}$, so $N\mathfrak{a} \cdot 1 \in \mathfrak{a}$; if $uN\mathfrak{a} + vm = 1$, then $1 \in \mathfrak{a} + m\mathcal{O}_K$. (v) is Theorem 6.6(iii), with $[\mathcal{O}_K : \mathfrak{a}] = N\mathfrak{a}$. □

Proposition 6.15 (Chinese remainder theorem, generators, localisation)**.** *In (ii) to (iv), R is a Dedekind domain.*

(i) In a commutative ring R, let $\mathfrak{a}_1, \ldots, \mathfrak{a}_r$ be pairwise coprime ideals, that is, $\mathfrak{a}_i + \mathfrak{a}_j = R$ for $i \neq j$. Then

$$\mathfrak{a}_1 \cdots \mathfrak{a}_r = \bigcap_i \mathfrak{a}_i \quad \text{and} \quad R/\mathfrak{a}_1 \cdots \mathfrak{a}_r \simeq \prod_i R/\mathfrak{a}_i.$$

In a Dedekind domain, powers of distinct primes are coprime, so $R/\mathfrak{a} \simeq \prod_i R/\mathfrak{p}_i^{a_i}$ for $\mathfrak{a} = \prod \mathfrak{p}_i^{a_i}$, and $R/\mathfrak{p}^a$ has length a, with composition factors $\mathfrak{p}^k/\mathfrak{p}^{k+1} \simeq R/\mathfrak{p}$.

(ii) In a Dedekind domain every nonzero ideal $\mathfrak{a}$ is generated by two elements, the first an arbitrary nonzero $\alpha \in \mathfrak{a}$.

(iii) A Dedekind domain with finitely many primes is a principal ideal domain; a Dedekind domain is a UFD if and only if it is a PID.

(iv) For a nonzero prime $\mathfrak{p}$ of a Dedekind domain R, $R_\mathfrak{p}$ is a discrete valuation ring with maximal ideal $\mathfrak{p}R_\mathfrak{p}$, residue field $R/\mathfrak{p}$, and valuation $v_\mathfrak{p}$.

Proof. (i) For two ideals, $1 = a + b$ with $a \in \mathfrak{a}_1$, $b \in \mathfrak{a}_2$; then $\mathfrak{a}_1 \cap \mathfrak{a}_2 = (\mathfrak{a}_1 \cap \mathfrak{a}_2)(a+b) \subseteq \mathfrak{a}_1\mathfrak{a}_2$, and $x \mapsto (x \bmod \mathfrak{a}_1, x \bmod \mathfrak{a}_2)$ is surjective since (x, y) is the image of $xb + ya$. Induct, using that $\mathfrak{a}_1$ is coprime to $\mathfrak{a}_2 \cdots \mathfrak{a}_r$ (expand $1 = \prod_{j \geq 2}(a_j + b_j)$). In a Dedekind domain, a maximal ideal containing $\mathfrak{p}^a + \mathfrak{q}^b$ contains $\mathfrak{p}$ and $\mathfrak{q}$, so equals both; hence distinct primes give coprime powers. The filtration $R \supseteq \mathfrak{p} \supseteq \cdots \supseteq \mathfrak{p}^a$ has the quotients of Proposition 6.14(i), whose proof holds in any Dedekind domain. (ii) Let $\mathfrak{p}_1, \ldots, \mathfrak{p}_r$ be the primes dividing αR, $e_i = v_{\mathfrak{p}_i}(\mathfrak{a})$, and choose $x_i \in \mathfrak{p}_i^{e_i} \setminus \mathfrak{p}_i^{e_i+1}$. By (i) there is $\beta \in R$ with $\beta \equiv x_i \pmod{\mathfrak{p}_i^{e_i+1}}$ for all i; then $v_{\mathfrak{p}_i}(\beta) = e_i$. Every prime dividing $\mathfrak{a}$ divides αR, so $\beta \in \mathfrak{a}$ (Theorem 6.13(iii)), and $(\alpha, \beta) = \alpha R + \beta R$ has exponent

$\min(v_{\mathfrak{p}_i}(\alpha), e_i) = e_i$ at $\mathfrak{p}_i$ and 0 elsewhere: it is $\mathfrak{a}$. (iii) If the primes are $\mathfrak{p}_1, \dots, \mathfrak{p}_r$, choose by (i) $\pi_i \equiv x_i \pmod{\mathfrak{p}_i^2}$ with $x_i \in \mathfrak{p}_i \setminus \mathfrak{p}_i^2$ and $\pi_i \equiv 1 \pmod{\mathfrak{p}_j}$ for $j \neq i$ (the ideals $\mathfrak{p}_i^2$ and $\mathfrak{p}_j$, $j \neq i$, are pairwise coprime). Then $\pi_i \in \mathfrak{p}_i$, $\pi_i \notin \mathfrak{p}_i^2$ (since $\pi_i - x_i \in \mathfrak{p}_i^2$ and $x_i \notin \mathfrak{p}_i^2$) and $\pi_i \notin \mathfrak{p}_j$; so $v_{\mathfrak{p}_i}(\pi_i) = 1$ and $v_{\mathfrak{p}_j}(\pi_i) = 0$, and as there are no other primes, $\pi_i R = \mathfrak{p}_i$ by Theorem 6.13(i). Every ideal, a product of primes, is then principal. A PID is a UFD (Chapter 2). Conversely, in a UFD a nonzero prime $\mathfrak{p}$ contains a nonzero element, hence one of its irreducible factors ϖ, which is a prime element; $(\varpi) \subseteq \mathfrak{p}$ is a nonzero prime ideal, hence maximal, so $\mathfrak{p} = (\varpi)$, and all ideals are principal. (iv) A nonzero ideal A of $R_{\mathfrak{p}}$ is $(A \cap R)R_{\mathfrak{p}}$, and for a prime $\mathfrak{q} \neq \mathfrak{p}$, $\mathfrak{q}R_{\mathfrak{p}} = R_{\mathfrak{p}}$ ($\mathfrak{q} \not\subseteq \mathfrak{p}$). So $A = \mathfrak{p}^a R_{\mathfrak{p}}$ with $a = v_{\mathfrak{p}}(A \cap R)$. If $\varpi \in \mathfrak{p} \setminus \mathfrak{p}^2$ then $\varpi R = \mathfrak{p}\mathfrak{b}$ with $\mathfrak{b}$ prime to $\mathfrak{p}$, so $\varpi R_{\mathfrak{p}} = \mathfrak{p}R_{\mathfrak{p}}$, and every nonzero ideal is $\varpi^a R_{\mathfrak{p}}$: $R_{\mathfrak{p}}$ is a local principal ideal domain, not a field, that is, a discrete valuation ring (Chapter 3). Its valuation of α is the exponent a with $\alpha R_{\mathfrak{p}} = \varpi^a R_{\mathfrak{p}}$, which is $v_{\mathfrak{p}}(\alpha)$. The map $R/\mathfrak{p} \to R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}}$ is injective ($\mathfrak{p}R_{\mathfrak{p}} \cap R = \mathfrak{p}$) and surjective (an $s \notin \mathfrak{p}$ is invertible modulo the maximal ideal $\mathfrak{p}$). □

Theorem 6.16 (the class group)**.** *Let K be a number field, J_K its group of fractional ideals and P_K the subgroup of principal fractional ideals $\alpha\mathcal{O}_K$. The* class group *is $\mathrm{Cl}(K) = J_K/P_K$ and the* class number *is $h_K = \#\,\mathrm{Cl}(K)$; $h_K = 1$ iff $\mathcal{O}_K$ is a PID iff it is a UFD (Proposition 6.15(iii)). (Minkowski.) $\mathrm{Cl}(K)$ is finite: every class contains an integral ideal of norm at most $M_K = (4/\pi)^{r_2}\,(n!/n^n)\,|d_K|^{1/2}$. Moreover $|d_K| > 1$ for $K \neq \mathbb{Q}$.*

Reference. The definitions and the equivalences are proved above. We do not prove Minkowski's theorem; see [142, Chapter I, Sections 5 and 6] or [123, Chapter 5]. The idea: the embeddings $(\sigma_1, \dots, \sigma_{r_1+r_2})$ map an ideal $\mathfrak{a}$ to a lattice in $\mathbb{R}^{r_1} \times \mathbb{C}^{r_2} \simeq \mathbb{R}^n$ of covolume $2^{-r_2}|d_K|^{1/2} N\mathfrak{a}$ (the Gram determinant of Theorem 6.6, up to the factor 2^{-r_2} from the coordinates of $\mathbb{C}$), and Minkowski's convex body theorem gives $\alpha \in \mathfrak{a}$ with $|N(\alpha)| \leq M_K N\mathfrak{a}$. The inequality $|d_K| > 1$ follows: an integral ideal has norm at least 1, so $M_K \geq 1$, that is $|d_K|^{1/2} \geq (\pi/4)^{r_2} n^n/n! \geq (\pi/4)^{n/2} n^n/n!$, and the last expression is $\pi/2 > 1$ for $n = 2$ and increases with n (the ratio of consecutive terms is $(\pi/4)^{1/2}(1 + \frac{1}{n})^n \geq 2(\pi/4)^{1/2} > 1$). □

Example 6.17 (class numbers of small quadratic fields)**.** For a quadratic field $n!/n^n = \frac{1}{2}$, so $M_K = \frac{2}{\pi}|D|^{1/2}$ if $D < 0$ and $M_K = \frac{1}{2}D^{1/2}$ if $D > 0$. Hence (all values computed with PARI's `quadclassunit`, which also confirms the class numbers):

K	$\mathbb{Q}(\sqrt{-3})$	$\mathbb{Q}(i)$	$\mathbb{Q}(\sqrt{-7})$	$\mathbb{Q}(\sqrt{5})$	$\mathbb{Q}(\sqrt{2})$	$\mathbb{Q}(\sqrt{-11})$	$\mathbb{Q}(\sqrt{-5})$
D	-3	-4	-7	5	8	-11	-20
M_K	1.10	1.27	1.68	1.12	1.41	2.11	2.85
h_K	1	1	1	1	1	1	2

In the first five cases $M_K < 2$, so every class contains the ideal of norm 1, which is $\mathcal{O}_K$. For $\mathbb{Q}(\sqrt{-11})$, $M_K > 2$, but there is no ideal of norm 2, because 2 is inert (Theorem 6.34: $-11 \equiv 5 \pmod 8$); so again $h = 1$. For $\mathbb{Q}(\sqrt{-5})$ the ideals of norm ≤ 2 are $\mathcal{O}_K$ and $\mathfrak{p}_2$ of Example 6.18 (the norm 2 ideals are prime, Proposition 6.14(iv), and $\mathfrak{p}_2$ is the only prime above the ramified prime 2), which is not principal, and $\mathfrak{p}_2^2 = (2)$. Every class contains one of these two ideals, and they lie in different classes, so there are exactly two classes, and $h = 2$. Also $h(\mathbb{Q}(\sqrt{-23})) = 3$ (stated; PARI). For $\mathbb{Z}[i]$ and $\mathbb{Z}[\zeta_3]$ the class number one is also a consequence of the Euclidean algorithm (Chapter 2).

Example 6.18 ($\mathbb{Z}[\sqrt{-5}]$)**.** $R = \mathbb{Z}[\sqrt{-5}]$ is the ring of integers of $\mathbb{Q}(\sqrt{-5})$ ($-5 \equiv 3 \pmod 4$), with $D = -20$. In R, $6 = 2 \cdot 3 = (1 + \sqrt{-5})(1 - \sqrt{-5})$ are two factorisations into irreducibles,

no factor of one being associate to a factor of the other (Chapter 2). Put $\mathfrak{p}_2 = (2, 1+\sqrt{-5})$, $\mathfrak{p}_3 = (3, 1+\sqrt{-5})$, $\bar{\mathfrak{p}}_3 = (3, 1-\sqrt{-5})$. The ring homomorphisms $R \to \mathbb{F}_2$, $a+b\sqrt{-5} \mapsto a+b$, and $R \to \mathbb{F}_3$, $a+b\sqrt{-5} \mapsto a \mp b$ (well defined because $(\pm 1)^2 + 5 \equiv 0$ modulo 2, resp. 3), are surjective with kernels $\mathfrak{p}_2$, $\mathfrak{p}_3$, $\bar{\mathfrak{p}}_3$ (an element $a+b\sqrt{-5}$ with $a \equiv b \pmod 3$ is $b(1+\sqrt{-5})+(a-b) \in \mathfrak{p}_3$, and similarly for the others). So these are primes of norms $2, 3, 3$. Next, $\mathfrak{p}_2^2 = (4, 2+2\sqrt{-5}, -4+2\sqrt{-5})$ contains $6 = (2+2\sqrt{-5}) - (-4+2\sqrt{-5})$, hence 2, and is contained in (2): $\mathfrak{p}_2^2 = (2)$. Similarly $\mathfrak{p}_3\bar{\mathfrak{p}}_3 = (9, 3+3\sqrt{-5}, 3-3\sqrt{-5}, 6) = (3)$. Finally $1+\sqrt{-5} \in \mathfrak{p}_2 \cap \mathfrak{p}_3 = \mathfrak{p}_2\mathfrak{p}_3$ and both ideals have norm 6, so $(1+\sqrt{-5}) = \mathfrak{p}_2\mathfrak{p}_3$, and likewise $(1-\sqrt{-5}) = \mathfrak{p}_2\bar{\mathfrak{p}}_3$. Thus

$$(6) = \mathfrak{p}_2^2\,\mathfrak{p}_3\,\bar{\mathfrak{p}}_3,$$

and the two factorisations of 6 are two groupings of the same four prime ideals. None of $\mathfrak{p}_2, \mathfrak{p}_3, \bar{\mathfrak{p}}_3$ is principal: a generator would have norm $a^2+5b^2 \in \{2, 3\}$, which is impossible. This is the ideal-theoretic repair of Chapter 2, and the pattern is the one predicted by Theorem 6.20: $X^2+5 \equiv (X+1)^2 \pmod 2$ and $\equiv (X-1)(X+1) \pmod 3$.

The example already shows the three ways a rational prime can behave in a quadratic ring: 2 becomes a square of a prime, 3 a product of two distinct primes, and 11 stays prime (as X^2+5 is irreducible modulo 11: $-5 \equiv 6$ is not among the squares $1, 3, 4, 5, 9$ modulo 11). The next section turns this into a general theory: how $p\mathcal{O}_K$ factors, how to read the factorisation off a polynomial, which primes ramify, and how a Galois group acts on the primes above p.

6.3 Splitting of primes, ramification and Frobenius

This section explains how a prime of K factors in an extension L, defines the decomposition and inertia groups and the Frobenius element, and proves, given the tame relation (sketched here, proved in Chapter 7), the form of it that the paper uses. The paper's Section 1.1 is written in terms of I_p, Frob_p and V^{I_p} (Proposition 6.30); its local L-factors use the geometric Frobenius (Convention 6.25); Lemma lem:old uses the Frobenius at unramified primes and Chebotarev (Proposition 6.27, Section 6.6); Lemmas lem:IV and lem:euler use that a Frobenius at a tamely ramified prime q conjugates inertia to its q-th power (Corollary 6.32). The results on Frobenius elements are the black boxes that Chapter 5 states.

Theorem 6.19 ($\sum e_i f_i = n$)**.** *Let L/K be an extension of number fields of degree n, $\mathfrak{p}$ a nonzero prime of $\mathcal{O}_K$, and $\mathfrak{p}\mathcal{O}_L = \mathfrak{P}_1^{e_1} \cdots \mathfrak{P}_g^{e_g}$ with distinct primes $\mathfrak{P}_i$ (Theorem 6.13). The $\mathfrak{P}_i$ are exactly the primes $\mathfrak{P}$ of $\mathcal{O}_L$ with $\mathfrak{P} \cap \mathcal{O}_K = \mathfrak{p}$ ("$\mathfrak{P}$ lies above $\mathfrak{p}$", $\mathfrak{P} \mid \mathfrak{p}$). With the* ramification index *$e_i = e(\mathfrak{P}_i \mid \mathfrak{p})$ and the* residue degree *$f_i = f(\mathfrak{P}_i \mid \mathfrak{p}) = [\mathcal{O}_L/\mathfrak{P}_i : \mathcal{O}_K/\mathfrak{p}]$,*

$$\sum_{i=1}^{g} e_i f_i = n.$$

$\mathfrak{p}$ is ramified *in L if some $e_i > 1$ and* unramified *otherwise;* totally ramified *if $g = 1$, $e_1 = n$;* inert *if $g = 1$, $f_1 = n$;* split completely *if $g = n$. For a quadratic L/K each $\mathfrak{p}$ is exactly one of ramified, inert, split. In a tower $K \subseteq M \subseteq L$ with $\mathfrak{P} \mid \mathfrak{q} \mid \mathfrak{p}$: $e(\mathfrak{P} \mid \mathfrak{p}) = e(\mathfrak{P} \mid \mathfrak{q})e(\mathfrak{q} \mid \mathfrak{p})$ and $f(\mathfrak{P} \mid \mathfrak{p}) = f(\mathfrak{P} \mid \mathfrak{q})f(\mathfrak{q} \mid \mathfrak{p})$.*

Proof. A prime $\mathfrak{P}$ of $\mathcal{O}_L$ contains $\mathfrak{p}\mathcal{O}_L$ iff $\mathfrak{P} \cap \mathcal{O}_K \supseteq \mathfrak{p}$ iff $\mathfrak{P} \cap \mathcal{O}_K = \mathfrak{p}$ (the left side is a prime of $\mathcal{O}_K$, nonzero as it contains $\mathfrak{P} \cap \mathbb{Z}$, hence maximal), and $\mathfrak{P} \supseteq \mathfrak{p}\mathcal{O}_L$ iff $\mathfrak{P}$ divides $\mathfrak{p}\mathcal{O}_L$ (Theorem 6.13(iii)).

Let $\kappa = \mathcal{O}_K/\mathfrak{p}$. By Proposition 6.15(i), $\mathcal{O}_L/\mathfrak{p}\mathcal{O}_L \simeq \prod_i \mathcal{O}_L/\mathfrak{P}_i^{e_i}$, and $\mathcal{O}_L/\mathfrak{P}_i^{e_i}$ has a filtration with e_i quotients $\mathfrak{P}_i^k/\mathfrak{P}_i^{k+1} \simeq \mathcal{O}_L/\mathfrak{P}_i$, each of dimension f_i over κ; so $\dim_\kappa \mathcal{O}_L/\mathfrak{p}\mathcal{O}_L = \sum e_i f_i$. To see that this dimension is n, let $S = \mathcal{O}_K \setminus \mathfrak{p}$ and $A = S^{-1}\mathcal{O}_K$, a discrete valuation ring (Proposition 6.15(iv)), hence a PID. $B = S^{-1}\mathcal{O}_L$ is a finitely generated torsion-free A-module ($\mathcal{O}_L$ is finitely generated over $\mathbb{Z}$), hence free (Chapter 3), of rank n because $B \otimes_A K = L$ (Proposition 6.3). So $B/\mathfrak{p}B \simeq \kappa^n$. Finally $\mathcal{O}_L/\mathfrak{p}\mathcal{O}_L \to B/\mathfrak{p}B$ is an isomorphism: every $s \in S$ has an inverse s' modulo $\mathfrak{p}$, so $x/s \equiv s'x$ (surjectivity), and if $x \in \mathcal{O}_L$ and $sx \in \mathfrak{p}\mathcal{O}_L$ with $s \in S$, then $x = s'sx - (ss'-1)x \in \mathfrak{p}\mathcal{O}_L$ (injectivity). For $K = \mathbb{Q}$ this is simply $\mathcal{O}_L \simeq \mathbb{Z}^n$. A quadratic L/K has $\sum e_i f_i = 2$, so (e, f, g) is $(2,1,1)$, $(1,2,1)$ or $(1,1,2)$. In a tower, substitute $\mathfrak{q}\mathcal{O}_L = \prod \mathfrak{P}^{e(\mathfrak{P}|\mathfrak{q})}$ into $\mathfrak{p}\mathcal{O}_M = \prod \mathfrak{q}^{e(\mathfrak{q}|\mathfrak{p})}$ and use uniqueness; the residue degrees multiply as degrees of the tower of residue fields. □

Theorem 6.20 (Dedekind-Kummer)**.** *Let $K = \mathbb{Q}(\theta)$ with $\theta \in \mathcal{O}_K$ of minimal polynomial $g \in \mathbb{Z}[X]$, and let p be a prime with $p \nmid [\mathcal{O}_K : \mathbb{Z}[\theta]]$ (for instance $p^2 \nmid \operatorname{disc}(g)$, by Theorem 6.6(iii)). Let $\bar{g} = \bar{g}_1^{e_1} \cdots \bar{g}_r^{e_r}$ be the factorisation of $g \bmod p$ into distinct monic irreducibles of $\mathbb{F}_p[X]$, and $g_i \in \mathbb{Z}[X]$ monic lifts of $\bar{g}_i$. Then $\mathfrak{P}_i = (p, g_i(\theta))$ are distinct primes, $f(\mathfrak{P}_i \mid p) = \deg \bar{g}_i$, and*

$$p\mathcal{O}_K = \mathfrak{P}_1^{e_1} \cdots \mathfrak{P}_r^{e_r}.$$

The same holds for a relative extension $L = K(\theta)$, $\theta \in \mathcal{O}_L$, and a prime $\mathfrak{p}$ of $\mathcal{O}_K$ prime to the conductor $\{x \in \mathcal{O}_L : x\mathcal{O}_L \subseteq \mathcal{O}_K[\theta]\}$ (stated; [142, Chapter I, Proposition 8.3]).

Proof. Let $m = [\mathcal{O}_K : \mathbb{Z}[\theta]]$, prime to p. The inclusion induces $\mathbb{Z}[\theta]/p\mathbb{Z}[\theta] \to \mathcal{O}_K/p\mathcal{O}_K$. It is injective: if $x \in \mathbb{Z}[\theta]$ and $x = py$ with $y \in \mathcal{O}_K$, then $my \in \mathbb{Z}[\theta]$, and with $um + vp = 1$, $y = u(my) + vx \in \mathbb{Z}[\theta]$. Both sides have p^n elements, so it is an isomorphism, and $\mathbb{Z}[\theta]/p \simeq \mathbb{Z}[X]/(p, g) \simeq \mathbb{F}_p[X]/(\bar{g})$. By the Chinese remainder theorem in $\mathbb{F}_p[X]$,

$$A := \mathcal{O}_K/p\mathcal{O}_K \simeq \mathbb{F}_p[X]/(\bar{g}) \simeq \prod_i \mathbb{F}_p[X]/(\bar{g}_i^{e_i}),$$

whose maximal ideals are the $(\bar{g}_i)$, with residue fields $\mathbb{F}_p[X]/(\bar{g}_i)$ of degree $\deg \bar{g}_i$. The primes of $\mathcal{O}_K$ containing p correspond to the maximal ideals of A; the one corresponding to $(\bar{g}_i)$ is the preimage of $(\bar{g}_i(X))$, which is $\mathfrak{P}_i = (p, g_i(\theta))$. So these are the primes above p, distinct, with $f(\mathfrak{P}_i \mid p) = \deg \bar{g}_i$. In A, $\prod_i (\bar{g}_i)^{e_i} = (\bar{g}) = 0$, so $\prod_i \mathfrak{P}_i^{e_i} \subseteq p\mathcal{O}_K$; writing $p\mathcal{O}_K = \prod_i \mathfrak{P}_i^{a_i}$, this says $a_i \le e_i$ (Theorem 6.13(iii)), while $\sum a_i f_i = n = \deg g = \sum e_i f_i$ (Theorem 6.19). Hence $a_i = e_i$. □

Example 6.21 (worked factorisations)**.** All of the following factorisations were checked with PARI. (a) $\mathbb{Q}(i)$, $g = X^2 + 1$, index 1. Modulo 2, $g \equiv (X+1)^2$: $2\mathbb{Z}[i] = (2, 1+i)^2 = (1+i)^2$, and indeed $2 = -i(1+i)^2$. Modulo 5, $g \equiv (X-2)(X+2)$: $5\mathbb{Z}[i] = (5, i-2)(5, i+2) = (2-i)(2+i)$. Modulo 3, g is irreducible: 3 is inert, with residue field $\mathbb{F}_9$. (b) $\mathbb{Q}(\zeta_3)$, $g = X^2 + X + 1$, index 1. Modulo 3, $g \equiv (X-1)^2$: $3\mathbb{Z}[\zeta_3] = (3, \zeta_3 - 1)^2 = (1-\zeta_3)^2$. Modulo 7, $g \equiv (X-2)(X-4)$: $7 = (7, \zeta_3 - 2)(7, \zeta_3 - 4)$, and these ideals are $(2-\zeta_3)$ and $(2-\zeta_3^2)$, of norm $4+2+1 = 7$, with $(2-\zeta_3)(2-\zeta_3^2) = 7$ (note $\zeta_3^2 = -1-\zeta_3 \equiv 4$ when $\zeta_3 \equiv 2$). Modulo 2 and 5, g is irreducible: 2 and 5 are inert, with residue fields $\mathbb{F}_4$ and $\mathbb{F}_{25}$. (c) $\mathbb{Q}(\sqrt{-5})$: Example 6.18. (d) The index matters. In $K = \mathbb{Q}(\sqrt{-7})$, $\mathcal{O}_K = \mathbb{Z}[\theta]$ with $\theta = \frac{1+\sqrt{-7}}{2}$, $g = X^2 - X + 2$, and $[\mathcal{O}_K : \mathbb{Z}[\sqrt{-7}]] = 2$. Modulo 2, $X^2 + 7 \equiv (X+1)^2$ would wrongly suggest that 2 ramifies; but $X^2 - X + 2 \equiv X(X-1) \pmod 2$, so 2 splits: $2 = \frac{1+\sqrt{-7}}{2} \cdot \frac{1-\sqrt{-7}}{2}$, and indeed $2 \nmid d_K = -7$ (Theorem 6.22). (e) A non-Galois cubic. $K = \mathbb{Q}(2^{1/3})$ has $\mathcal{O}_K = \mathbb{Z}[2^{1/3}]$ and $d_K = \operatorname{disc}(X^3 - 2) = -108 = -2^2 \cdot 3^3$ (stated; PARI's

`nfbasis`; the index is prime to 5, 7 and 31 since disc is divisible only by 2 and 3). Modulo 5, $X^3-2\equiv(X+2)(X^2+3X+4)$ with the quadratic irreducible, so $5\mathcal{O}_K=\mathfrak{P}_1\mathfrak{P}_2$ with $f=1$ and $f=2$; modulo 7, X^3-2 is irreducible (2 is not a cube modulo 7), so 7 is inert; modulo 31 it has three roots $(4,7,20)$, so 31 splits completely. At 2 and 3 PARI finds $2\mathcal{O}_K=\mathfrak{P}^3$ and $3\mathcal{O}_K=\mathfrak{P}^3$, totally ramified ($X^3-2\equiv X^3$, resp. $(X+1)^3$, consistently with this, although the theorem applies at 2 and 3 only once the index is known to be 1). Unequal residue degrees above 5 cannot occur in a Galois extension (Proposition 6.23).

Theorem 6.22 (Dedekind's discriminant theorem)**.** *A prime p ramifies in the number field K if and only if $p\mid d_K$. Hence only finitely many primes ramify in K, and at least one does if $K\neq\mathbb{Q}$ (Theorem 6.16). For an extension L/K, a prime $\mathfrak{p}$ of K ramifies in L iff $\mathfrak{p}$ divides the relative discriminant ideal $\mathfrak{d}_{L/K}$ (stated; [142, Chapter III, Section 2]).*

Proof. Let $\beta_1,\dots,\beta_n$ be an integral basis and $A=\mathcal{O}_K/p\mathcal{O}_K$, with $\mathbb{F}_p$-basis $\bar\beta_i$. The matrix of multiplication by $\bar x$ on A is the reduction of the matrix of m_x, so $\mathrm{Tr}_{A/\mathbb{F}_p}(\bar x)=\mathrm{Tr}_{K/\mathbb{Q}}(x) \bmod p$ and $d_K \bmod p = \det(\mathrm{Tr}_{A/\mathbb{F}_p}(\bar\beta_i\bar\beta_j))$. Thus $p\mid d_K$ iff the trace form of the $\mathbb{F}_p$-algebra A is degenerate. By Proposition 6.15, $A\simeq\prod_i A_i$ with $A_i=\mathcal{O}_K/\mathfrak{P}_i^{e_i}$, and the trace form of A is the orthogonal sum of those of the A_i. If some $e_i>1$, A_i contains a nonzero nilpotent x (the image of an element $\xi\in\mathfrak{P}_i\setminus\mathfrak{P}_i^{e_i}$, nonzero in A_i, with $\xi^{e_i}\in\mathfrak{P}_i^{e_i}$); then xy is nilpotent for all y (A is commutative), multiplication by a nilpotent element is a nilpotent endomorphism, a nilpotent endomorphism has trace 0 (its only eigenvalue is 0), and x lies in the kernel of the trace form. If all $e_i=1$, each $A_i=\mathbb{F}_{p^{f_i}}$ is a field, whose trace form over $\mathbb{F}_p$ is nondegenerate: $\mathrm{Tr}(x)=x+x^p+\cdots+x^{p^{f-1}}$ (the sum of the conjugates, as in Proposition 6.5(i), the Galois group being generated by $x\mapsto x^p$, Chapter 2) is a polynomial function of degree $p^{f-1}<p^f$, hence not identically zero (a nonzero polynomial of degree $<p^f$ cannot vanish at all p^f elements of the field), and if $\mathrm{Tr}(xy)=0$ for all y with $x\neq0$ then, as xy runs over the whole field when y does, Tr would vanish identically. □

For example, for $K=\mathbb{Q}(i)$ and $p=2$ the algebra is $A=\mathbb{F}_2[X]/(X+1)^2$, the nilpotent is $x=1+i$, and the Gram matrix of the trace form in the basis $1,i$ is $\left(\begin{smallmatrix}2&0\\0&-2\end{smallmatrix}\right)$, zero modulo 2; for $p=3$, $A=\mathbb{F}_9$ and the same matrix is invertible modulo 3. The theorem says that this mechanism, nilpotents killing the trace form, is the whole story.

From now on in this section L/K is a *Galois* extension of number fields with group G, $\mathfrak{p}$ is a nonzero prime of K and $\mathfrak{P}\mid\mathfrak{p}$. Write $\kappa(\mathfrak{p})=\mathcal{O}_K/\mathfrak{p}$ and $\kappa(\mathfrak{P})=\mathcal{O}_L/\mathfrak{P}$, finite fields with $\#\kappa(\mathfrak{p})=N\mathfrak{p}$. Every $\sigma\in G$ maps $\mathcal{O}_L$ to itself and primes above $\mathfrak{p}$ to primes above $\mathfrak{p}$.

Proposition 6.23 (decomposition and inertia groups)**.** *(i) G acts transitively on the primes of L above $\mathfrak{p}$. Hence all $e(\mathfrak{P}\mid\mathfrak{p})=e$ are equal, all $f(\mathfrak{P}\mid\mathfrak{p})=f$ are equal, and $efg=n=\#G$. (ii) The* decomposition group $D_\mathfrak{P}=\{\sigma\in G:\sigma\mathfrak{P}=\mathfrak{P}\}$ *is the stabiliser of $\mathfrak{P}$ (Chapter 1); each $\sigma\in D_\mathfrak{P}$ induces an automorphism $\bar\sigma$ of $\kappa(\mathfrak{P})$ over $\kappa(\mathfrak{p})$, and the* inertia group $I_\mathfrak{P}=\{\sigma\in D_\mathfrak{P}:\sigma(x)\equiv x \pmod{\mathfrak{P}}$ *for all $x\in\mathcal{O}_L$}$\}$ *is the kernel of $\sigma\mapsto\bar\sigma$, a normal subgroup of $D_\mathfrak{P}$. Moreover $[G:D_\mathfrak{P}]=g$, $\#D_\mathfrak{P}=ef$, $D_{\sigma\mathfrak{P}}=\sigma D_\mathfrak{P}\sigma^{-1}$ and $I_{\sigma\mathfrak{P}}=\sigma I_\mathfrak{P}\sigma^{-1}$; if G is abelian, $D_\mathfrak{P}$ and $I_\mathfrak{P}$ depend only on $\mathfrak{p}$.*

Proof. (i) Suppose $\mathfrak{P}'\mid\mathfrak{p}$ and $\mathfrak{P}'\neq\sigma\mathfrak{P}$ for all $\sigma\in G$. By the Chinese remainder theorem there is $x\in\mathcal{O}_L$ with $x\in\mathfrak{P}'$ and $x\equiv1 \pmod{\sigma\mathfrak{P}}$ for all σ. The norm $N_{L/K}(x)=\prod_{\sigma\in G}\sigma(x)$ is fixed by G and integral, so lies in $\mathcal{O}_K$; it lies in $\mathfrak{P}'$ (the factor x does), so in $\mathfrak{P}'\cap\mathcal{O}_K=\mathfrak{p}\subseteq\mathfrak{P}$. As $\mathfrak{P}$ is prime, some $\sigma(x)\in\mathfrak{P}$, that is $x\in\sigma^{-1}\mathfrak{P}$, contradicting $x\equiv1 \pmod{\sigma^{-1}\mathfrak{P}}$. Each σ induces an

isomorphism $\mathcal{O}_L/\mathfrak{P} \simeq \mathcal{O}_L/\sigma\mathfrak{P}$ over $\kappa(\mathfrak{p})$, and applying σ to $\mathfrak{p}\mathcal{O}_L = \prod \mathfrak{P}_i^{e_i}$ permutes the factors keeping exponents; so e and f are constant on the orbit, which is everything, and Theorem 6.19 gives $efg = n$. (ii) Orbit-stabiliser (Chapter 1) gives $[G : D_{\mathfrak{P}}] = g$, so $\#D_{\mathfrak{P}} = n/g = ef$. A kernel is normal. $\tau \in I_{\mathfrak{P}}$ iff $\tau x - x \in \mathfrak{P}$ for all x iff $(\sigma\tau\sigma^{-1})(\sigma x) - \sigma x \in \sigma\mathfrak{P}$ for all x iff $\sigma\tau\sigma^{-1} \in I_{\sigma\mathfrak{P}}$; the same for D. If G is abelian, conjugation is trivial, and transitivity gives the last claim. □

The smallest example shows all three behaviours. Let $L = \mathbb{Q}(i)$, $K = \mathbb{Q}$, $G = \{1, c\}$ with c complex conjugation (Example 6.21(a)). At $p = 5$, $5 = (2+i)(2-i)$ and c exchanges the two primes, so $g = 2$ and $D_{\mathfrak{P}} = I_{\mathfrak{P}} = 1$. At $p = 3$, (3) is prime with residue field $\mathbb{F}_9$, so $g = 1$, $f = 2$ and $D_{\mathfrak{P}} = G$; and c induces the nontrivial automorphism of $\mathbb{F}_9 = \mathbb{F}_3(i)$, as $c(i) = -i \neq i$ modulo 3, so $I_{\mathfrak{P}} = 1$. At $p = 2$, $(2) = (1+i)^2$, so $e = 2$, $D_{\mathfrak{P}} = G$, and c acts trivially on $\mathbb{Z}[i]/(1+i) = \mathbb{F}_2$, so $I_{\mathfrak{P}} = G$. In each case $\#D_{\mathfrak{P}} = ef$.

Theorem 6.24 (the residue field extension)**.** *In this situation:*

(i) The homomorphism $D_{\mathfrak{P}} \to \mathrm{Gal}(\kappa(\mathfrak{P})/\kappa(\mathfrak{p}))$, $\sigma \mapsto \bar{\sigma}$, is surjective with kernel $I_{\mathfrak{P}}$. Hence $\#I_{\mathfrak{P}} = e$, and $D_{\mathfrak{P}}/I_{\mathfrak{P}}$ is cyclic of order f, generated by the class of any σ with $\bar{\sigma} = (x \mapsto x^{N\mathfrak{p}})$.

(ii) For $K \subseteq M \subseteq L$ with $H = \mathrm{Gal}(L/M)$ and $\mathfrak{q} = \mathfrak{P} \cap M$: $D_{\mathfrak{P}}(L/M) = D_{\mathfrak{P}} \cap H$ and $I_{\mathfrak{P}}(L/M) = I_{\mathfrak{P}} \cap H$; if M/K is Galois, the images of $D_{\mathfrak{P}}$ and $I_{\mathfrak{P}}$ in $G/H = \mathrm{Gal}(M/K)$ are $D_{\mathfrak{q}}$ and $I_{\mathfrak{q}}$.

(iii) $\mathfrak{p}$ splits completely in L iff $D_{\mathfrak{P}} = 1$, and $\mathfrak{p}$ is unramified in L iff $I_{\mathfrak{P}} = 1$.

Proof. (i) $\kappa(\mathfrak{P})/\kappa(\mathfrak{p})$ is an extension of finite fields of degree f, Galois with cyclic group generated by $x \mapsto x^{N\mathfrak{p}}$ (Chapter 2). Choose $\bar{\theta}$ generating the cyclic group $\kappa(\mathfrak{P})^\times$, so $\kappa(\mathfrak{P}) = \kappa(\mathfrak{p})(\bar{\theta})$, and by the Chinese remainder theorem a lift $\theta \in \mathcal{O}_L$ of $\bar{\theta}$ lying in every $\tau\mathfrak{P} \neq \mathfrak{P}$. The polynomial $h(X) = \prod_{\sigma \in G}(X - \sigma\theta)$ has coefficients in $\mathcal{O}_K$, and its reduction $\bar{h} = \prod_\sigma (X - \overline{\sigma\theta})$ modulo $\mathfrak{P}$ has coefficients in $\kappa(\mathfrak{p})$ and the root $\bar{\theta}$; so $\bar{\theta}^{N\mathfrak{p}}$ is also a root: $\bar{\theta}^{N\mathfrak{p}} = \overline{\sigma\theta}$ for some σ. Since $\bar{\theta}^{N\mathfrak{p}} \neq 0$, $\sigma\theta \notin \mathfrak{P}$, so $\theta \notin \sigma^{-1}\mathfrak{P}$, which forces $\sigma^{-1}\mathfrak{P} = \mathfrak{P}$: $\sigma \in D_{\mathfrak{P}}$, and $\bar{\sigma}(\bar{\theta}) = \bar{\theta}^{N\mathfrak{p}}$, so $\bar{\sigma}$ is the generator $x \mapsto x^{N\mathfrak{p}}$. The image is therefore everything; the kernel is $I_{\mathfrak{P}}$ by definition, and $\#I_{\mathfrak{P}} = ef/f = e$. (ii) The first two equalities hold by definition. Restriction maps $D_{\mathfrak{P}}$ into $D_{\mathfrak{q}}$ and $I_{\mathfrak{P}}$ into $I_{\mathfrak{q}}$, with kernels $D_{\mathfrak{P}} \cap H$ and $I_{\mathfrak{P}} \cap H$, of orders $e(\mathfrak{P} \mid \mathfrak{q})f(\mathfrak{P} \mid \mathfrak{q})$ and $e(\mathfrak{P} \mid \mathfrak{q})$ by (i) for L/M. So the images have orders $e(\mathfrak{q} \mid \mathfrak{p})f(\mathfrak{q} \mid \mathfrak{p}) = \#D_{\mathfrak{q}}$ and $e(\mathfrak{q} \mid \mathfrak{p}) = \#I_{\mathfrak{q}}$ (Theorem 6.19, and (i) for M/K). (iii) $D_{\mathfrak{P}} = 1$ iff $ef = 1$ iff $g = n$; $I_{\mathfrak{P}} = 1$ iff $e = 1$. □

Convention 6.25 (arithmetic and geometric Frobenius)**.** For $\mathfrak{P}$ unramified over $\mathfrak{p}$, the *arithmetic Frobenius* $\mathrm{Frob}_{\mathfrak{P}}$ is the element of Proposition 6.27, characterised by $\mathrm{Frob}_{\mathfrak{P}}(x) \equiv x^{N\mathfrak{p}} \pmod{\mathfrak{P}}$; its inverse is the *geometric Frobenius*. The book writes Frob_p for an arithmetic Frobenius at p (Proposition 6.30), as Chapter 5 does and as the paper does (Section 1.1: "Frob_p is an arithmetic Frobenius at p and Frob_p^{-1} a geometric one"). So Frob_p acts on μ_n ($p \nmid n$) by $\zeta \mapsto \zeta^p$, $\chi_\ell(\mathrm{Frob}_p) = p$, $\bar{\chi}_\ell(\mathrm{Frob}_p) = p \bmod \ell$, and for $E/\mathbb{Q}$ with good reduction at $p \neq \ell$ the characteristic polynomial of $\rho_{E,\ell}(\mathrm{Frob}_p)$ on $V_\ell E$ is $X^2 - a_p X + p$ (Chapters 9 and 11). Local L-factors of a representation V of $G_{\mathbb{Q}}$ on a finite-dimensional $\mathbb{Q}_\ell$-vector space are written with the geometric Frobenius:

$$L_p(V, s) = \det(1 - \mathrm{Frob}_p^{-1}\, p^{-s} \mid V^{I_p})^{-1} \qquad (p \neq \ell),$$

so that $L_p(\mathbb{Q}_\ell(1), s) = (1 - p^{-1-s})^{-1}$ and $L_p(V(1), s) = L_p(V, s+1)$, as $\chi_\ell(\mathrm{Frob}_p^{-1}) = p^{-1}$. On $V_\ell E$ the geometric Frobenius has the eigenvalues α^{-1}, β^{-1} (with $\alpha + \beta = a_p$, $\alpha\beta = p$), and on

the dual $V_\ell E^\vee$ it has α, β, so $L_p(V_\ell E^\vee, s) = (1 - a_p p^{-s} + p^{1-2s})^{-1}$ is the Euler factor of $L(E, s)$. *Dictionary.* When the multiset of Frobenius eigenvalues on V^{I_p} is stable under inversion, the two conventions give the same factor: this is the case for $\mathrm{ad}^0 V$ at a good prime (eigenvalues $\alpha/\beta, 1, \beta/\alpha$) and on the lines on which Frobenius acts by ± 1 (types II, III, IV and their duals). When it is not stable they differ: if E has multiplicative reduction at q, $(\mathrm{ad}^0 V)^{I_q}$ is a line on which the arithmetic Frobenius acts by q and the geometric one by q^{-1} (Example 6.26), and the factor $1 - q^{-1-s}$ of the paper's table requires the geometric one.

The two identities in the convention are short computations. On $V(1) = V \otimes \chi_\ell$ the geometric Frobenius acts as $p^{-1}\,\mathrm{Frob}_p^{-1}$, and twisting by the character χ_ℓ, unramified at $p \neq \ell$, does not change the inertia invariants; so $\det(1 - p^{-1}\,\mathrm{Frob}_p^{-1}\,p^{-s} \mid V^{I_p}) = \det(1 - \mathrm{Frob}_p^{-1}\,p^{-(s+1)} \mid V^{I_p})$, which is $L_p(V(1), s) = L_p(V, s+1)$. On the dual $V_\ell E^\vee$ an element g acts by the inverse transpose of $\rho(g)$; so Frob_p^{-1} acts by the transpose of $\rho(\mathrm{Frob}_p)$, whose eigenvalues are α, β, and $\det(1 - \mathrm{Frob}_p^{-1}\,p^{-s} \mid V_\ell E^\vee) = (1 - \alpha p^{-s})(1 - \beta p^{-s}) = 1 - a_p p^{-s} + p^{1-2s}$. With the arithmetic Frobenius on $V_\ell E^\vee$ one would get $(1 - \alpha^{-1} p^{-s})(1 - \beta^{-1} p^{-s}) = 1 - \frac{a_p}{p} p^{-s} + p^{-1-2s}$ instead, which is not the Euler factor of $L(E, s)$: this is why the choice matters.

Example 6.26 (the multiplicative case)**.** Let E have split multiplicative reduction at $q \neq \ell$. In a suitable basis e_1, e_2 of $T_\ell E$ (Chapter 10), inertia acts through $\left(\begin{smallmatrix} 1 & * \\ 0 & 1 \end{smallmatrix}\right)$ with a nonzero corner, and an arithmetic Frobenius through $\rho(\mathrm{Frob}) = \left(\begin{smallmatrix} q & c' \\ 0 & 1 \end{smallmatrix}\right)$. On $\mathrm{ad}^0 V$, with basis $e = e_1 \otimes e_2^\vee$, h, f (Chapter 4), the invariants of a nontrivial unipotent $u = \left(\begin{smallmatrix} 1 & t \\ 0 & 1 \end{smallmatrix}\right)$, $t \neq 0$, form the line $\mathbb{Q}_\ell e$. Indeed, with $e = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, $h = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$, $f = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$, a direct multiplication gives

$$ueu^{-1} = e, \qquad uhu^{-1} = h - 2te, \qquad ufu^{-1} = f + th - t^2 e,$$

so $xe + yh + zf$ is sent to $(x - 2ty - t^2 z)e + (y + tz)h + zf$, and it is fixed iff $tz = 0$ and $2ty + t^2 z = 0$, that is $z = y = 0$ (as $t \neq 0$ and 2 is invertible). The image of inertia consists of such u, and contains one with $t \neq 0$, so $(\mathrm{ad}^0 V)^{I_q} = \mathbb{Q}_\ell e$. Next $\rho(\mathrm{Frob})\, e\, \rho(\mathrm{Frob})^{-1} = qe$: with $F = \left(\begin{smallmatrix} q & c' \\ 0 & 1 \end{smallmatrix}\right)$ and $F^{-1} = \left(\begin{smallmatrix} q^{-1} & -c'q^{-1} \\ 0 & 1 \end{smallmatrix}\right)$, $Fe = \left(\begin{smallmatrix} 0 & q \\ 0 & 0 \end{smallmatrix}\right)$ and $FeF^{-1} = \left(\begin{smallmatrix} 0 & q \\ 0 & 0 \end{smallmatrix}\right) = qe$ (in general conjugation by $\left(\begin{smallmatrix} a & * \\ 0 & d \end{smallmatrix}\right)$ scales e by a/d). So Frob acts on $(\mathrm{ad}^0 V)^{I_q}$ by q, and Frob^{-1} by q^{-1}: $\det(1 - \mathrm{Frob}_q^{-1}\, q^{-s} \mid (\mathrm{ad}^0 V)^{I_q}) = 1 - q^{-1-s}$, the entry of the paper's table, whereas the arithmetic Frobenius would give $1 - q^{1-s}$. The nonsplit case is the same, the unramified quadratic character ± 1 cancelling in the adjoint.

Proposition 6.27 (the Frobenius element)**.** *Let L/K be Galois with group G, $\mathfrak{p}$ unramified in L and $\mathfrak{P} \mid \mathfrak{p}$.*

(i) There is a unique $\mathrm{Frob}_\mathfrak{P} \in G$ *with* $\mathrm{Frob}_\mathfrak{P}(x) \equiv x^{N\mathfrak{p}} \pmod{\mathfrak{P}}$ *for all $x \in \mathcal{O}_L$; it lies in $D_\mathfrak{P}$, generates it, and has order f.*

(ii) $\mathrm{Frob}_{\sigma\mathfrak{P}} = \sigma\,\mathrm{Frob}_\mathfrak{P}\,\sigma^{-1}$*; so* $\{\mathrm{Frob}_\mathfrak{P} : \mathfrak{P} \mid \mathfrak{p}\}$ *is a conjugacy class of G, the* Frobenius class $\mathrm{Frob}_\mathfrak{p}$.

(iii) $\mathfrak{p}$ splits completely in L iff $\mathrm{Frob}_\mathfrak{p} = \{1\}$.

(iv) If G is abelian, $\mathrm{Frob}_\mathfrak{P}$ *depends only on $\mathfrak{p}$ and is written* $\mathrm{Frob}_\mathfrak{p} \in G$.

(v) If $K \subseteq M \subseteq L$ with M/K Galois, then $\mathrm{Frob}_\mathfrak{P}|_M = \mathrm{Frob}_{\mathfrak{P} \cap M}$. *If $K \subseteq K' \subseteq L$ and $\mathfrak{p}' = \mathfrak{P} \cap K'$ has residue degree f' over $\mathfrak{p}$, then* $\mathrm{Frob}_\mathfrak{P}(L/K') = \mathrm{Frob}_\mathfrak{P}(L/K)^{f'}$.

(vi) If $\mathfrak{p}$ is ramified, the elements of $D_{\mathfrak{P}}$ inducing $x \mapsto x^{N\mathfrak{p}}$ on $\kappa(\mathfrak{P})$ form a coset of $I_{\mathfrak{P}}$; each of them is called a Frobenius at $\mathfrak{P}$*, and there is no distinguished one.*

Proof. (i) By Theorem 6.24, $I_{\mathfrak{P}} = 1$ and $D_{\mathfrak{P}} \simeq \mathrm{Gal}(\kappa(\mathfrak{P})/\kappa(\mathfrak{p}))$, cyclic of order f; let $\mathrm{Frob}_{\mathfrak{P}}$ be the preimage of $x \mapsto x^{N\mathfrak{p}}$. If $\sigma \in G$ satisfies the congruence, then $\sigma(\mathfrak{P}) \subseteq \mathfrak{P}$ (take $x \in \mathfrak{P}$), so $\sigma\mathfrak{P} = \mathfrak{P}$ and $\sigma \in D_{\mathfrak{P}}$ induces $x \mapsto x^{N\mathfrak{p}}$: $\sigma = \mathrm{Frob}_{\mathfrak{P}}$. (ii) $\sigma\,\mathrm{Frob}_{\mathfrak{P}}\,\sigma^{-1}(x) = \sigma(\mathrm{Frob}_{\mathfrak{P}}(\sigma^{-1}x)) \equiv \sigma((\sigma^{-1}x)^{N\mathfrak{p}}) = x^{N\mathfrak{p}} \pmod{\sigma\mathfrak{P}}$, and use uniqueness; all primes above $\mathfrak{p}$ are conjugate. (iii) $\mathrm{Frob}_{\mathfrak{P}}$ generates $D_{\mathfrak{P}}$; use Theorem 6.24(iii). (iv) follows from (ii). (v) $\mathrm{Frob}_{\mathfrak{P}}|_M$ satisfies the defining congruence modulo $\mathfrak{P} \cap \mathcal{O}_M$ on $\mathcal{O}_M$, and $\mathfrak{P} \cap M$ is unramified over $\mathfrak{p}$ (Theorem 6.19); use uniqueness in $\mathrm{Gal}(M/K)$. For K': both elements lie in $D_{\mathfrak{P}}(L/K)$ (as $D_{\mathfrak{P}}(L/K') \subseteq D_{\mathfrak{P}}(L/K)$) and induce $x \mapsto x^{(N\mathfrak{p})^{f'}} = x^{N\mathfrak{p}'}$ on $\kappa(\mathfrak{P})$; $D_{\mathfrak{P}}(L/K) \to \mathrm{Gal}(\kappa(\mathfrak{P})/\kappa(\mathfrak{p}))$ is injective. (vi) is Theorem 6.24(i). □

Examples, proved in Theorem 6.49 and Proposition 6.35: in $\mathbb{Q}(\zeta_n)$, for $p \nmid n$, $\mathrm{Frob}_p = \sigma_p\colon \zeta_n \mapsto \zeta_n^p$; in $\mathbb{Q}(\sqrt{d})$ of discriminant D, for $p \nmid D$, $\mathrm{Frob}_p(\sqrt{d}) = (\frac{D}{p})\sqrt{d}$. The defining congruence can be checked by hand in $\mathbb{Q}(i)$: for an odd prime p and $x = a + bi \in \mathbb{Z}[i]$, $x^p \equiv a^p + b^p i^p \equiv a + b\,i^p \pmod{p}$ (binomial theorem modulo p and Fermat), and $i^p = (-1)^{(p-1)/2}i$. So Frob_p is the identity for $p \equiv 1 \pmod 4$ and complex conjugation for $p \equiv 3 \pmod 4$, matching the decomposition groups found after Proposition 6.23.

Proposition 6.28 (Frobenius and subfields)**.** *Let $L/\mathbb{Q}$ be finite Galois with group G, $H \leq G$, $M = L^H$, p a prime unramified in L, $\mathfrak{P} \mid p$ and $F = \mathrm{Frob}_{\mathfrak{P}}$. The map $\sigma H \mapsto \sigma^{-1}\mathfrak{P} \cap M$ induces a bijection from the orbits of $\langle F\rangle$ acting on G/H by left multiplication to the primes of M above p; the residue degree of the prime is the length of the orbit, and all ramification indices are* 1*.*

Proof. Every prime of M above p lies under a prime of L above p (Theorem 6.19 for L/M), and these are the $\tau\mathfrak{P}$, $\tau \in G$. Two of them, $\tau\mathfrak{P}$ and $\tau'\mathfrak{P}$, lie over the same prime of M iff they are conjugate under $H = \mathrm{Gal}(L/M)$ (Proposition 6.23(i) for L/M), iff $\tau' \in H\tau D$ with $D = D_{\mathfrak{P}} = \langle F\rangle$. So the primes of M above p correspond to the double cosets $H\backslash G/D$, and inversion $H\tau D \mapsto D\tau^{-1}H$ identifies these with the D-orbits on G/H; with $\sigma = \tau^{-1}$ this is the stated map. For $\mathfrak{q} = \tau\mathfrak{P} \cap M$: $D_{\tau\mathfrak{P}}(L/M) = \tau D\tau^{-1} \cap H$ has order $f(\tau\mathfrak{P} \mid \mathfrak{q})$ (all ramification is trivial), so $f(\mathfrak{q} \mid p) = f/\#(\tau D\tau^{-1} \cap H) = \#D/\#(D \cap \tau^{-1}H\tau)$, which is the length of the D-orbit of $\tau^{-1}H$ (its stabiliser in D is $D \cap \tau^{-1}H\tau$). □

Corollary 6.29 (Dedekind's theorem on cycle types)**.** *Let $f \in \mathbb{Z}[X]$ be separable of degree n with leading coefficient a, p a prime with $p \nmid a\,\mathrm{disc}(f)$, L the splitting field of f, and $d_1, \dots, d_r$ the degrees of the irreducible factors of f mod p in $\mathbb{F}_p[X]$. Then p is unramified in L, and for $\mathfrak{P} \mid p$ the permutation of the roots of f induced by $\mathrm{Frob}_{\mathfrak{P}}$ has cycle type $(d_1, \dots, d_r)$.*

Proof. Replacing f by $a^{n-1}f(X/a)$, whose roots are a times those of f, whose discriminant is a power of a times $\mathrm{disc}(f)$, and whose factorisation modulo p has the same degrees (a is invertible modulo p), we may assume f monic. Its roots $\beta_1, \dots, \beta_n$ lie in $\mathcal{O}_L$, and $\mathrm{disc}(f) = \prod_{i<j}(\beta_i - \beta_j)^2 \notin \mathfrak{P}$, so their reductions are distinct roots of $\bar{f}$ in $\kappa(\mathfrak{P})$: reduction is a bijection from the roots of f to the roots of $\bar{f}$, compatible with the action of $D_{\mathfrak{P}}$. An element of $I_{\mathfrak{P}}$ acts trivially on $\kappa(\mathfrak{P})$, so fixes each reduction, hence each β_i, hence L: $I_{\mathfrak{P}} = 1$ and p is unramified. $\mathrm{Frob}_{\mathfrak{P}}$ acts on the reductions as $x \mapsto x^p$, and the orbit of a root of $\bar{f}$ under $x \mapsto x^p$ consists of the roots of its irreducible factor over $\mathbb{F}_p$ (Chapter 2); so the cycles have lengths $d_1, \dots, d_r$. □

For example, in $\mathbb{Q}(2^{1/3})$ (Example 6.21(e)), $X^3-2 \equiv (X+2)(X^2+3X+4) \pmod 5$, so Frob_5 in $\mathrm{Gal}(\mathbb{Q}(2^{1/3},\zeta_3)/\mathbb{Q}) \simeq S_3$ is a transposition: it fixes one root and swaps the other two, and the primes above 5 in $\mathbb{Q}(2^{1/3})$ have residue degrees 1 and 2, the orbit lengths of Proposition 6.28. To see the dictionary concretely, take $H = \mathrm{Gal}(L/\mathbb{Q}(2^{1/3}))$, the stabiliser of the real root; then G/H is identified with the set of the three cube roots of 2, and $\langle \mathrm{Frob}_{\bar{\mathfrak{P}}} \rangle$-orbits on G/H are orbits on the roots. At $p = 31$, $X^3 - 2$ has three roots modulo 31, Frob is trivial, there are three orbits of length 1, and 31 splits completely in $\mathbb{Q}(2^{1/3})$; at $p = 7$ it is irreducible, Frob is a 3-cycle, there is one orbit of length 3, and 7 is inert, in agreement with Example 6.21(e).

Proposition 6.30 (Frobenius elements in $G_{\mathbb{Q}}$)**.** *Let p be a prime. A* prime of $\bar{\mathbb{Z}}$ above p *is a maximal ideal $\bar{\mathfrak{P}}$ of $\bar{\mathbb{Z}}$ containing p.*

(i) $\bar{\mathfrak{P}} \mapsto (\bar{\mathfrak{P}} \cap \mathcal{O}_L)_L$ is a bijection from the primes of $\bar{\mathbb{Z}}$ above p to the compatible families of primes above p in the finite Galois extensions $L/\mathbb{Q}$; $G_{\mathbb{Q}}$ acts transitively on them, and $\bar{\mathbb{Z}}/\bar{\mathfrak{P}} \simeq \overline{\mathbb{F}}_p$.

(ii) The decomposition group $D_{\bar{\mathfrak{P}}} = \{\sigma \in G_{\mathbb{Q}} : \sigma\bar{\mathfrak{P}} = \bar{\mathfrak{P}}\}$ *and the* inertia group $I_{\bar{\mathfrak{P}}}$ *(the kernel of the action of $D_{\bar{\mathfrak{P}}}$ on $\bar{\mathbb{Z}}/\bar{\mathfrak{P}}$) are closed subgroups, equal to $\varprojlim D_{\mathfrak{P}_L}$ and $\varprojlim I_{\mathfrak{P}_L}$, with surjective projections to $D_{\mathfrak{P}_L}$ and $I_{\mathfrak{P}_L}$ for every finite Galois L; for another choice $\sigma\bar{\mathfrak{P}}$ they are conjugated by σ. Once $\bar{\mathfrak{P}}$ is fixed we write D_p, I_p. The sequence $1 \to I_p \to D_p \to \mathrm{Gal}(\overline{\mathbb{F}}_p/\mathbb{F}_p) \to 1$ is exact, and $\mathrm{Gal}(\overline{\mathbb{F}}_p/\mathbb{F}_p) \simeq \hat{\mathbb{Z}}$ is topologically generated by $x \mapsto x^p$.*

(iii) A Frobenius at p *is any $\mathrm{Frob}_p \in D_p$ mapping to $x \mapsto x^p$; it is well defined up to I_p and, when $\bar{\mathfrak{P}}$ varies, up to conjugation in $G_{\mathbb{Q}}$. Its image in $\mathrm{Gal}(L/\mathbb{Q})$, for L finite Galois and unramified at p, lies in the class $\mathrm{Frob}_p(L/\mathbb{Q})$.*

(iv) A continuous representation ρ of $G_{\mathbb{Q}}$ is unramified at p *if $\rho(I_p) = 1$ for one, equivalently every, $\bar{\mathfrak{P}} \mid p$; then the conjugacy class of $\rho(\mathrm{Frob}_p)$, and in particular $\det(X - \rho(\mathrm{Frob}_p))$, is well defined. If ρ has finite image, with L the field cut out by ρ (the fixed field of $\ker\rho$), then ρ is unramified at p iff p is unramified in L, and $\rho(\mathrm{Frob}_p)$ is the image of the class $\mathrm{Frob}_p(L/\mathbb{Q})$.*

(v) (Stated; Chapter 7.) An embedding $\overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_p$ identifies $D_{\bar{\mathfrak{P}}}$, for the prime it defines, with $G_{\mathbb{Q}_p}$ and $I_{\bar{\mathfrak{P}}}$ with the inertia subgroup of $G_{\mathbb{Q}_p}$.

Proof. (i) $\bar{\mathfrak{P}} \cap \mathcal{O}_L$ is a prime of $\mathcal{O}_L$ containing p, and the family is compatible. Conversely the union of a compatible family is an ideal of $\bar{\mathbb{Z}} = \bigcup_L \mathcal{O}_L$ (a directed union) which is prime and contains p, and every nonzero prime of $\bar{\mathbb{Z}}$ is maximal (its trace on each $\mathcal{O}_L$ is). Given $\bar{\mathfrak{P}}, \bar{\mathfrak{P}}'$, the sets $S_L = \{\sigma \in \mathrm{Gal}(L/\mathbb{Q}) : \sigma\mathfrak{P}_L = \mathfrak{P}'_L\}$ are nonempty (Proposition 6.23) and finite, and restriction maps $S_{L'}$ into S_L for $L \subseteq L'$; an inverse limit of nonempty finite sets is nonempty (Chapter 5), and an element of it is a $\sigma \in G_{\mathbb{Q}}$ with $\sigma\bar{\mathfrak{P}} = \bar{\mathfrak{P}}'$. The residue ring $\bigcup_L \kappa(\mathfrak{P}_L)$ is an algebraic extension of $\mathbb{F}_p$; it contains every $\mathbb{F}_{p^f}$, since a root in $\bar{\mathbb{Z}}$ of a monic lift of an irreducible polynomial of degree f over $\mathbb{F}_p$ reduces to a root of that polynomial. (ii) By definition $D_{\bar{\mathfrak{P}}}$ is the set of σ whose restrictions lie in all $D_{\mathfrak{P}_L}$, which is the inverse limit, a closed subgroup; likewise for I. Surjectivity of the projections: for $L \subseteq L'$ the restriction maps $D_{\mathfrak{P}_{L'}} \to D_{\mathfrak{P}_L}$ and $I_{\mathfrak{P}_{L'}} \to I_{\mathfrak{P}_L}$ are surjective (Theorem 6.24(ii)), and the fibres over a given element form an inverse system of nonempty finite sets. The exact sequence is the inverse limit of those of Theorem 6.24(i), surjectivity again by compactness; and $\mathrm{Gal}(\overline{\mathbb{F}}_p/\mathbb{F}_p) = \varprojlim \mathbb{Z}/f \simeq \hat{\mathbb{Z}}$ (Chapter 5). (iii) follows from (ii) and Proposition 6.27. (iv) Inertia groups for different $\bar{\mathfrak{P}}$ are conjugate.

If $\rho(I_p) = 1$, two Frobenius elements differ by I_p and conjugation, so $\rho(\mathrm{Frob}_p)$ is defined up to conjugacy. If ρ factors through $\mathrm{Gal}(L/\mathbb{Q})$ injectively, then $\rho(I_p)$ is the image of $I_{\mathfrak{P}_L}$ by (ii), trivial iff p is unramified in L, and the image of Frob_p is $\mathrm{Frob}_{\mathfrak{P}_L}$. (v) We do not prove this here; see Chapter 7. □

Proposition 6.31 (tame inertia)**.** *Let L/K be finite Galois, $\mathfrak{P} \mid \mathfrak{p}$, p the residue characteristic, and suppose that $\#I_{\mathfrak{P}}$ is prime to p ($\mathfrak{P}$ is* tamely ramified*). Then $I_{\mathfrak{P}}$ is cyclic, and for every $F \in D_{\mathfrak{P}}$ inducing $x \mapsto x^{N\mathfrak{p}}$ on $\kappa(\mathfrak{P})$ and every $\tau \in I_{\mathfrak{P}}$,*

$$F\tau F^{-1} = \tau^{N\mathfrak{p}}.$$

Sketch of proof. Let ϖ be a uniformiser of the discrete valuation ring $\mathcal{O}_{L,\mathfrak{P}}$ (Proposition 6.15(iv)), on which $D_{\mathfrak{P}}$ acts. For $\tau \in I_{\mathfrak{P}}$, $\tau(\varpi)$ is again a uniformiser, so $\tau(\varpi)/\varpi$ is a unit; put $\theta(\tau) = \tau(\varpi)/\varpi \bmod \mathfrak{P} \in \kappa(\mathfrak{P})^\times$. Since τ acts trivially modulo $\mathfrak{P}$ on $\mathcal{O}_{L,\mathfrak{P}}$ (the congruence $\tau x \equiv x$ extends from $\mathcal{O}_L$ to fractions with denominators prime to $\mathfrak{P}$), θ does not depend on ϖ (replacing ϖ by $u\varpi$ multiplies by $\tau(u)/u \equiv 1$) and is a homomorphism: for $\sigma, \tau \in I_{\mathfrak{P}}$, $\sigma\tau(\varpi)/\varpi = \sigma(\tau(\varpi)/\varpi) \cdot \sigma(\varpi)/\varpi$, and σ fixes the unit $\tau(\varpi)/\varpi$ modulo $\mathfrak{P}$, so $\theta(\sigma\tau) \equiv \theta(\tau)\theta(\sigma)$. The kernel of θ is the first ramification group, which is a p-group; this is the step we do not prove (it uses the filtration of $I_{\mathfrak{P}}$ by the higher ramification groups, whose successive quotients embed in the additive groups $\mathfrak{P}^i/\mathfrak{P}^{i+1}$; [174, Chapter IV, Section 2]). So when $\#I_{\mathfrak{P}}$ is prime to p, θ is injective and $I_{\mathfrak{P}}$, a subgroup of the cyclic group $\kappa(\mathfrak{P})^\times$, is cyclic. For F as stated, $\varpi' = F^{-1}(\varpi)$ is a uniformiser ($F \in D_{\mathfrak{P}}$ preserves $\mathfrak{P}$ and its powers), and $F\tau F^{-1}(\varpi)/\varpi = F(\tau(\varpi'))/F(\varpi') = F(\tau(\varpi')/\varpi')$. Reducing modulo $\mathfrak{P}$: the unit $\tau(\varpi')/\varpi'$ reduces to $\theta(\tau)$ (computed with the uniformiser ϖ', which is allowed), and F acts on $\kappa(\mathfrak{P})$ as $x \mapsto x^{N\mathfrak{p}}$, so $\theta(F\tau F^{-1}) = \theta(\tau)^{N\mathfrak{p}} = \theta(\tau^{N\mathfrak{p}})$. Injectivity of θ gives $F\tau F^{-1} = \tau^{N\mathfrak{p}}$. The profinite form, $\mathrm{Frob}\ t\ \mathrm{Frob}^{-1} = t^q$ on the tame inertia quotient of $G_{\mathbb{Q}_q}$, is proved in Chapter 7. □

Corollary 6.32 (Frobenius on a tame image of inertia)**.** *Let q be a prime, $\ell \neq q$ an odd prime, and $\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(\mathbb{Z}_\ell)$ continuous with $\rho(I_q)$ finite of order prime to q (for $\rho = \rho_{E,\ell}$ at a prime $q \geq 5$ of additive potentially good reduction the order is 2, 3, 4 or 6, by Kraus's theorem, Chapters 10 and 11). Then $\rho(I_q)$ is cyclic, and for every Frobenius $F \in D_q$ (Proposition 6.30) and every $\tau \in I_q$,*

$$\rho(F)\rho(\tau)\rho(F)^{-1} = \rho(\tau)^q.$$

In particular, if $\rho(I_q)$ is generated by σ of order 3 (or by $-\sigma$, of order 6), then $\rho(F)$ commutes with σ if $q \equiv 1 \pmod 3$ and conjugates it to σ^{-1} if $q \equiv 2 \pmod 3$; if $\rho(I_q)$ is generated by τ of order 4, $\rho(F)$ commutes with τ if $q \equiv 1 \pmod 4$ and conjugates it to τ^{-1} if $q \equiv 3 \pmod 4$. None of this depends on the choice of F.

Proof. The kernel $1 + \ell\,\mathrm{M}_2(\mathbb{Z}_\ell)$ of reduction modulo ℓ contains no nontrivial element of finite order when ℓ is odd (Chapters 1 and 4). For the reader's convenience, the argument: write $g \neq 1$ as $g = 1 + \ell^k x$ with $k \geq 1$ and $x \not\equiv 0 \pmod \ell$. For m prime to ℓ, $g^m \equiv 1 + m\ell^k x \not\equiv 1 \pmod{\ell^{k+1}}$. For $m = \ell$, $g^\ell = 1 + \ell^{k+1}x + \binom{\ell}{2}\ell^{2k}x^2 + \sum_{j\geq 3}\binom{\ell}{j}\ell^{jk}x^j$, where $\ell \mid \binom{\ell}{2}$ (ℓ odd) and $jk \geq k+2$ for $j \geq 3$; so $g^\ell = 1 + \ell^{k+1}x'$ with $x' \equiv x \not\equiv 0 \pmod \ell$, again of the same shape. By induction $g^{\ell^a} = 1 + \ell^{k+a}x_a$ with $x_a \not\equiv 0$, and then $g^{\ell^a m'} \neq 1$ for m' prime to ℓ; so g has infinite order. (For $\ell = 2$ the step $m = \ell$ fails at $k = 1$: $-1 \in 1 + 2\,\mathrm{M}_2(\mathbb{Z}_2)$.) Hence reduction $\rho \mapsto \bar\rho$ is injective on the finite group $\rho(I_q)$. Let L be the field cut out by $\bar\rho$, a finite Galois extension of $\mathbb{Q}$ with $\bar\rho$: $\mathrm{Gal}(L/\mathbb{Q}) \simeq \bar\rho(G_{\mathbb{Q}})$, and $\mathfrak{P} = \bar{\mathfrak{P}} \cap \mathcal{O}_L$. By Proposition 6.30(ii), $I_{\mathfrak{P}}$ is the image of I_q, so $\bar\rho(I_{\mathfrak{P}}) = \bar\rho(I_q) \simeq \rho(I_q)$ has order prime to q, and $F|_L \in D_{\mathfrak{P}}$ induces $x \mapsto x^q$ on $\kappa(\mathfrak{P})$.

Proposition 6.31 gives that $I_{\mathfrak{P}}$ is cyclic and $F|_L\,\tau|_L\,F|_L^{-1} = (\tau|_L)^q$, that is, $\bar\rho(F\tau F^{-1}) = \bar\rho(\tau^q)$. Both $F\tau F^{-1}$ and τ^q lie in I_q, which is normal in D_q; so $\rho(F\tau F^{-1})$ and $\rho(\tau)^q$ lie in $\rho(I_q)$ and have the same reduction, hence are equal. The special cases: $\sigma^q = \sigma$ or $\sigma^2 = \sigma^{-1}$ according to $q \bmod 3$ ($q \neq 3$ since $3 \mid \#\rho(I_q)$ is prime to q); $(-\sigma)^q = -\sigma^q$ for q odd, and for $q = 2$ the order 6 is not prime to q; $\tau^q = \tau$ or $\tau^3 = \tau^{-1}$ according to $q \bmod 4$. Two Frobenius elements differ by an element of I_q, whose image commutes with the cyclic group $\rho(I_q)$. □

In the paper 6.33. Lemma lem:IV: "The arithmetic Frobenius acts on the tame quotient of I_q by $x \mapsto x^q$, so $\rho(\mathrm{Frob}_q)\sigma\rho(\mathrm{Frob}_q)^{-1} = \sigma^q = \sigma^{\chi_{-3}(q)}$" (proof of Lemma lem:IV) is Corollary 6.32, at every prime $q \neq 3$ at which the image of inertia has order 3, including $q = 2$ (the order 3 is prime to 2); $\sigma^{\chi_{-3}(q)} = \sigma^q$ because $\chi_{-3}(q) = 1$ iff $q \equiv 1 \pmod 3$ (Proposition 6.35). Lemma lem:euler: "Frobenius centralises σ if $q \equiv 1 \pmod 3$ and inverts it if $q \equiv 2$, for either choice of Frobenius" is the same corollary, and the types III, III* use its order-4 case. The action on the invariant line of the adjoint is Proposition 6.45.

The general theory is now in place. The next section applies it to the quadratic fields, where everything can be computed by hand, and then passes from $\mathbb{Z}[\zeta_3]$ and $\mathbb{Z}[i]$ to their ℓ-adic versions, the rings that the image of inertia generates in the paper's lemmas on additive reduction.

6.4 Quadratic fields, $\mathbb{Z}[i]$, $\mathbb{Z}[\zeta_3]$ and the rings $\mathbb{Z}_\ell[\zeta_3]$

Quadratic fields carry all the characters of the paper: χ_{-3} and χ_{-4} in the table of Section 1 and in Lemma lem:euler, χ_{q^*} in the twists of Section 1.4 and Lemma lem:twist, χ_S in Theorems thm:twist and thm:quant, and $\mathbb{Q}(\sqrt{\ell^*})$ in the hypothesis of Theorem thm:main. This section proves the splitting law (Theorem 6.34), identifies the character of a quadratic field with a Kronecker symbol (Proposition 6.35), and then studies the two rings $\mathbb{Z}[i]$, $\mathbb{Z}[\zeta_3]$ and their ℓ-adic versions, which carry the algebra of Lemma lem:IV ($\mathbb{Z}_3[\zeta_3]$ a discrete valuation ring with uniformiser $\pi = 1-\zeta_3$, T_3E free of rank one over it, $E[3] \simeq \mathbb{Z}_3[\zeta_3]/(\pi^2)$) and of Lemma lem:euler (the line spanned by $\sqrt{-3} = 2\sigma + 1$ and the sign $\chi_{-3}(q)$). The Kronecker symbol $(\frac{D}{p})$ is that of Chapter 2: the Legendre symbol for odd p, and for $p = 2$ it is 0 if $2 \mid D$, 1 if $D \equiv \pm 1 \pmod 8$ and -1 if $D \equiv \pm 3 \pmod 8$.

Theorem 6.34 (splitting in quadratic fields)**.** *Let $K = \mathbb{Q}(\sqrt{d})$, $d \neq 0, 1$ squarefree, of discriminant D, and p a prime. Then p ramifies in K iff $(\frac{D}{p}) = 0$ (iff $p \mid D$), splits iff $(\frac{D}{p}) = 1$, and is inert iff $(\frac{D}{p}) = -1$. Explicitly: for odd $p \mid D$, $p\mathcal{O}_K = (p, \sqrt{d})^2$; for odd $p \nmid D$ with $a^2 \equiv d \pmod p$, $p\mathcal{O}_K = (p, \sqrt{d} - a)(p, \sqrt{d} + a)$ with distinct factors; for $p = 2$: if $d \equiv 3 \pmod 4$, $(2) = (2, 1 + \sqrt{d})^2$; if $d \equiv 2 \pmod 4$, $(2) = (2, \sqrt{d})^2$; if $d \equiv 1 \pmod 8$, $(2) = (2, \frac{1+\sqrt{d}}{2})(2, \frac{1-\sqrt{d}}{2})$; if $d \equiv 5 \pmod 8$, 2 is inert.*

Proof. Apply Theorem 6.20. If p is odd, take $\theta = \sqrt{d}$, $g = X^2 - d$: the index $[\mathcal{O}_K : \mathbb{Z}[\sqrt{d}]]$ is 1 or 2, prime to p. If $p \mid d$, $\bar g = X^2$ and $p = (p, \sqrt{d})^2$; if d is a nonzero square a^2 modulo p, $\bar g = (X - a)(X + a)$ with $a \not\equiv -a$; otherwise $\bar g$ is irreducible. For odd p, $p \mid D$ iff $p \mid d$, and $(\frac{D}{p}) = (\frac{d}{p})$ since $D/d \in \{1, 4\}$. If $p = 2$ and $d \equiv 2, 3 \pmod 4$, take $\theta = \sqrt{d}$ (index 1): $X^2 - d \equiv X^2$ or $(X + 1)^2 \pmod 2$, and $2 \mid D = 4d$. If $d \equiv 1 \pmod 4$ take $\theta_d = \frac{1+\sqrt{d}}{2}$, $g = X^2 - X + \frac{1-d}{4}$ (index 1): modulo 2, $g \equiv X(X + 1)$ if $\frac{1-d}{4}$ is even, that is $d \equiv 1 \pmod 8$, and $g \equiv X^2 + X + 1$, irreducible, if $d \equiv 5 \pmod 8$; here $D = d$ is odd and $(\frac{D}{2}) = 1$, resp. -1. The primes above 2 for $d \equiv 1 \pmod 8$ are $(2, \theta_d)$ and $(2, \theta_d - 1) = (2, \frac{1-\sqrt{d}}{2})$, as $\theta_d - 1 = -\frac{1-\sqrt{d}}{2}$. □

Proposition 6.35 (the character of a quadratic field)**.** *Let $K=\mathbb{Q}(\sqrt{d})$ have discriminant D and let $\chi_D\colon G_{\mathbb{Q}}\to\{\pm1\}$ be its character, $\sigma(\sqrt{d})=\chi_D(\sigma)\sqrt{d}$ (Chapter 5).*

(i) For every prime $p\nmid D$, $\chi_D(\mathrm{Frob}_p)=\left(\frac{D}{p}\right)$, the value at p of the primitive real Dirichlet character $n\mapsto\left(\frac{D}{n}\right)$ of conductor $|D|$ (Chapter 2).

(ii) χ_D is unramified exactly at the primes $p\nmid D$; for $p\mid D$, $\chi_D(I_p)=\{\pm1\}$.

(iii) In particular: $\chi_{-4}(\mathrm{Frob}_p)=(-1)^{(p-1)/2}$ for odd p (conductor 4); $\chi_{-3}(\mathrm{Frob}_p)=\left(\frac{p}{3}\right)$, which is 1 iff $p\equiv1 \pmod 3$, for $p\neq3$, including $\chi_{-3}(\mathrm{Frob}_2)=-1$ (conductor 3); for an odd prime q, $\chi_{q^*}(\mathrm{Frob}_p)=\left(\frac{q^*}{p}\right)=\left(\frac{p}{q}\right)$ for every prime $p\neq q$, including $p=2$ (conductor q); χ_8 and χ_{-8}, the characters of $\mathbb{Q}(\sqrt{2})$ and $\mathbb{Q}(\sqrt{-2})$, have conductor 8.

Proof. (i) p is unramified (Theorem 6.22, $d_K=D$), and $\mathrm{Frob}_p\in\mathrm{Gal}(K/\mathbb{Q})$ is trivial iff $D_{\mathfrak{P}}=1$ iff p splits (Proposition 6.27(iii)) iff $\left(\frac{D}{p}\right)=1$ (Theorem 6.34); since both sides are ±1 they agree. That $n\mapsto\left(\frac{D}{n}\right)$ is a primitive Dirichlet character of conductor $|D|$ for a fundamental discriminant D is proved in Chapter 2. (ii) For $p\mid D$, p ramifies, the inertia group in $\mathrm{Gal}(K/\mathbb{Q})$ has order $e=2$, and $\chi_D(I_p)$ is its image (Proposition 6.30(ii)). (iii) is (i) for $D=-4,-3,q^*,\pm8$, together with $\left(\frac{-4}{p}\right)=\left(\frac{-1}{p}\right)=(-1)^{(p-1)/2}$, $\left(\frac{-3}{p}\right)=\left(\frac{p}{3}\right)$ and $\left(\frac{q^*}{p}\right)=\left(\frac{p}{q}\right)$ (quadratic reciprocity with its supplements, Chapter 2, or Corollary 6.52); at $p=2$, $\left(\frac{q^*}{2}\right)=1$ iff $q^*\equiv1 \pmod 8$ iff $q\equiv\pm1 \pmod 8$ iff $\left(\frac{2}{q}\right)=1$. All these congruence conditions were also checked numerically for $p<3000$. □

Proposition 6.36 (quadratic fields unramified outside a set of primes)**.** *(i) For an odd prime q, $\mathbb{Q}(\sqrt{q^*})$, $q^*=(-1)^{(q-1)/2}q$, is the unique quadratic field ramified only at q; its discriminant is q^*. (ii) Every fundamental discriminant is uniquely a product $D=D_0\prod_{q\in T}q^*$ with T a finite set of odd primes and $D_0\in\{1,-4,8,-8\}$ (the* prime discriminants*). A quadratic field is unramified outside a finite set S of primes iff its discriminant has this form with $T\subseteq S$ and $D_0=1$ unless $2\in S$. (iii) For a finite set S of odd primes, $\chi_S:=\prod_{q\in S}\chi_{q^*}$ is the character of $\mathbb{Q}(\sqrt{\prod_{q\in S}q^*})$, of discriminant $\prod_{q\in S}q^*$ and conductor $\prod_{q\in S}q$; it is ramified exactly at the primes of S. (iv) Hence twisting a representation of $G_{\mathbb{Q}}$ by χ_{q^*} or by χ_S does not change it on I_p for $p\notin S$.*

Proof. (i) $q^*\equiv1 \pmod 4$ and is squarefree, so it is a fundamental discriminant, and $\mathbb{Q}(\sqrt{q^*})$ is ramified exactly at q (Theorem 6.22). Conversely, a quadratic field ramified only at q has odd discriminant D divisible only by q, so $D=\pm q$; an odd fundamental discriminant is $\equiv1 \pmod 4$, which fixes the sign: $D=q^*$. (ii) If D is odd, it is squarefree and $\equiv1 \pmod 4$; writing $D=\pm\prod_{q\mid D}q$, the product $\prod_{q\mid D}q^*$ has the same absolute value and is $\equiv1 \pmod 4$, so equals D. If $D=4m$ with $m\equiv3 \pmod 4$, then $-m\equiv1 \pmod 4$ is an odd fundamental discriminant (or 1) and $D=-4\cdot(-m)$; if $m\equiv2 \pmod 4$, $m=2m'$ with m' odd, and $D=8m'=\pm8\cdot(\pm m')$ with the sign chosen so that $\pm m'\equiv1 \pmod 4$. Uniqueness: the odd part determines T, the sign and the 2-part then determine D_0. The second statement follows from Theorem 6.22. (iii) $\prod_{q\in S}\chi_{q^*}(\sigma)$ is the sign by which σ multiplies $\prod_{q\in S}\sqrt{q^*}$, a square root of $\prod q^*$; the product is a fundamental discriminant by (ii), whose conductor is its absolute value. (iv) χ_S is trivial on I_p for $p\notin S$ by (iii) and Proposition 6.35(ii). □

Example 6.37 (splitting tables)**.** By Theorem 6.34 and quadratic reciprocity:

field	D	ramified	p splits iff
$\mathbb{Q}(i)$	-4	2	$p \equiv 1 \pmod 4$
$\mathbb{Q}(\sqrt{-3}) = \mathbb{Q}(\zeta_3)$	-3	3	$p \equiv 1 \pmod 3$ (2 is inert)
$\mathbb{Q}(\sqrt{-7})$	-7	7	$p \equiv 1, 2, 4 \pmod 7$ (2 splits, $-7 \equiv 1 \pmod 8$)
$\mathbb{Q}(\sqrt{-11})$	-11	11	p a square modulo 11 (2, 7 inert; 3, 5 split)
$\mathbb{Q}(\sqrt{5})$	5	5	$p \equiv \pm 1 \pmod 5$
$\mathbb{Q}(\sqrt{-5})$	-20	2, 5	$p \equiv 1, 3, 7, 9 \pmod{20}$ (3 and 7 split)

The paper's twists by these fields: 121a1 and its twist by χ_{-11} ($\mathbb{Q}(\sqrt{-11}) = \mathbb{Q}(\sqrt{11^*})$), 539c1 and 980i1 twisted by χ_{-7} ($\mathbb{Q}(\sqrt{-7}) = \mathbb{Q}(\sqrt{7^*})$), in the Example after the proof of Theorem thm:qual (Example ex:qual).

Proposition 6.38 (Gaussian and Eisenstein primes)**.** *(i) $\mathbb{Z}[i]$ and $\mathbb{Z}[\zeta_3]$ are Euclidean for the norms $a^2 + b^2$ and $a^2 - ab + b^2$ (Chapter 2), hence principal ideal domains; their unit groups are μ_4 and μ_6 (Theorem 6.9). (ii) Up to units, the primes of $\mathbb{Z}[i]$ are: $1 + i$, with $2 = -i(1 + i)^2$; for each $p \equiv 1 \pmod 4$, the two non-associate factors $a \pm bi$ of $p = a^2 + b^2$; for each $p \equiv 3 \pmod 4$, p itself. For example $5 = (2 + i)(2 - i)$, $13 = (3 + 2i)(3 - 2i)$. (iii) Up to units, the primes of $\mathbb{Z}[\zeta_3]$ are: $\pi = 1 - \zeta_3$ (Proposition 6.39); for each $p \equiv 1 \pmod 3$, the two non-associate factors $a + b\zeta_3$, $a + b\zeta_3^2$ of $p = a^2 - ab + b^2$; for each $p \equiv 2 \pmod 3$, p itself. For example $7 = (3 + \zeta_3)(3 + \zeta_3^2)$, $13 = (4 + \zeta_3)(4 + \zeta_3^2)$. (iv) A prime p is a sum of two squares iff $p = 2$ or $p \equiv 1 \pmod 4$ (Fermat); $p = a^2 - ab + b^2$ for integers a, b iff $p = 3$ or $p \equiv 1 \pmod 3$, and then $p = x^2 + 3y^2$ for some integers x, y.*

Proof. (ii) Every prime ϖ of $\mathbb{Z}[i]$ lies above a unique rational p (Theorem 6.11), and the primes above p are given by Example 6.37: $p = 2$ is ramified, $p \equiv 1 \pmod 4$ split, $p \equiv 3 \pmod 4$ inert. In the split case $p\mathbb{Z}[i] = \mathfrak{P}\bar{\mathfrak{P}}$ with $\mathfrak{P} = (a + bi)$ principal of norm p, so $a^2 + b^2 = p$, and $\bar{\mathfrak{P}} = (a - bi) \neq \mathfrak{P}$. In the inert case (p) is prime. (iii) The same with Example 6.21(b) and $N(a + b\zeta_3) = a^2 - ab + b^2$, $\overline{a + b\zeta_3} = a + b\zeta_3^2$. (iv) p is a norm from $\mathbb{Z}[i]$ (resp. $\mathbb{Z}[\zeta_3]$) iff some prime above p has norm p, iff p is ramified or split. If $p = a^2 - ab + b^2$, then p is odd (it is 3 or $\equiv 1 \pmod 3$), so not both a, b are even, and one of a, b, $a - b$ is even; by the symmetries $(a, b) \mapsto (b, a)$ and $(a, b) \mapsto (a - b, -b)$, which preserve the form, we may assume $b = 2y$ even, and then $p = (a - y)^2 + 3y^2$. The small cases were also checked by computer for $p < 300$. □

Proposition 6.39 (the prime above 3)**.** *In $\mathbb{Z}[\zeta_3]$ put $\pi = 1 - \zeta_3$ and $\sqrt{-3} := 1 + 2\zeta_3$.*

(i) $(\sqrt{-3})^2 = -3$, $\sqrt{-3} = \zeta_3 - \zeta_3^2 = \zeta_3\pi$, $\pi^2 = -3\zeta_3$ and $3 = -\zeta_3^2\pi^2$. So π and $\sqrt{-3}$ are associates, $N(\pi) = 3$, $3\mathbb{Z}[\zeta_3] = (\pi)^2$ (3 is totally ramified), and $\pi^2 = -3$ up to the unit ζ_3.

(ii) $\mathbb{Z}[\zeta_3]/(\pi) = \mathbb{F}_3$, and $\zeta_3 \equiv 1 \pmod \pi$.

(iii) $\mathbb{Z}[\zeta_3]/(3) = \mathbb{Z}[\zeta_3]/(\pi^2)$ is a local ring with nine elements, with $\mathbb{F}_3$-basis $1, \pi$; multiplication by $\zeta_3 = 1 - \pi$ has the matrix $\left(\begin{smallmatrix} 1 & 0 \\ -1 & 1 \end{smallmatrix}\right)$ in this basis. It is a nontrivial unipotent map, and its fixed points form the line $\pi\mathbb{Z}[\zeta_3]/(\pi^2)$.

(iv) The analogue at 2 in $\mathbb{Z}[i]$: $(2) = (1 + i)^2$, $\mathbb{Z}[i]/(2) \simeq \mathbb{F}_2[x]/(x^2)$ with $x = 1 + i$, and multiplication by $i = 1 + x$ is a nontrivial unipotent map.

Proof. All identities follow from $\zeta_3^2 = -1 - \zeta_3$: $(1 + 2\zeta_3)^2 = 1 + 4\zeta_3 + 4\zeta_3^2 = -3$; $\zeta_3 - \zeta_3^2 = 1 + 2\zeta_3$; $\zeta_3\pi = \zeta_3 - \zeta_3^2$; $\pi^2 = 1 - 2\zeta_3 + \zeta_3^2 = -3\zeta_3$; $-\zeta_3^2\pi^2 = 3\zeta_3^3 = 3$. $N(\pi) = 1 + 1 + 1 = 3$. (ii) $\mathbb{Z}[\zeta_3]/(\pi)$ has $N(\pi) = 3$ elements, and $\zeta_3 = 1 - \pi$. (iii) $(3) = (\pi^2)$ by (i); the quotient has 9 elements, its

ideals are 0, $(\pi)/(\pi^2)$ and the whole ring (Proposition 6.15(i)), and $1, \pi$ is a basis since $\pi \notin (\pi^2)$. $\zeta_3 \cdot 1 = 1 - \pi$ and $\zeta_3 \pi = \pi - \pi^2 \equiv \pi$, giving the matrix (columns are images). The fixed points of $x \mapsto \zeta_3 x$ are the x with $\pi x \equiv 0$, that is $x \in (\pi)$. (iv) $(1+i)^2 = 2i$, so $(2) = (1+i)^2$; $\mathbb{Z}[i]/(2)$ has basis $1, x$ with $x^2 = 2i \equiv 0$, and $i \cdot 1 = 1 + x$, $i \cdot x = x + x^2 = x$. □

Lemma 6.40 (quadratic algebras over $\mathbb{Z}_\ell$)**.** *Let ℓ be a prime, $g \in \mathbb{Z}_\ell[X]$ monic of degree 2, $R = \mathbb{Z}_\ell[X]/(g)$ (free over $\mathbb{Z}_\ell$ with basis $1, x$, x the class of X) and $\bar{g} = g \bmod \ell$.*

(i) If $\bar{g}$ is irreducible over $\mathbb{F}_\ell$, R is a discrete valuation ring with uniformiser ℓ and residue field $\mathbb{F}_{\ell^2}$.

(ii) If $g(X + c)$ is an Eisenstein polynomial at ℓ for some $c \in \mathbb{Z}_\ell$, R is a discrete valuation ring with uniformiser $x - c$ and residue field $\mathbb{F}_\ell$, and $\ell R = (x - c)^2 R$.

(iii) If $\bar{g} = (X - \bar{a})(X - \bar{b})$ with $\bar{a} \neq \bar{b}$, then g has roots $a, b \in \mathbb{Z}_\ell$ lifting $\bar{a}, \bar{b}$, and $R \simeq \mathbb{Z}_\ell \times \mathbb{Z}_\ell$, $x \mapsto (a, b)$.

In each case R is a principal ideal ring. If T is an R-module which is free of rank 2 over $\mathbb{Z}_\ell$ and satisfies $T \otimes \mathbb{Q}_\ell \simeq R \otimes \mathbb{Q}_\ell$ as $R \otimes \mathbb{Q}_\ell$-modules (automatic in cases (i) and (ii)), then T is free of rank one over R.

Proof. R is Noetherian (finite over $\mathbb{Z}_\ell$) and ℓ-adically complete, so an element $1 - \ell z$ is a unit ($\sum_k (\ell z)^k$ converges). (i) $R/\ell R = \mathbb{F}_\ell[X]/(\bar{g}) = \mathbb{F}_{\ell^2}$ is a field, so ℓR is maximal. If $y \notin \ell R$, $\bar{y}$ is invertible in $R/\ell R$: $yy' = 1 - \ell z$, and y is a unit. So R is local with maximal ideal ℓR. Every nonzero y is $\ell^k y_0$ with $y_0 \notin \ell R$ (as $\bigcap_k \ell^k R = 0$, R being free over $\mathbb{Z}_\ell$), so a product of nonzero elements is $\ell^{k+k'}$ times a unit, nonzero: R is a domain. A Noetherian local domain, not a field, with principal maximal ideal is a discrete valuation ring (Chapter 3). (ii) Write $y = x - c$, so $R = \mathbb{Z}_\ell[Y]/(Y^2 + uY + v)$ with $u = \ell u'$, $u' \in \mathbb{Z}_\ell$, and $v = \ell w_0$, $w_0 \in \mathbb{Z}_\ell^\times$. Then $R/(y) = \mathbb{Z}_\ell/(v) = \mathbb{F}_\ell$, so (y) is maximal. If $z = s + ty$ ($s, t \in \mathbb{Z}_\ell$) is not in (y), then $\ell \nmid s$, and the determinant of multiplication by z in the basis $1, y$ is $s^2 - stu + t^2 v \equiv s^2 \not\equiv 0 \pmod{\ell}$; so z is a unit (Cayley-Hamilton, as in Proposition 6.5(ii)), and R is local with maximal ideal (y). Next $y^2 = -\ell(u'y + w_0)$ with $u'y + w_0 \notin (y)$ a unit, so $\ell R = y^2 R$. Hence $\bigcap_k y^k R = \bigcap_k \ell^k R = 0$, every nonzero z is $y^k w$ with w a unit (k the largest exponent with $z \in y^k R$), and $y^k \neq 0$ for all k; so a product of nonzero elements is nonzero, R is a domain, and it is a discrete valuation ring with uniformiser y (Chapter 3). (iii) $R/\ell R \simeq \mathbb{F}_\ell[X]/(X - \bar{a}) \times \mathbb{F}_\ell[X]/(X - \bar{b}) = \mathbb{F}_\ell \times \mathbb{F}_\ell$ by the Chinese remainder theorem. Its idempotent $(1, 0)$ lifts to an idempotent $e \in R$ (Chapter 3, idempotent lifting over the complete ring $\mathbb{Z}_\ell$). Then $R = Re \times R(1 - e)$, each factor is a direct summand of $R \simeq \mathbb{Z}_\ell^2$, hence free over $\mathbb{Z}_\ell$, and nonzero modulo ℓ, hence of rank 1; as $Re/\ell Re \simeq \mathbb{F}_\ell$ is spanned by $\bar{e}$, Nakayama gives $Re = \mathbb{Z}_\ell e$, and similarly $R(1-e) = \mathbb{Z}_\ell(1-e)$. So $R \simeq \mathbb{Z}_\ell \times \mathbb{Z}_\ell$ as rings, and the image of x is a pair (a, b) of roots of g in $\mathbb{Z}_\ell$ reducing to $\bar{a}, \bar{b}$. Modules: a discrete valuation ring and $\mathbb{Z}_\ell \times \mathbb{Z}_\ell$ are principal ideal rings. Let T be as stated. If R is a discrete valuation ring, T is finitely generated and torsion-free over R (if $zt = 0$ with $z \neq 0$, put $z' = \mathrm{Tr}(z) - z$, with Tr and N the trace and determinant of multiplication by z on R; by Cayley-Hamilton $zz' = N(z)$, which is nonzero as R is a domain, so $N(z)t = z'zt = 0$ and $t = 0$), hence free (Chapter 3), of rank $\mathrm{rank}_{\mathbb{Z}_\ell} T / \mathrm{rank}_{\mathbb{Z}_\ell} R = 1$; in this case $R \otimes \mathbb{Q}_\ell$ is a field and the hypothesis on $T \otimes \mathbb{Q}_\ell$ holds automatically. If $R = \mathbb{Z}_\ell e \times \mathbb{Z}_\ell(1 - e)$, then $T = eT \oplus (1 - e)T$, each summand free over $\mathbb{Z}_\ell$, of ranks $\dim(e(T \otimes \mathbb{Q}_\ell)) = 1$ and 1 by the hypothesis; a generator t_1 of eT and t_2 of $(1 - e)T$ give $T = R(t_1 + t_2)$. □

Theorem 6.41 ($\mathbb{Z}_3[\zeta_3]$)**.** *Let $\mathbb{Z}_3[\zeta_3] := \mathbb{Z}_3[X]/(X^2 + X + 1)$, ζ_3 the class of X, $\pi = 1 - \zeta_3$. Then:*

(i) $\mathbb{Z}_3[\zeta_3]$ *is an integral domain, free over* $\mathbb{Z}_3$ *with basis* $1, \zeta_3$ *(or* $1, \pi$*), and* $\mathbb{Z}_3[\zeta_3] \simeq \mathbb{Z}_3 \otimes_{\mathbb{Z}} \mathbb{Z}[\zeta_3]$*;*

(ii) it is a discrete valuation ring with maximal ideal (π)*, uniformiser* π *and residue field* $\mathbb{F}_3$*; every nonzero element is* $u\pi^k$ *with* u *a unit and* $k \geq 0$*;*

(iii) $\pi^2 = -3\zeta_3$*, so* $3\mathbb{Z}_3[\zeta_3] = \pi^2\mathbb{Z}_3[\zeta_3]$ *and* $v_\pi(3) = 2$*;*

(iv) (stated; Chapter 7) it is the π*-adic completion of* $\mathbb{Z}[\zeta_3]$ *and the ring of integers of* $\mathbb{Q}_3(\zeta_3) = \mathbb{Q}_3(\sqrt{-3})$*, a totally ramified quadratic extension of* $\mathbb{Q}_3$*.*

Proof. With $g = X^2+X+1$ and $c = 1$, $g(X+1) = X^2+3X+3$ is Eisenstein at 3; Lemma 6.40(ii) gives (i) except the last isomorphism, (ii) with uniformiser $\zeta_3 - 1 = -\pi$, and $3\mathbb{Z}_3[\zeta_3] = \pi^2\mathbb{Z}_3[\zeta_3]$; the identity $\pi^2 = -3\zeta_3$ is Proposition 6.39(i). The isomorphism $\mathbb{Z}_3 \otimes_{\mathbb{Z}} \mathbb{Z}[\zeta_3] = \mathbb{Z}_3 \otimes_{\mathbb{Z}} \mathbb{Z}[X]/(X^2 + X + 1) \simeq \mathbb{Z}_3[X]/(X^2 + X + 1)$ is right exactness of the tensor product. A direct check of locality: if $a + b\zeta_3 \notin (\pi)$, i.e. $3 \nmid a + b$, then $N(a + b\zeta_3) = a^2 - ab + b^2 \equiv (a + b)^2 \not\equiv 0 \pmod 3$ and $(a + b\zeta_3)^{-1} = (a + b\zeta_3^2)/(a^2 - ab + b^2)$. (iv) We do not prove this here; see Chapter 7 and [174, Chapter I, Section 6]. □

Corollary 6.42 (the lattice of Lemma lem:IV)**.** *Let* T *be a free* $\mathbb{Z}_3$*-module of rank* 2 *and* $\sigma \in \mathrm{Aut}_{\mathbb{Z}_3}(T)$ *with* $\sigma^2 + \sigma + 1 = 0$ *(for* $\sigma \in \mathrm{SL}_2(\mathbb{Z}_3)$ *of order* 3 *this holds, its eigenvalues being the primitive cube roots of unity, Chapter 4). Make* T *a* $\mathbb{Z}_3[\zeta_3]$*-module with* ζ_3 *acting as* σ*. Then:*

(i) T *is free of rank one over* $\mathbb{Z}_3[\zeta_3]$*, and* $\mathbb{Z}_3[\sigma] \simeq \mathbb{Z}_3[X]/(X^2 + X + 1)$*;*

(ii) $T/3T \simeq \mathbb{Z}_3[\zeta_3]/(\pi^2)$*, and* σ *acts on* $T/3T$ *as the nontrivial unipotent map of Proposition 6.39(iii), with fixed line* $\pi T/3T$*;*

(iii) for every $k \geq 1$ *the* σ*-fixed vectors of* $T/\pi^k T$ *form the line* $\pi^{k-1}T/\pi^k T$ *over* $\mathbb{F}_3$*, and* $T^\sigma = 0$*.*

Proof. (i) σ is not a scalar: a scalar $s \in \mathbb{Z}_3$ with $s^2 + s + 1 = 0$ does not exist (Theorem 6.41(i); directly, $s^2 + s + 1 \equiv (s - 1)^2 \pmod 3$ forces $s = 1 + 3t$, and then $s^2 + s + 1 = 3 + 9t + 9t^2 \equiv 3 \pmod 9$ is not 0). So the polynomials over $\mathbb{Z}_3$ killing σ are exactly the multiples of $X^2 + X + 1$ (division by the monic $X^2 + X + 1$ leaves a remainder $a + bX$ with $a + b\sigma = 0$, and $b \neq 0$ would make $\sigma = -a/b$ a scalar in $\mathbb{Q}_3$ satisfying $s^2 + s + 1 = 0$, hence in $\mathbb{Z}_3$ since $\mathbb{Z}_3$ is integrally closed, which was just excluded), and $\mathbb{Z}_3[\sigma] \simeq \mathbb{Z}_3[X]/(X^2 + X + 1)$. T is torsion-free over the domain $\mathbb{Z}_3[\zeta_3]$ by the norm argument of Lemma 6.40, hence free, of rank $2/2 = 1$. (ii) $T \simeq \mathbb{Z}_3[\zeta_3]$ gives $T/3T \simeq \mathbb{Z}_3[\zeta_3]/(3) = \mathbb{Z}_3[\zeta_3]/(\pi^2) \simeq \mathbb{Z}[\zeta_3]/(\pi^2)$, and Proposition 6.39(iii) applies. (iii) In $\mathbb{Z}_3[\zeta_3]/(\pi^k)$, $\zeta_3 x = x$ iff $\pi x \equiv 0 \pmod{\pi^k}$ iff $x \in (\pi^{k-1})$ (write $x = u\pi^j$ with u a unit, Theorem 6.41(ii)); and in T itself $\pi x = 0$ forces $x = 0$, as T is torsion-free over the domain $\mathbb{Z}_3[\zeta_3]$. □

A worked case: let $T = \mathbb{Z}_3^2$ and let $\sigma = \left(\begin{smallmatrix} 0 & -1 \\ 1 & -1 \end{smallmatrix}\right)$ be the companion matrix of $X^2 + X + 1$ ($\sigma e_1 = e_2$, $\sigma e_2 = -e_1 - e_2$). Then e_1 generates T over $\mathbb{Z}_3[\sigma]$, as $e_1, \sigma e_1 = e_2$ is a basis, and the isomorphism $\mathbb{Z}_3[\zeta_3] \to T$, $z \mapsto z \cdot e_1$, sends $1, \zeta_3$ to e_1, e_2. Modulo 3, $\sigma - 1 \equiv \left(\begin{smallmatrix} 2 & 2 \\ 1 & 1 \end{smallmatrix}\right)$ has rank one and $(\sigma - 1)^2 \equiv \left(\begin{smallmatrix} 6 & 6 \\ 3 & 3 \end{smallmatrix}\right) \equiv 0$, so σ is a nontrivial unipotent on $T/3T$; its fixed line is the kernel of $\left(\begin{smallmatrix} 2 & 2 \\ 1 & 1 \end{smallmatrix}\right)$, spanned by $e_1 - e_2 = (1 - \sigma)e_1 = \pi e_1$, which is the line $\pi T/3T$ of (ii).

Proposition 6.43 ($\mathbb{Z}_\ell[\zeta_3]$ and $\mathbb{Z}_\ell[i]$)**.** *For a prime* ℓ *put* $\mathbb{Z}_\ell[\zeta_3] := \mathbb{Z}_\ell[X]/(X^2+X+1) \simeq \mathbb{Z}_\ell \otimes_{\mathbb{Z}} \mathbb{Z}[\zeta_3]$ *and* $\mathbb{Z}_\ell[i] := \mathbb{Z}_\ell[X]/(X^2 + 1) \simeq \mathbb{Z}_\ell \otimes_{\mathbb{Z}} \mathbb{Z}[i]$*. These are defined as these quotient rings, not as subrings of an algebraic closure of* $\mathbb{Q}_\ell$*.*

(i) $\ell = 3$*:* $\mathbb{Z}_3[\zeta_3]$ *is the ramified discrete valuation ring of Theorem 6.41.*

(ii) $\ell \equiv 1 \pmod 3$*:* $X^2 + X + 1$ *has two distinct roots in* $\mathbb{Z}_\ell$*, and* $\mathbb{Z}_\ell[\zeta_3] \simeq \mathbb{Z}_\ell \times \mathbb{Z}_\ell$*, which is not a domain.*

(iii) $\ell \equiv 2 \pmod 3$*:* $\mathbb{Z}_\ell[\zeta_3]$ *is an unramified discrete valuation ring with uniformiser* ℓ *and residue field* $\mathbb{F}_{\ell^2}$*.*

(iv) Likewise $\mathbb{Z}_\ell[i] \simeq \mathbb{Z}_\ell \times \mathbb{Z}_\ell$ *for* $\ell \equiv 1 \pmod 4$*, an unramified discrete valuation ring with residue field* $\mathbb{F}_{\ell^2}$ *for* $\ell \equiv 3 \pmod 4$*, and a ramified discrete valuation ring with uniformiser* $1 + i$ *for* $\ell = 2$*.*

(v) In all cases $\mathbb{Q}_\ell[\zeta_3] := \mathbb{Z}_\ell[\zeta_3][1/\ell] = \mathbb{Q}_\ell \otimes_{\mathbb{Q}} \mathbb{Q}(\zeta_3)$ *carries the* $\mathbb{Q}_\ell$*-linear involution* $\zeta_3 \mapsto \zeta_3^2$ *(the nontrivial element of* $\mathrm{Gal}(\mathbb{Q}(\zeta_3)/\mathbb{Q})$*, extended by scalars), which negates* $\sqrt{-3} = 1+2\zeta_3$*; and* $\sqrt{-3}$ *is a unit of* $\mathbb{Z}_\ell[\zeta_3]$ *iff* $\ell \neq 3$*. The same holds for* $\mathbb{Q}_\ell[i]$ *with* $i \mapsto -i$*, and* $2i$ *is a unit of* $\mathbb{Z}_\ell[i]$ *iff* $\ell \neq 2$*.*

The trichotomy is the splitting of ℓ *in* $\mathbb{Q}(\zeta_3)$ *and in* $\mathbb{Q}(i)$ *(Example 6.37), and is the case* $K = \mathbb{Q}(\zeta_3)$*,* $\mathbb{Q}(i)$ *of Proposition 6.69.*

Proof. (i) is Theorem 6.41. For $\ell \neq 3$, $X^2 + X + 1$ is separable modulo ℓ (its discriminant is -3), and it has a root in $\mathbb{F}_\ell$ iff $\mathbb{F}_\ell^\times$ contains an element of order 3 iff $3 \mid \ell - 1$ (Chapter 2). So (ii) and (iii) are Lemma 6.40(iii) and (i) (for $\ell = 2$, $X^2 + X + 1$ is irreducible over $\mathbb{F}_2$, and $2 \equiv 2 \pmod 3$). (iv) The same with $X^2 + 1$, of discriminant -4: for odd ℓ it has a root modulo ℓ iff $4 \mid \ell - 1$; for $\ell = 2$, $(X + 1)^2 + 1 = X^2 + 2X + 2$ is Eisenstein. (v) The tensor product with $\mathbb{Q}_\ell$ of the automorphism $\zeta_3 \mapsto \zeta_3^2$ of $\mathbb{Z}[\zeta_3]$ preserves $\mathbb{Z}_\ell[\zeta_3]$ and sends $1 + 2\zeta_3$ to $1 + 2\zeta_3^2 = -(1 + 2\zeta_3)$. $(\sqrt{-3})^2 = -3$ is a unit iff $\ell \neq 3$, and then $\sqrt{-3}$ is a unit; for $\ell = 3$ it lies in the maximal ideal (π). Likewise $(2i)^2 = -4$. □

Proposition 6.44 (lattices with an automorphism of order 3, 4 or 6)**.** *Let* ℓ *be an odd prime,* T *a free* $\mathbb{Z}_\ell$*-module of rank* 2*,* $m \in \{3, 4, 6\}$*, and* $g \in \mathrm{Aut}_{\mathbb{Z}_\ell}(T)$ *with characteristic polynomial the cyclotomic polynomial* Φ_m *(*$X^2 + X + 1$*,* $X^2 + 1$*,* $X^2 - X + 1$*). This holds for every* $g \in \mathrm{SL}_2(\mathbb{Z}_\ell)$ *of order* m *(its eigenvalues are* ζ*,* ζ^{-1} *with* ζ *a primitive* m*-th root of unity). Then* $\mathbb{Z}_\ell[g] \simeq \mathbb{Z}_\ell[X]/(\Phi_m)$*, which is* $\mathbb{Z}_\ell[\zeta_3]$ *for* $m = 3, 6$ *(via* $X \mapsto \zeta_3$*, resp.* $X \mapsto -\zeta_3$*) and* $\mathbb{Z}_\ell[i]$ *for* $m = 4$*;* T *is free of rank one over* $\mathbb{Z}_\ell[g]$*; and the commutant of* g *in* $\mathrm{End}_{\mathbb{Z}_\ell}(T)$ *is* $\mathbb{Z}_\ell[g]$*. For* $\ell = 3$ *and* $m = 3$ *this is Corollary 6.42.*

Proof. g is not a scalar (its characteristic polynomial has distinct roots), so Φ_m is its minimal polynomial and $\mathbb{Z}_\ell[g] \simeq \mathbb{Z}_\ell[X]/(\Phi_m) =: R$; and $\Phi_6(X) = \Phi_3(-X)$. By Proposition 6.43, R is a discrete valuation ring or $\mathbb{Z}_\ell \times \mathbb{Z}_\ell$. Over $\mathbb{Q}_\ell$, $T \otimes \mathbb{Q}_\ell$ is a cyclic $\mathbb{Q}_\ell[g]$-module (a non-scalar endomorphism of a plane has a cyclic vector: if every nonzero vector were an eigenvector, two independent eigenvectors and their sum would have to share one eigenvalue and g would be a scalar; so some v is not an eigenvector, and v, gv is a basis), so $T \otimes \mathbb{Q}_\ell \simeq R \otimes \mathbb{Q}_\ell$ via $z \mapsto zv$, and Lemma 6.40 gives $T \simeq R$. Then the commutant of g is $\mathrm{End}_R(T) = \mathrm{End}_R(R) = R$, since an R-linear endomorphism of R is multiplication by the image of 1. (In the split case the idempotents are explicit: if $\zeta \in \mathbb{Z}_\ell$ is a root of Φ_m, the other root is ζ^{-1}, and $e = (g - \zeta^{-1})/(\zeta - \zeta^{-1})$ is 1 on the ζ-eigenline and 0 on the ζ^{-1}-eigenline. It lies in $\mathbb{Z}_\ell[g]$ because its denominator is a unit: $(\zeta - \zeta^{-1})^2 = (\zeta + \zeta^{-1})^2 - 4$ is $1 - 4 = -3$ for $m = 3, 6$ and $0 - 4 = -4$ for $m = 4$, units for ℓ odd, $\ell \neq 3$; and the split case requires $\ell \neq 3$.) □

Proposition 6.45 (the commutant and the invariant line of the adjoint)**.** *Let F be a field of characteristic 0, V a two-dimensional F-vector space, and $\sigma \in \mathrm{GL}(V)$ with characteristic polynomial X^2+X+1 (so $\sigma^3=1$, $\det\sigma=1$).*

(i) The commutant $\{x \in \mathrm{End}_F(V) : x\sigma = \sigma x\}$ is $F[\sigma] \simeq F[X]/(X^2+X+1) = F \otimes_{\mathbb{Q}} \mathbb{Q}(\zeta_3)$, of dimension 2; it is a field iff F contains no primitive cube root of unity (for $F=\mathbb{Q}_\ell$: iff $\ell \not\equiv 1 \pmod 3$). The same holds for $-\sigma$.

(ii) The trace-zero part of $F[\sigma]$ is the line $F\cdot(2\sigma+1)$, and $(2\sigma+1)^2 = -3$: it is the line spanned by a square root of -3.

(iii) If $A \in \mathrm{GL}(V)$ satisfies $A\sigma A^{-1} = \sigma^q$ for a prime $q \neq 3$, then conjugation by A preserves $F[\sigma]$ and acts on it as $\mathrm{id}_F \otimes \mathrm{Frob}_q$, where $\mathrm{Frob}_q \in \mathrm{Gal}(\mathbb{Q}(\zeta_3)/\mathbb{Q})$ is $\zeta_3 \mapsto \zeta_3^q$; hence it acts on the line $F(2\sigma+1)$ by $\chi_{-3}(\mathrm{Frob}_q) = \chi_{-3}(q)$, and so does conjugation by A^{-1}.

(iv) If $\tau \in \mathrm{GL}(V)$ has characteristic polynomial X^2+1, the commutant is $F[\tau] \simeq F \otimes_{\mathbb{Q}} \mathbb{Q}(i)$, its trace-zero part is $F\tau$, and $A\tau A^{-1} = \tau^q$ with q an odd prime gives the action of conjugation by $A^{\pm 1}$ on $F\tau$ by $\chi_{-4}(q)$.

(v) Integral form: if $F=\mathbb{Q}_\ell$, ℓ odd, and $T \subset V$ is a σ-stable $\mathbb{Z}_\ell$-lattice, the commutant of σ in $\mathrm{End}_{\mathbb{Z}_\ell}(T)$ is $\mathbb{Z}_\ell[\sigma] \simeq \mathbb{Z}_\ell \otimes_{\mathbb{Z}} \mathbb{Z}[\zeta_3]$, and T is free of rank one over it (Proposition 6.44); $\mathrm{End}_{\langle\sigma\rangle}(V) = \mathbb{Q}_\ell[\sigma] \simeq \mathbb{Q}_\ell \otimes_{\mathbb{Q}} \mathbb{Q}(\zeta_3)$. For $\ell \equiv 1 \pmod 3$ neither is a domain.

Proof. (i) σ is not a scalar, so V has a cyclic vector v ($v, \sigma v$ a basis); an x commuting with σ is determined by $x(v) = av + b\sigma v$, so $x = a + b\sigma$. $F[X]/(X^2+X+1)$ is a field iff X^2+X+1 has no root in F; for $\mathbb{Q}_\ell$ use Proposition 6.43. (ii) $\mathrm{tr}(a+b\sigma) = 2a-b$, which vanishes iff $a+b\sigma = \frac{b}{2}(2\sigma+1)$; and $(2\sigma+1)^2 = 4(\sigma^2+\sigma+1) - 3 = -3$. (iii) $AF[\sigma]A^{-1} = F[\sigma^q] = F[\sigma]$, and conjugation is an F-algebra automorphism sending $\sigma \mapsto \sigma^q$, which under $\sigma \leftrightarrow 1\otimes\zeta_3$ is $\mathrm{id}\otimes(\zeta_3 \mapsto \zeta_3^q)$. Explicitly $A(2\sigma+1)A^{-1} = 2\sigma^q + 1$, which is $2\sigma+1$ if $q \equiv 1 \pmod 3$ and $2\sigma^2+1 = -(2\sigma+1)$ if $q \equiv 2 \pmod 3$; and $\chi_{-3}(q) = \pm 1$ accordingly (Proposition 6.35(iii)). Since ± 1 is its own inverse, conjugation by A^{-1} acts by the same sign. (iv) The same with $\mathrm{tr}(a+b\tau) = 2a$ and $\tau^q = \tau$ or $\tau^3 = -\tau$ according to q mod 4. (v) is Proposition 6.44 with $m=3$, tensored with $\mathbb{Q}_\ell$ for V; and Proposition 6.43(ii) for $\ell \equiv 1 \pmod 3$. □

In the paper 6.46. Lemma lem:IV and the paragraph after it: "T_3E is a torsion-free module of $\mathbb{Z}_3$-rank 2 over the discrete valuation ring $\mathbb{Z}_3[X]/(X^2+X+1) \simeq \mathbb{Z}_3[\zeta_3]$, with X acting as σ, hence free of rank one over it" is Corollary 6.42(i), with σ the generator of $\rho_{E,3}(I_q)$, of order 3 and determinant 1 (Chapter 11); here $\mathbb{Z}_3[\sigma]$, the subring of $\mathrm{End}(T)$ generated by σ, is isomorphic to $\mathbb{Z}_3[X]/(X^2+X+1)$ because σ is not a scalar. "its image in $\mathrm{Aut}(E[3])$ is a nontrivial unipotent subgroup. Consequently $E[3]^{I_q}$ is a line" (statement of Lemma lem:IV) is Corollary 6.42(ii): $E[3] = T/3T \simeq \mathbb{Z}_3[\zeta_3]/(\pi^2)$, σ acts as multiplication by $\zeta_3 = 1-\pi$, and its fixed space is $\pi T/3T$. That $\mathbb{Z}_3[\zeta_3]$ is a discrete valuation ring with uniformiser $\pi = 1-\zeta_3$ and residue field $\mathbb{F}_3$ is Theorem 6.41; $\pi^2 = -3$ up to a unit is Proposition 6.39(i). The same freeness is used in Lemma lem:tamadd, with the basis in which $\sigma = \left(\begin{smallmatrix} 0 & -1 \\ 1 & -1 \end{smallmatrix}\right)$, the companion matrix of X^2+X+1 acting on the basis $t, \sigma t$ for a generator t. The paper states the freeness at every prime $q \neq 3$ at which $\rho_{E,3}(I_q)$ is cyclic of order 3, $q=2$ included; it holds wherever an element of order 3 generates the 3-Sylow subgroup of $\rho(I_q)$, as in Lemma lem:tamadd, since Corollary 6.42 needs only $\sigma^2+\sigma+1=0$. Only the identification of the order 3 with Kraus's semistability defect needs $q \geq 5$.

In the paper 6.47. Lemma lem:euler, types II, II*, IV, IV*: "the invariants form the line spanned by $2\sigma+1$, whose square is -3, inside $\mathrm{End}_{I_q}(T)=\mathbb{Z}_\ell[\sigma]\simeq\mathbb{Z}_\ell\otimes\mathbb{Z}[\zeta_3]$ (not a field when $\ell\equiv 1 \pmod 3$)". The invariants of I_q on $\mathrm{ad}^0 V$ are the trace-zero elements of $\mathrm{End}_{I_q}(V)$, the commutant of $\rho(I_q)=\langle\pm\sigma\rangle$, which is the line $\mathbb{Q}_\ell(2\sigma+1)$ of Proposition 6.45(ii); the integral statement is Proposition 6.45(v). "Frobenius ... acts on the line by $\chi_{-3}(q)$" is Proposition 6.45(iii) with $A=\rho(F)$ supplied by Corollary 6.32. Types III, III*: the line spanned by τ and the sign $\chi_{-4}(q)$, Proposition 6.45(iv); no diagonalisation of τ over $\mathbb{Q}_\ell$ is needed (it is impossible for $\ell\equiv 3 \pmod 4$, $\mathbb{Q}_\ell[i]$ being a field). The table entries $1-\chi_{-3}(q)q^{-s}$ and $1-\chi_{-4}(q)q^{-s}$ follow with either Frobenius (Convention 6.25). The two rings are kept apart: $\mathrm{End}_{I_q}(V)$ is the $\mathbb{Q}_\ell$-algebra $\mathbb{Q}_\ell\otimes\mathbb{Q}(\zeta_3)$, and $\mathbb{Z}_\ell\otimes\mathbb{Z}[\zeta_3]$ is the endomorphism ring $\mathrm{End}_{I_q}(T)$ of the lattice.

The quadratic characters met so far were defined through quadratic fields. The next section places them, together with the cyclotomic characters χ_ℓ and $\bar\chi_\ell$, inside the cyclotomic fields, and proves that the two descriptions of a character of finite order, as a Dirichlet character and as a character of $G_\mathbb{Q}$, are the same.

6.5 Cyclotomic fields and class field theory over $\mathbb{Q}$

The cyclotomic fields are where the characters of the paper live: χ_ℓ and $\bar\chi_\ell$ describe the action on μ_{ℓ^∞}, the quadratic characters χ_{-3}, χ_{-4}, χ_{q^*}, χ_S factor through $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})\simeq(\mathbb{Z}/n)^\times$, and the theorem of Kronecker and Weber says that every character of $G_\mathbb{Q}$ of finite order does. This section computes the splitting of primes in $\mathbb{Q}(\zeta_n)$, shows that $\mathbb{Q}(\sqrt{\ell^*})$ is the quadratic subfield of $\mathbb{Q}(\zeta_\ell)$ with its splitting law, and sets up the dictionary between Dirichlet characters and characters of $G_\mathbb{Q}$ that the paper uses in both directions: as Galois characters ($\rho\otimes\chi$ in Proposition prop:ns and Lemma lem:h0) and as Dirichlet characters ($a_n(g\otimes\chi)=\chi(n)a_n(g)$ in Lemma lem:twist(iii) and Theorems thm:twist and thm:qual). The Galois theory of $\mathbb{Q}(\zeta_n)$, $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})\simeq(\mathbb{Z}/n)^\times$, $a\mapsto\sigma_a$ with $\sigma_a(\zeta_n)=\zeta_n^a$, is in Chapter 5; the cyclotomic polynomials Φ_n and their factorisation modulo p are in Chapter 2.

Theorem 6.48 (rings of integers of cyclotomic fields)**.** *Let $n\geq 1$ and $K=\mathbb{Q}(\zeta_n)$, of degree $\varphi(n)$.*

(i) $\mathcal{O}_K=\mathbb{Z}[\zeta_n]$.

(ii) If $n=\ell^a$ with ℓ prime and $\zeta=\zeta_{\ell^a}$, then $\prod_{b\in(\mathbb{Z}/\ell^a)^\times}(1-\zeta^b)=\Phi_{\ell^a}(1)=\ell$, each $1-\zeta^b$ is a unit times $1-\zeta$, and $\ell\mathcal{O}_K=(1-\zeta)^{\varphi(\ell^a)}\mathcal{O}_K$: ℓ is totally ramified, and $(1-\zeta)$ is a prime with residue field $\mathbb{F}_\ell$.

(iii) $d_K=(-1)^{\varphi(n)/2}n^{\varphi(n)}/\prod_{p\mid n}p^{\varphi(n)/(p-1)}$*; in particular* $d(\mathbb{Q}(\zeta_\ell))=(-1)^{(\ell-1)/2}\ell^{\ell-2}$ *for an odd prime ℓ,* $d(\mathbb{Q}(\zeta_3))=-3$, $d(\mathbb{Q}(\zeta_4))=-4$, $d(\mathbb{Q}(\zeta_8))=256$.

(iv) For $n\not\equiv 2 \pmod 4$, a prime p ramifies in $\mathbb{Q}(\zeta_n)$ iff $p\mid n$. (Recall $\mathbb{Q}(\zeta_n)=\mathbb{Q}(\zeta_{2n})$ for n odd.)

Proof. We prove (i) and (ii) for $n=\ell^a$, (iii) for n an odd prime, and (iv) after Theorem 6.49; the general case of (i) and (iii) is stated, see [201, Chapter 2] or [142, Chapter I, Section 10] (the formula of (iii) was checked against PARI's `nfdisc` for $n\in\{3,4,5,7,8,9,12,15,16,20\}$). (ii) $\Phi_{\ell^a}(X)=\sum_{j=0}^{\ell-1}X^{j\ell^{a-1}}=\prod_b(X-\zeta^b)$, so $\prod_b(1-\zeta^b)=\Phi_{\ell^a}(1)=\ell$. For $\ell\nmid b$, $(1-\zeta^b)/(1-\zeta)=1+\zeta+\cdots+\zeta^{b-1}\in\mathbb{Z}[\zeta]$, and its inverse $(1-\zeta)/(1-\zeta^b)$ is of the same form since $\zeta=(\zeta^b)^{b'}$

with $bb' \equiv 1$. So $\ell = u(1-\zeta)^{\varphi(\ell^a)}$ with u a unit. Writing $(1-\zeta) = \prod \mathfrak{P}^{a_\mathfrak{P}}$, $\ell\mathcal{O}_K = \prod \mathfrak{P}^{\varphi(\ell^a)a_\mathfrak{P}}$ and $\sum_\mathfrak{P} \varphi(\ell^a)a_\mathfrak{P} f_\mathfrak{P} = \varphi(\ell^a)$ (Theorem 6.19) forces a single $\mathfrak{P}$ with $a_\mathfrak{P} = f_\mathfrak{P} = 1$. (i) for $n = \ell^a$: differentiating $(X^{\ell^{a-1}} - 1)\Phi_{\ell^a}(X) = X^{\ell^a} - 1$ and evaluating at ζ, where $\Phi_{\ell^a}(\zeta) = 0$ kills the term containing Φ_{ℓ^a}, gives $(\xi - 1)\Phi'_{\ell^a}(\zeta) = \ell^a\zeta^{\ell^a-1} = \ell^a\zeta^{-1}$ with $\xi = \zeta^{\ell^{a-1}}$ a primitive ℓ-th root of unity, whose norm $N_{K/\mathbb{Q}}(\xi - 1)$ is $\pm$ a power of ℓ by (ii). So $\operatorname{disc}(\Phi_{\ell^a}) = \pm N(\Phi'_{\ell^a}(\zeta))$ is $\pm$ a power of ℓ (Theorem 6.6(iv)), and the index $[\mathcal{O}_K : \mathbb{Z}[\zeta]]$ is a power of ℓ. Suppose ℓ divides it. Then some $x \in \mathcal{O}_K \setminus \mathbb{Z}[\zeta]$ has $\ell x \in \mathbb{Z}[\zeta]$. With $\pi_\ell = 1 - \zeta$, the elements $1, \pi_\ell, \dots, \pi_\ell^{\varphi-1}$ ($\varphi = \varphi(\ell^a)$) form a $\mathbb{Z}$-basis of $\mathbb{Z}[\zeta]$; write $\ell x = \sum_i c_i\pi_\ell^i$ with not all c_i divisible by ℓ, and let j be the least index with $\ell \nmid c_j$. Then $\sum_{i\ge j} c_i\pi_\ell^i = \ell x - \sum_{i<j} c_i\pi_\ell^i$ lies in $\ell\mathcal{O}_K = \pi_\ell^\varphi\mathcal{O}_K$ (the terms with $i < j$ have $c_i \in \ell\mathbb{Z}$, and $\ell x \in \ell\mathcal{O}_K$), so its valuation v_{π_ℓ}, the valuation at the prime (π_ℓ), is at least φ. Here $j < \varphi$: otherwise all c_i ($i < \varphi$) would be divisible by ℓ. But $v_{\pi_\ell}(c_j\pi_\ell^j) = j$, because an integer prime to ℓ lies in no prime above ℓ, and (π_ℓ) is the only such prime, so $v_{\pi_\ell}(c_j) = 0$; while the terms with $i > j$ have valuation $\ge i > j$. If $v(a) < v(b)$ then $v(a+b) = v(a)$, since $v(a+b) \ge v(a)$ and $v(a) = v((a+b)-b) \ge \min(v(a+b), v(b))$ (Theorem 6.13(iv)); so the sum has valuation exactly $j < \varphi$: a contradiction. Hence $\mathcal{O}_K = \mathbb{Z}[\zeta]$. (iii) for an odd prime ℓ: with $a = 1$, $(\zeta-1)\Phi'_\ell(\zeta) = \ell\zeta^{\ell-1}$, $N(\zeta - 1) = \prod_b(\zeta^b - 1) = \ell$ (as $\ell - 1$ is even) and $N(\ell\zeta^{\ell-1}) = \ell^{\ell-1}N(\zeta)^{\ell-1} = \ell^{\ell-1}$ (ζ is a unit of norm $\prod_b \zeta^b = \zeta^{\ell(\ell-1)/2} = 1$), so by multiplicativity $N(\Phi'_\ell(\zeta)) = \ell^{\ell-1}/\ell = \ell^{\ell-2}$, and Theorem 6.6(iv) with $n = \ell - 1$ gives $d = (-1)^{(\ell-1)(\ell-2)/2}\ell^{\ell-2}$. Since $(\ell-1)(\ell-2)/2 = \frac{\ell-1}{2}(\ell-2)$ with $\ell - 2$ odd, the sign is $(-1)^{(\ell-1)/2}$. For $\ell = 3, 5, 7$ this gives -3, 125 and $-7^5 = -16807$. □

Theorem 6.49 (splitting in cyclotomic fields)**.** *Let $n = p^a m$ with $p \nmid m$, and let f be the order of p in $(\mathbb{Z}/m)^\times$. In $\mathbb{Q}(\zeta_n)$ the prime p has $e = \varphi(p^a)$, residue degree f, and $g = \varphi(m)/f$ primes above it. Under $(\mathbb{Z}/n)^\times = (\mathbb{Z}/p^a)^\times \times (\mathbb{Z}/m)^\times$ the inertia group of p is $(\mathbb{Z}/p^a)^\times \times \{1\} = \operatorname{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}(\zeta_m))$ and the decomposition group is $(\mathbb{Z}/p^a)^\times \times \langle p\rangle$. For $p \nmid n$, $\operatorname{Frob}_p = \sigma_p$; so p splits completely iff $p \equiv 1 \pmod n$, and p is inert iff p generates $(\mathbb{Z}/n)^\times$ (possible only if this group is cyclic).*

Proof. First let $p \nmid n$. $\operatorname{disc}(\Phi_n)$ divides $\operatorname{disc}(X^n - 1) = \pm n^n$ (the discriminant of a product is the product of the discriminants times a square of a resultant), so $p \nmid \operatorname{disc}(\Phi_n)$; then p is unramified (Theorem 6.22, as $d_K \mid \operatorname{disc}(\Phi_n)$) and $p \nmid [\mathcal{O}_K : \mathbb{Z}[\zeta_n]]$ (Theorem 6.6(iii)). Modulo p, Φ_n is a product of $\varphi(n)/f$ distinct irreducible factors of degree f, the order of p modulo n (Chapter 2); Theorem 6.20 gives the splitting. For $x = \sum_i a_i\zeta_n^i \in \mathbb{Z}[\zeta_n]$, $\sigma_p(x) = \sum_i a_i\zeta_n^{pi} \equiv (\sum_i a_i\zeta_n^i)^p \pmod p$ (the binomial theorem modulo p and $a_i^p \equiv a_i$). A general $x \in \mathcal{O}_K$ has $kx \in \mathbb{Z}[\zeta_n]$ for the index k, which is prime to p, and then $k\sigma_p(x) \equiv (kx)^p \equiv kx^p \pmod{\mathfrak{P}}$; so $\sigma_p(x) \equiv x^p \pmod{\mathfrak{P}}$ for every $\mathfrak{P} \mid p$, and $\sigma_p = \operatorname{Frob}_p$ (Proposition 6.27). It has order f; it is trivial iff $p \equiv 1 \pmod n$, and generates the group iff p is inert. Now let $p \mid n$. In $\mathbb{Q}(\zeta_m)$, p has $(e, f, g) = (1, f, \varphi(m)/f)$; in $\mathbb{Q}(\zeta_{p^a})$ it has $(\varphi(p^a), 1, 1)$ (Theorem 6.48(ii)). Write (e', f', g') for the invariants of p in $\mathbb{Q}(\zeta_n)$, which contains both fields. By multiplicativity in towers (Theorem 6.19), e' is a multiple of $\varphi(p^a)$ (pass through $\mathbb{Q}(\zeta_{p^a})$) and f' a multiple of f (pass through $\mathbb{Q}(\zeta_m)$), and $g' \ge \varphi(m)/f$ because each of the $\varphi(m)/f$ primes of $\mathbb{Q}(\zeta_m)$ above p has at least one prime of $\mathbb{Q}(\zeta_n)$ above it, and these are distinct. As $e'f'g' = \varphi(n) = \varphi(p^a)\varphi(m) = \varphi(p^a) \cdot f \cdot \varphi(m)/f$, all three inequalities are equalities: $e' = \varphi(p^a)$, $f' = f$, $g' = \varphi(m)/f$. The inertia group has order $\varphi(p^a)$, and its image in $\operatorname{Gal}(\mathbb{Q}(\zeta_m)/\mathbb{Q})$ is the inertia group there, which is trivial (Theorem 6.24(ii)); so it is $\operatorname{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}(\zeta_m))$, of order $\varphi(p^a)$. The decomposition group contains it and maps onto the decomposition group $\langle p\rangle$ of $\mathbb{Q}(\zeta_m)$, so it is the full preimage $(\mathbb{Z}/p^a)^\times \times \langle p\rangle$. □

Proof of Theorem 6.48(iv). By Theorem 6.49, p ramifies iff $p \mid n$ and $\varphi(p^a) > 1$, and $\varphi(p^a) = 1$ only for $p^a = 2$, excluded when $n \not\equiv 2 \pmod 4$. □

Example 6.50. (Checked with PARI.) $n=3$: $p\equiv 1 \pmod 3$ splits, $p\equiv 2 \pmod 3$ is inert, 3 is ramified. $n=5$: 11 splits completely; 19 and 29 (order 2 modulo 5) give $f=g=2$; 2 and 3 (order 4) are inert. $n=7$: 2 has order 3 modulo 7, so $f=3$, $g=2$; 13 has order 2, so $f=2$, $g=3$; $29\equiv 1$ splits completely. $n=8$: 2 is totally ramified; 3, 5, 7 have $f=g=2$; 17 splits completely; $(\mathbb{Z}/8)^\times$ is not cyclic, so no prime is inert.

Proposition 6.51 ($\mathbb{Q}(\sqrt{\ell^*})$)**.** *Let ℓ be an odd prime and $\ell^* = (-1)^{(\ell-1)/2}\ell$.*

(i) $\mathbb{Q}(\sqrt{\ell^*})$ is the unique quadratic subfield of $\mathbb{Q}(\zeta_\ell)$ (Chapter 5); it is ramified only at ℓ, with discriminant ℓ^*.

(ii) For every prime $p\neq\ell$, including $p=2$, $\chi_{\ell^*}(\mathrm{Frob}_p) = \left(\frac{p}{\ell}\right)$: p splits in $\mathbb{Q}(\sqrt{\ell^*})$ iff p is a square modulo ℓ, and p is inert *iff p is a non-square modulo ℓ. The inert primes have density $\frac{1}{2}$ (Corollary 6.61).*

(iii) For $\ell=3$, $\mathbb{Q}(\sqrt{-3}) = \mathbb{Q}(\zeta_3)$, and the inert primes are the $p\equiv 2 \pmod 3$.

(iv) $\mathbb{Q}(\sqrt{\ell^*})$ is imaginary iff $\ell\equiv 3 \pmod 4$.

Proof. (i) $\mathrm{Gal}(\mathbb{Q}(\zeta_\ell)/\mathbb{Q}) \simeq \mathbb{F}_\ell^\times$ is cyclic of even order $\ell-1$, so it has a unique subgroup of index 2 and $\mathbb{Q}(\zeta_\ell)$ has a unique quadratic subfield M (Chapter 5). A prime $p\neq\ell$ is unramified in $\mathbb{Q}(\zeta_\ell)$ (Theorem 6.48(iv)), hence in M (ramification indices multiply in towers, Theorem 6.19); and some prime ramifies in $M\neq\mathbb{Q}$ (Theorem 6.22). So M is ramified exactly at ℓ, and Proposition 6.36(i) gives $M=\mathbb{Q}(\sqrt{\ell^*})$, of discriminant ℓ^*. For example $\mathbb{Q}(\zeta_5)\supset\mathbb{Q}(\sqrt{5})$, as $\zeta_5+\zeta_5^{-1} = \frac{-1+\sqrt{5}}{2}$, and $\mathbb{Q}(\zeta_7)\supset\mathbb{Q}(\sqrt{-7})$. (ii) In $\mathrm{Gal}(\mathbb{Q}(\zeta_\ell)/\mathbb{Q})\simeq\mathbb{F}_\ell^\times$, $\mathrm{Frob}_p=\sigma_p$ corresponds to p mod ℓ (Theorem 6.49). Its restriction to $\mathbb{Q}(\sqrt{\ell^*})$ is Frob_p there (Proposition 6.27(v)), which is trivial iff σ_p lies in the unique subgroup of index 2 of the cyclic group $\mathbb{F}_\ell^\times$, the squares. (iii) $\zeta_3 = (-1+\sqrt{-3})/2$. (iv) $\ell^*<0$ iff $(\ell-1)/2$ is odd. □

Corollary 6.52 (quadratic reciprocity, second proof)**.** *For distinct odd primes p,q: $\left(\frac{q^*}{p}\right) = \left(\frac{p}{q}\right)$, equivalently $\left(\frac{p}{q}\right)\left(\frac{q}{p}\right) = (-1)^{\frac{p-1}{2}\frac{q-1}{2}}$. Moreover $\left(\frac{-1}{p}\right) = (-1)^{(p-1)/2}$ and $\left(\frac{2}{p}\right) = (-1)^{(p^2-1)/8}$.*

Proof. $\chi_{q^*}(\mathrm{Frob}_p)$ equals $\left(\frac{q^*}{p}\right)$ by Proposition 6.35(i) together with Theorem 6.34 (whose proof uses only the meaning of the Legendre symbol, not reciprocity), and $\left(\frac{p}{q}\right)$ by Proposition 6.51(ii). Since $\left(\frac{q^*}{p}\right) = \left(\frac{-1}{p}\right)^{(q-1)/2}\left(\frac{q}{p}\right)$, the second form follows from the first supplement. For the supplements: $\mathbb{Q}(i)=\mathbb{Q}(\zeta_4)$, and $\sigma_p(i) = i^p = (-1)^{(p-1)/2}i$, so $\left(\frac{-4}{p}\right) = \chi_{-4}(\mathrm{Frob}_p) = (-1)^{(p-1)/2}$; and $\sqrt{2}=\zeta_8+\zeta_8^{-1}\in\mathbb{Q}(\zeta_8)$, with $\sigma_p(\sqrt{2}) = \zeta_8^p+\zeta_8^{-p}$, which is $\sqrt{2}$ if $p\equiv\pm1 \pmod 8$ and $-\sqrt{2}$ if $p\equiv\pm3 \pmod 8$; so $\left(\frac{8}{p}\right) = \left(\frac{2}{p}\right) = \chi_8(\mathrm{Frob}_p) = (-1)^{(p^2-1)/8}$. □

Chapter 2 proves reciprocity by Gauss sums; the proof above explains why the character of $\mathbb{Q}(\sqrt{q^*})$ is the Legendre symbol modulo q, which is what Lemma lem:twist means by χ_{q^*}, "the quadratic character of conductor q".

Theorem 6.53 (Kronecker-Weber)**.** *Every finite abelian extension $K/\mathbb{Q}$ is contained in $\mathbb{Q}(\zeta_n)$ for some n. The least such n with $n\not\equiv 2 \pmod 4$ is the* conductor *f_K of K, and the primes dividing f_K are exactly the primes ramified in K. Equivalently, the maximal abelian extension of $\mathbb{Q}$ is $\mathbb{Q}^{\mathrm{ab}} = \mathbb{Q}(\mu_\infty) = \bigcup_n \mathbb{Q}(\zeta_n)$, and the cyclotomic characters give $G_{\mathbb{Q}}^{\mathrm{ab}} = \mathrm{Gal}(\mathbb{Q}^{\mathrm{ab}}/\mathbb{Q}) \simeq \varprojlim_n (\mathbb{Z}/n)^\times = \hat{\mathbb{Z}}^\times = \prod_\ell \mathbb{Z}_\ell^\times$. For a quadratic field of discriminant D, $f_K = |D|$.*

Reference. We do not prove this; see [201, Chapter 14] or [142, Chapter V, Section 1, and Chapter VI] (chapter-level pointers). For a quadratic field the inclusion $K \subseteq \mathbb{Q}(\zeta_{|D|})$ is elementary (Chapter 5), and $f_K = |D|$ is Theorem 6.55(i) applied to the primitive character $n \mapsto (\frac{D}{n})$ of conductor $|D|$ (Chapter 2), which corresponds to χ_D by Proposition 6.35(i). □

Theorem 6.54 (Artin reciprocity over $\mathbb{Q}$, explicit form)**.** *Let $K/\mathbb{Q}$ be abelian with $K \subseteq \mathbb{Q}(\zeta_n)$.*

(i) The Artin map $\mathrm{Art}_K\colon (\mathbb{Z}/n)^\times \to \mathrm{Gal}(K/\mathbb{Q})$, $a \mapsto \sigma_a|_K$, *is surjective with kernel H_K, and $K \mapsto H_K$ is an inclusion-reversing bijection between the subfields of $\mathbb{Q}(\zeta_n)$ and the subgroups of $(\mathbb{Z}/n)^\times$.*

(ii) For every prime $p \nmid n$, $\mathrm{Frob}_p(K/\mathbb{Q}) = \mathrm{Art}_K(p \bmod n)$: the Frobenius of an unramified prime in an abelian extension depends only on $p \bmod n$. So $p \nmid n$ splits completely in K iff $p \bmod n \in H_K$, and the residue degree of p in K is the order of p in $(\mathbb{Z}/n)^\times/H_K$.

(iii) (Stated.) In idelic form, the global Artin map $\mathbb{Q}^\times\backslash\mathbb{A}_\mathbb{Q}^\times \to G_\mathbb{Q}^{\mathrm{ab}}$ is surjective with kernel the connected component of the identity, and $\mathbb{A}_\mathbb{Q}^\times = \mathbb{Q}^\times \cdot (\mathbb{R}_{>0} \times \hat{\mathbb{Z}}^\times)$. In the normalisation in which a uniformiser at p maps to an arithmetic Frobenius, an idele $(1, \dots, 1, u_p, 1, \dots)$ with $u_p \in \mathbb{Z}_p^\times$ maps to an element of the inertia group at p acting on μ_{p^∞} by u_p^{-1}. Deligne's normalisation sends uniformisers to geometric Frobenius elements, and then the sign is reversed.

Proof. (i) is Galois theory (Chapter 5) for $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \simeq (\mathbb{Z}/n)^\times$. (ii) By Proposition 6.27(v) and Theorem 6.49, $\mathrm{Frob}_p(K/\mathbb{Q}) = \mathrm{Frob}_p(\mathbb{Q}(\zeta_n)/\mathbb{Q})|_K = \sigma_p|_K$; the residue degree is the order of Frob_p (Proposition 6.27(i)). (iii) We do not prove this; see [142, Chapter VI, Sections 5 and 6] or [133, Chapter V]; nothing in the paper needs it. □

Theorem 6.55 (Dirichlet characters and characters of $G_\mathbb{Q}$)**.** *(i) Let χ be a primitive Dirichlet character, of conductor f_χ (Chapter 2), and let ψ_χ be the composite*

$$G_\mathbb{Q} \to \mathrm{Gal}(\mathbb{Q}(\zeta_{f_\chi})/\mathbb{Q}) \simeq (\mathbb{Z}/f_\chi)^\times \xrightarrow{\chi} \mathbb{C}^\times.$$

Then $\psi_\chi(\mathrm{Frob}_p) = \chi(p)$ for every prime $p \nmid f_\chi$, and $\chi \mapsto \psi_\chi$ is a bijection from primitive Dirichlet characters to continuous homomorphisms $G_\mathbb{Q} \to \mathbb{C}^\times$ (these have finite image, Chapter 5). Each ψ is determined by its values at the Frob_p, $p \nmid f_\chi$. The field cut out by ψ_χ has conductor f_χ, and $\psi_{\chi\chi'} = \psi_\chi\psi_{\chi'}$ when $\chi\chi'$ denotes the primitive character inducing the product.

(ii) ψ_χ is unramified at p iff $p \nmid f_\chi$. More precisely, if $f_\chi = p^a m$ with $p \nmid m$, then $\psi_\chi(I_p) = \chi((\mathbb{Z}/p^a)^\times \times \{1\})$.

(iii) The same holds for characters with values in $\overline{\mathbb{Q}}_\ell^\times$ or $\overline{\mathbb{F}}_\ell^\times$ of finite order (through a fixed embedding of roots of unity), and every continuous $\psi\colon G_\mathbb{Q} \to \mathbb{Z}_\ell^\times$ factors through $G_\mathbb{Q}^{\mathrm{ab}} \simeq \hat{\mathbb{Z}}^\times$; for instance χ_ℓ is the projection $\hat{\mathbb{Z}}^\times \to \mathbb{Z}_\ell^\times$, and $\bar{\chi}_\ell = \psi_{\omega_\ell}$ for the character $\omega_\ell\colon a \mapsto a \bmod \ell$ of $(\mathbb{Z}/\ell)^\times$.

(iv) (Stated; Chapters 13 and 15.) Under this dictionary, twisting a newform's coefficients, $a_n \mapsto \chi(n)a_n$, corresponds to tensoring its Galois representation with ψ_χ.

Proof. (i) $\psi_\chi(\mathrm{Frob}_p) = \chi(p)$ by Theorem 6.49. Injectivity: $G_\mathbb{Q} \to (\mathbb{Z}/f_\chi)^\times$ is surjective, so ψ_χ determines χ on $(\mathbb{Z}/f_\chi)^\times$, and ψ_χ determines f_χ as below. Surjectivity: a continuous $\psi\colon G_\mathbb{Q} \to \mathbb{C}^\times$ has finite abelian image, and its kernel cuts out a finite abelian extension, contained in some $\mathbb{Q}(\zeta_n)$ (Theorem 6.53); so ψ factors as $G_\mathbb{Q} \to (\mathbb{Z}/n)^\times \xrightarrow{\chi'} \mathbb{C}^\times$, and $\psi = \psi_\chi$ for the primitive χ inducing χ' (restriction from $\mathbb{Q}(\zeta_n)$ to $\mathbb{Q}(\zeta_{f_\chi})$ is reduction $(\mathbb{Z}/n)^\times \to (\mathbb{Z}/f_\chi)^\times$). That ψ is determined by its values at Frobenius elements outside a finite set follows from the density of Frobenius elements (Corollary 6.61), or directly from Dirichlet's theorem on primes in progressions. The field K cut out by ψ_χ lies in $\mathbb{Q}(\zeta_{f_\chi})$; if it lay in $\mathbb{Q}(\zeta_{f'})$ with $f' \mid f_\chi$, $f' < f_\chi$, then χ would be trivial on the kernel of $(\mathbb{Z}/f_\chi)^\times \to (\mathbb{Z}/f')^\times$, hence induced from a character modulo f', contradicting primitivity; and if $K \subseteq \mathbb{Q}(\zeta_n)$ then $K \subseteq \mathbb{Q}(\zeta_n) \cap \mathbb{Q}(\zeta_{f_\chi}) = \mathbb{Q}(\zeta_{\gcd(n,f_\chi)})$ (the intersection contains $\mathbb{Q}(\zeta_{\gcd})$ and has degree $\varphi(n)\varphi(f_\chi)/\varphi(\mathrm{lcm}) = \varphi(\gcd)$, by Galois theory of the compositum $\mathbb{Q}(\zeta_{\mathrm{lcm}})$). So the least n is f_χ, which is $\not\equiv 2 \pmod 4$ for a primitive character. Multiplicativity is clear on a common modulus. (ii) By Theorem 6.49 the image of I_p in $\mathrm{Gal}(\mathbb{Q}(\zeta_{f_\chi})/\mathbb{Q})$ is $(\mathbb{Z}/p^a)^\times \times \{1\}$; χ is nontrivial on it when $a \geq 1$, by primitivity (otherwise χ would factor through $(\mathbb{Z}/m)^\times$). (iii) The same proofs; the factorisation through $\hat{\mathbb{Z}}^\times$ is Theorem 6.53, since a continuous homomorphism to the abelian group $\mathbb{Z}_\ell^\times$ factors through $G_\mathbb{Q}^{\mathrm{ab}}$. $\bar\chi_\ell(\mathrm{Frob}_p) = p \bmod \ell = \omega_\ell(p)$. (iv) We do not prove this here; see Chapters 13 and 15. □

Example 6.56 (the paper's characters in both languages)**.** For p unramified (arithmetic Frobenius):

Galois character	field cut out	Dirichlet character	conductor	value at Frob_p
χ_{-4}	$\mathbb{Q}(i) = \mathbb{Q}(\zeta_4)$	the nontrivial character mod 4	4	$(-1)^{(p-1)/2}$
$\chi_{-3} = \bar\chi_3^{\mathrm{cyc}}$	$\mathbb{Q}(\sqrt{-3}) = \mathbb{Q}(\zeta_3)$	$\left(\frac{\cdot}{3}\right)$	3	1 iff $p \equiv 1 \pmod 3$
χ_{q^*}, q odd	$\mathbb{Q}(\sqrt{q^*}) \subseteq \mathbb{Q}(\zeta_q)$	$\left(\frac{\cdot}{q}\right)$	q	$\left(\frac{p}{q}\right)$
$\chi_S = \prod_{q\in S} \chi_{q^*}$	$\mathbb{Q}\left(\sqrt{\prod_{q\in S} q^*}\right)$	$\prod_{q\in S}\left(\frac{\cdot}{q}\right)$	$\prod_{q\in S} q$	$\prod_{q\in S}\left(\frac{p}{q}\right)$
$\chi_{\ell^*} = \bar\chi_\ell^{(\ell-1)/2}$	$\mathbb{Q}(\sqrt{\ell^*})$	$\left(\frac{\cdot}{\ell}\right)$	ℓ	$\left(\frac{p}{\ell}\right)$
$\bar\chi_\ell$ (values in $\mathbb{F}_\ell^\times$)	$\mathbb{Q}(\zeta_\ell)$	$\omega_\ell\colon a \mapsto a \bmod \ell$	ℓ	$p \bmod \ell$

The identity $\chi_{\ell^*} = \bar\chi_\ell^{(\ell-1)/2}$ means: the quadratic character $\left(\frac{\cdot}{\ell}\right)$ equals $a \mapsto a^{(\ell-1)/2} \bmod \ell$ (Euler's criterion), read in $\{\pm 1\} \subset \mathbb{F}_\ell^\times$. The Dirichlet character $\left(\frac{\cdot}{q}\right)$ equals $\left(\frac{q^*}{\cdot}\right)$ by quadratic reciprocity (Chapter 2), so the two descriptions of the column agree.

Warning 6.57. χ_{ℓ^*} and $\bar\chi_\ell$ coincide only for $\ell = 3$: for $\ell \geq 5$, $\bar\chi_\ell$ has order $\ell - 1 > 2$. The cyclotomic character χ_ℓ itself has infinite image $\mathbb{Z}_\ell^\times$. So "$\rho \simeq \rho \otimes \chi_\ell$" (impossible for every two-dimensional ρ: taking determinants, $\chi_\ell^2 = 1$, while $\chi_\ell(G_\mathbb{Q}) = \mathbb{Z}_\ell^\times$ is infinite), "$\bar\rho \simeq \bar\rho \otimes \bar\chi_\ell$" (possible only for $\ell = 3$, by determinants: $\bar\chi_\ell^2 = 1$ forces $\ell - 1 \mid 2$) and "$\bar\rho \simeq \bar\rho \otimes \chi_{\ell^*}$" (a statement about the quadratic field $\mathbb{Q}(\sqrt{\ell^*})$, Proposition 6.62) are three different conditions. The paper's term $h_\ell(E)$ (Lemma lem:h0) is governed by the second, and the hypothesis of Theorem thm:main by the third.

In the paper 6.58. Section 1.4 and Lemma lem:twist: $E^{(q)}$ is the twist by χ_{q^*}, "the quadratic character of conductor q", that is by $\mathbb{Q}(\sqrt{q^*})$; it is the character $\left(\frac{\cdot}{q}\right)$ of Example 6.56, ramified only at q (Proposition 6.36), which is why Lemma lem:twist(i) holds at every $p \neq q$. Theorems thm:twist and thm:quant: $\chi_S = \prod_{q\in S} \chi_{q^*}$ and $\prod_{q\in S} q$ (the paper's D) are the character and the conductor of $\mathbb{Q}(\sqrt{\prod_{q\in S} q^*})$ (Proposition 6.36(iii)), and "the twist is unramified outside S" is Proposition 6.36(iv). The map $\iota\colon h \mapsto \sum \chi_S(n) a_n(h) q^n$ uses χ_S as a Dirichlet character, and

$\rho_{E_S} \simeq \rho_E \otimes \chi_S$ uses it as a Galois character; the two are the same character by Theorem 6.55. The table of Section 1 uses $\chi_{-3}(q)$ and $\chi_{-4}(q)$ as values of Dirichlet characters, equal to the Galois values at Frob_q (Proposition 6.35(iii)), which is how they enter the proof of Lemma lem:euler. Proposition prop:forms uses $q \equiv \chi_{-3}(q) \pmod 3$, which holds for every prime $q \neq 3$ by Proposition 6.35(iii).

Up to now every statement about Frobenius elements has concerned one prime at a time. The next section asks how the Frobenius classes are distributed as p varies; the answer, Chebotarev's theorem, is what allows a representation to be recognised from its traces of Frobenius.

6.6 Densities, the Chebotarev density theorem, complex multiplication

The paper uses Chebotarev's theorem to compare Galois representations through their Frobenius traces (Lemma lem:old, "by Chebotarev and Brauer-Nesbitt"). The opposite direction needs no density theorem: in Section 3 of the paper the optimal-level theorem gives $\bar\rho_g \simeq \bar\rho$, and $a_p(g) \equiv a_p(f)$ for all $p \nmid 3N$ follows by taking traces of Frobenius (Proposition 6.30(iv)). This section states the theorem with the Frobenius of Proposition 6.27 and over any number field, proves the corollaries the book needs, gives the criterion for a representation to be isomorphic to its twist by a quadratic character, and explains why $a_p(E) = 0$ at the inert primes of a quadratic field happens only for curves with complex multiplication by that field. The form of Chebotarev over $\mathbb{Q}$ and its Brauer-Nesbitt corollaries are in Chapter 5.

Proposition 6.59 (the Dedekind zeta function and densities)**.** *Let K be a number field of degree n.*

(i) $\zeta_K(s) = \sum_{\mathfrak{a}} N\mathfrak{a}^{-s} = \prod_{\mathfrak{p}} (1 - N\mathfrak{p}^{-s})^{-1}$ *(sum over the nonzero ideals, product over the nonzero primes) converges absolutely for* $\operatorname{Re} s > 1$.

(ii) (Stated.) ζ_K *extends meromorphically to* $\operatorname{Re} s > 1 - 1/n$ *with a simple pole at* $s = 1$*, whose residue is given by the analytic class number formula.*

(iii) Given (ii): $\sum_{\mathfrak{p}} N\mathfrak{p}^{-s} \sim \log \frac{1}{s-1}$ *as* $s \to 1^+$*. So the* Dirichlet density *of a set X of primes of K,* $\delta(X) = \lim_{s\to 1^+} \sum_{\mathfrak{p}\in X} N\mathfrak{p}^{-s} / \log \frac{1}{s-1}$ *when the limit exists, is defined as in Chapter 5 with $N\mathfrak{p}$ in place of p. The primes $\mathfrak{p}$ with $f(\mathfrak{p} \mid p) \geq 2$ have density* 0*, so the primes of degree one have density* 1*; finite sets have density* 0.

Proof. (i) By unique factorisation (Theorem 6.13) and multiplicativity of the norm (Proposition 6.14), the expansion of the finite products $\prod_{N\mathfrak{p}\leq x}(1 - N\mathfrak{p}^{-s})^{-1}$ contains each $N\mathfrak{a}^{-s}$ with $\mathfrak{a}$ composed of these primes exactly once. For real $s = \sigma > 1$, at most n primes lie above each rational p, each with $N\mathfrak{p} \geq p$ (Theorem 6.19), so $\prod_{\mathfrak{p}}(1-N\mathfrak{p}^{-\sigma})^{-1} \leq \prod_p (1-p^{-\sigma})^{-n} = \zeta(\sigma)^n < \infty$; this bounds all partial sums of the series of positive terms. (ii) We do not prove this; see [142, Chapter VII, Section 5] or [108, Chapter VIII]. (iii) $\log \zeta_K(s) = \sum_{\mathfrak{p}} \sum_{m\geq 1} N\mathfrak{p}^{-ms}/m$ (take logarithms in the Euler product, $-\log(1-x) = \sum_m x^m/m$), and for real $s > 1$ the terms with $m \geq 2$ are bounded by $n \sum_p \sum_{m\geq 2} p^{-m} = n \sum_p \frac{p^{-2}}{1-p^{-1}} \leq n \sum_p \frac{2}{p^2} < \infty$; so $\log \zeta_K(s) = \sum_{\mathfrak{p}} N\mathfrak{p}^{-s} + O(1)$. By (ii) $\zeta_K(s) = \frac{c}{s-1}(1 + o(1))$ as $s \to 1^+$ with $c > 0$ the residue (positive, as $\zeta_K(s) > 0$ for real $s > 1$), so $\log \zeta_K(s) = \log \frac{1}{s-1} + \log c + o(1)$, which gives the asymptotic. The primes with $f \geq 2$ have $N\mathfrak{p} \geq p^2$, and $\sum_{f(\mathfrak{p})\geq 2} N\mathfrak{p}^{-s} \leq n \sum_p p^{-2}$ stays bounded. □

Theorem 6.60 (Chebotarev density theorem)**.** *Let L/K be a finite Galois extension of number fields with group G and $C \subseteq G$ a conjugacy class. The set of primes $\mathfrak{p}$ of K, unramified in L, with $\mathrm{Frob}_\mathfrak{p} = C$ (Proposition 6.27(ii)) has Dirichlet density $\#C/\#G$. It also has natural density $\#C/\#G$ (counting the primes with $N\mathfrak{p} \le x$). For G abelian the classes are elements, and the statement contains Dirichlet's theorem on primes in arithmetic progressions.*

Reference. We do not prove this; see [142, Chapter VII, Section 13] (the theorem is numbered 13.4 there; this number and the others in this chapter are pointers not checked against a printed copy) or [178, Chapter I, Section 2.2]. The idea: for G cyclic it follows from the nonvanishing at $s = 1$ of the Hecke L-functions of K (abelian class field theory), and the general case reduces to the cyclic one by restricting to the cyclic subgroup generated by an element of C. Only the Dirichlet density is used in this book; the natural density is not used in any proof. □

Corollary 6.61. *In the setting of Theorem 6.60:*

(i) every $\sigma \in G$ is $\mathrm{Frob}_\mathfrak{P}$ for infinitely many $\mathfrak{P}$ (lying over a set of primes $\mathfrak{p}$ of positive density);

(ii) the primes of K that split completely in L have density $1/[L : K]$; if M/K is a finite extension, not necessarily Galois, the primes of K having a prime of degree one above them in M have positive density;

(iii) (Bauer) for L, L' Galois over K: $L \subseteq L'$ iff every prime of K that splits completely in L', outside a set of density zero, splits completely in L; so a Galois extension of K is determined by its set of split primes;

(iv) (Dirichlet) for $K = \mathbb{Q}$, $L = \mathbb{Q}(\zeta_n)$: each class $a \in (\mathbb{Z}/n)^\times$ contains a set of primes of density $1/\varphi(n)$;

(v) for $L/\mathbb{Q}$ quadratic, the split and the inert primes each have density $\frac{1}{2}$; in particular the primes inert in $\mathbb{Q}(\sqrt{\ell^*})$ (the p with $\left(\frac{p}{\ell}\right) = -1$) have density $\frac{1}{2}$, and for $\ell = 3$ these are the $p \equiv 2 \pmod 3$;

(vi) if $L/\mathbb{Q}$ is Galois, possibly infinite, and unramified outside a finite set, the Frobenius elements at the primes outside any set of density zero are dense in $\mathrm{Gal}(L/\mathbb{Q})$ (Chapter 5).

Proof. (i) Take the class of σ; a set of positive density is infinite (finite sets have density 0), and for each such $\mathfrak{p}$ some $\mathfrak{P} \mid \mathfrak{p}$ has $\mathrm{Frob}_\mathfrak{P} = \sigma$ (Proposition 6.27(ii)). (ii) $C = \{1\}$ and Proposition 6.27(iii). For M, let L be a Galois closure of M/K, $G = \mathrm{Gal}(L/K)$, $H = \mathrm{Gal}(L/M)$; by Proposition 6.28 (whose proof is the same over K), $\mathfrak{p}$ unramified in L has a degree-one prime in M iff $\langle \mathrm{Frob}_\mathfrak{P} \rangle$ fixes a point of G/H, which holds when $\mathrm{Frob}_\mathfrak{P} = 1$; so the set contains the split primes, of density $1/[L : K] > 0$. (iii) If $L \subseteq L'$, a prime split completely in L' is split completely in L (Theorem 6.19). Conversely, consider the compositum LL', Galois over K, and the injection $\mathrm{Gal}(LL'/K) \to \mathrm{Gal}(L/K) \times \mathrm{Gal}(L'/K)$ by restriction, which sends $\mathrm{Frob}_\mathfrak{P}$ to the pair of Frobenius elements (Proposition 6.27(v)). So a prime unramified in LL' splits completely in LL' iff it splits completely in L and in L'; by hypothesis this is the set of primes splitting completely in L', up to density zero. By (ii), $1/[LL' : K] = 1/[L' : K]$, so $LL' = L'$ and $L \subseteq L'$. (iv) $\mathrm{Frob}_p = \sigma_p$ corresponds to $p \bmod n$ (Theorem 6.49), and $\#G = \varphi(n)$. (v) G has two classes of size 1; for $\mathbb{Q}(\sqrt{\ell^*})$ use Proposition 6.51(ii). (vi) is proved in Chapter 5 from Theorem 6.60. □

Proposition 6.62 (detecting a quadratic twist)**.** *Let k be a field of characteristic $\neq 2$ (a finite field, $\overline{\mathbb{F}}_\ell$, or a finite extension of $\mathbb{Q}_\ell$), $\rho\colon G_{\mathbb{Q}} \to \mathrm{GL}_2(k)$ continuous, semisimple, unramified outside a finite set S, and K a quadratic field with character χ_K. The following are equivalent: (a) $\rho \simeq \rho \otimes \chi_K$; (b) $\operatorname{tr}\rho(\mathrm{Frob}_p) = 0$ for every prime $p \notin S$ inert in K; (c) $\operatorname{tr}\rho(\mathrm{Frob}_p) = 0$ for all primes inert in K outside a set of density zero.*

Proof. (a)⇒(b): for $p \notin S$ unramified in K and inert, $\operatorname{tr}\rho(\mathrm{Frob}_p) = \operatorname{tr}(\rho\otimes\chi_K)(\mathrm{Frob}_p) = \chi_K(\mathrm{Frob}_p)\operatorname{tr}\rho(\mathrm{Frob}_p) = -\operatorname{tr}\rho(\mathrm{Frob}_p)$, and 2 is invertible in k; a prime inert in K is unramified in K. (b)⇒(c) is trivial. (c)⇒(a): $\rho\otimes\chi_K$ is semisimple (it has the same invariant subspaces as ρ, χ_K acting by scalars) and unramified outside S and the primes ramified in K. For p outside this finite set, $\det(X - (\rho\otimes\chi_K)(\mathrm{Frob}_p)) = X^2 - \chi_K(\mathrm{Frob}_p)\operatorname{tr}\rho(\mathrm{Frob}_p)X + \det\rho(\mathrm{Frob}_p)$, which equals $\det(X-\rho(\mathrm{Frob}_p))$ when p splits, and when p is inert and $\operatorname{tr}\rho(\mathrm{Frob}_p)=0$. By (c) the characteristic polynomials agree at all primes outside a set of density zero, so $\rho \simeq \rho\otimes\chi_K$ by the Chebotarev and Brauer-Nesbitt theorem of Chapter 5 (both being semisimple). □

Two applications. (a) If $\bar\rho_{E,3}$ is irreducible, then $\bar\rho_{E,3} \simeq \bar\rho_{E,3}\otimes\chi_{-3}$ iff $3 \mid a_p(E)$ for all primes $p \equiv 2 \pmod 3$ of good reduction (outside a density zero set), since $\operatorname{tr}\bar\rho_{E,3}(\mathrm{Frob}_p) = a_p \bmod 3$ and the inert primes of $\mathbb{Q}(\sqrt{-3})$ are the $p \equiv 2 \pmod 3$ (Chapter 5 gives the example $y^2 = x^3 - 6x - 8$). (b) If $\rho_{E,\ell}$ is semisimple (it always is, by Faltings's theorem, stated in Chapter 11; and it is irreducible when $\bar\rho_{E,\ell}$ is), then $\rho_{E,\ell} \simeq \rho_{E,\ell}\otimes\chi_K$ iff $a_p(E) = 0$ for almost all p inert in K (outside a density zero set). The criterion concerns twisting by a quadratic character; it says nothing about $\rho\otimes\chi_\ell$, which is never isomorphic to ρ (Warning 6.57).

Theorem 6.63 (complex multiplication)**.** *Let $E/\mathbb{Q}$ be an elliptic curve with complex multiplication, that is $\mathrm{End}_{\overline{\mathbb{Q}}}(E) \neq \mathbb{Z}$. Then $\mathrm{End}_{\overline{\mathbb{Q}}}(E)$ is an order $\mathcal{O}$ in an imaginary quadratic field K, the endomorphisms are defined over K, and $\sigma \in G_{\mathbb{Q}}$ acts on them through $\mathrm{Gal}(K/\mathbb{Q})$, by complex conjugation of $\mathcal{O} \subset K$ when $\chi_K(\sigma) = -1$ (Chapter 9).*

(i) (Stated.) $\mathcal{O}$ has class number one; so $K = \mathbb{Q}(\sqrt{-d})$ with $d \in \{1,2,3,7,11,19,43,67,163\}$, and $j(E)$ is one of 13 rational values.

(ii) For every prime ℓ, $\rho_{E,\ell} \simeq \rho_{E,\ell}\otimes\chi_K$, and $a_p(E) = 0$ for every prime p of good reduction inert in K.

(iii) Every prime ramified in K is a prime of bad reduction of E.

(iv) (Stated.) Conversely, if $a_p(E) = 0$ for all primes p inert in a quadratic field K outside a set of density zero, then E has complex multiplication by K; in particular K is imaginary.

(v) (Stated.) If E has no complex multiplication, the set of primes p with $a_p(E) = 0$ has density 0.

(vi) Consequently, for an odd prime ℓ, the condition "$a_p(E) = 0$ for almost all p inert in $\mathbb{Q}(\sqrt{\ell^*})$" holds if and only if E has complex multiplication by $\mathbb{Q}(\sqrt{\ell^*})$; this needs $\ell \equiv 3 \pmod 4$ and $\ell \in \{3,7,11,19,43,67,163\}$, and then ℓ divides the conductor of E by (iii). It never happens when $\ell \nmid N$.

Sketch of proof. The structure of $\mathrm{End}_{\overline{\mathbb{Q}}}(E)$ and the Galois action, $\rho_{E,\ell}(\sigma)\alpha\rho_{E,\ell}(\sigma)^{-1} = \sigma(\alpha)$ on $V_\ell E$ for $\alpha \in \mathrm{End}_{\overline{\mathbb{Q}}}(E)$, are quoted from Chapter 9 and [184, Chapter II, Section 2]. (ii) Choose $\alpha \in \mathcal{O}$ with $\bar\alpha = -\alpha$, $\alpha \neq 0$ (for instance $\alpha = f\sqrt{-d}$ for a suitable integer f); it acts

invertibly on $V_\ell E$, and $\rho(\sigma)\alpha\rho(\sigma)^{-1} = \sigma(\alpha) = \chi_K(\sigma)\alpha$. So $\alpha\rho(\sigma)\alpha^{-1} = \chi_K(\sigma)\rho(\sigma)$: α is an isomorphism $\rho \to \rho \otimes \chi_K$. For $p \neq \ell$ of good reduction and inert in K, $\chi_K(\mathrm{Frob}_p) = -1$ gives $a_p = \operatorname{tr}\rho(\mathrm{Frob}_p) = -a_p$, so $a_p = 0$ (choose $\ell \neq p$, and $a_p \in \mathbb{Z}$). (iii) If p is ramified in K and E had good reduction at p, take $\ell \neq p$: ρ is unramified at p, and there is $\tau \in I_p$ with $\chi_K(\tau) = -1$ (Proposition 6.35(ii)); then $\alpha = \rho(\tau)\alpha\rho(\tau)^{-1} = \chi_K(\tau)\alpha = -\alpha$, a contradiction. (i) is the theorem of Heegner, Baker and Stark on imaginary quadratic fields of class number one, together with the fact that $j(E) \in \mathbb{Q}$ generates the ring class field of $\mathcal{O}$; see [184, Chapter II and Appendix A] and [34, Sections 7, 11 and 12]. (iv) We only indicate the argument. Let L be the compositum of K and the field cut out by $\rho_{E,\ell}$, unramified outside $\ell N d_K$. By Corollary 6.61(vi) the Frobenius elements of $\mathrm{Gal}(L/\mathbb{Q})$ at the primes outside the exceptional set of density zero are dense, so those at the inert such primes are dense in the open coset $\mathrm{Gal}(L/\mathbb{Q}) \setminus \mathrm{Gal}(L/K)$; the trace of $\rho_{E,\ell}$ is continuous and vanishes at them, so it vanishes on $G_\mathbb{Q} \setminus G_K$. If E had no complex multiplication, the image of $\rho_{E,\ell}$ would be open in $\mathrm{GL}_2(\mathbb{Z}_\ell)$ (Serre's open image theorem [171]), and the trace cannot vanish on a coset of an open subgroup of index 2 of an open subgroup of $\mathrm{GL}_2(\mathbb{Z}_\ell)$ (such a coset contains elements g and $(1+\ell^k x)g$ for all $x \in \mathrm{M}_2(\mathbb{Z}_\ell)$ and k large, and $\operatorname{tr}(xg)$ is not identically zero). So E has complex multiplication by some K'. If $K' \neq K$, a set of primes of positive density splits in K' and is inert in K (Corollary 6.61(i) in KK'); at such a prime of good reduction the reduction is ordinary (Deuring's criterion, [34, Section 14]), so $a_p \not\equiv 0 \pmod p$ and $a_p \neq 0$, a contradiction. (v) is due to Serre [175, Section 7]. (vi) The forward implication is (iv); the converse is (ii). The class number one list and $\ell^* < 0$ (needed for K imaginary, Proposition 6.51(iv)) give the list of ℓ, and ℓ is ramified in $\mathbb{Q}(\sqrt{\ell^*})$. □

Example 6.64 (curves with complex multiplication)**.** (Checked with PARI: $a_p = 0$ at every good prime p inert in the field among the first 70 primes, and $a_p \neq 0$ at the split primes listed.) $y^2 = x^3 - x$, conductor 32, CM by $\mathbb{Z}[i]$: $a_p = 0$ for $p \equiv 3 \pmod 4$, and $a_5 = -2$, $a_{13} = 6$, $a_{17} = 2$, $a_{29} = -10$, $a_{37} = -2$. $y^2 = x^3 + 1$ (36a1) and $y^2 + y = x^3 - 7$ (27a1), $j = 0$, CM by $\mathbb{Z}[\zeta_3]$: $a_p = 0$ for $p \equiv 2 \pmod 3$; for 36a1, $a_{13} = 2$, $a_{37} = -10$. 121b1 $= [0, -1, 1, -7, 10]$, $j = -2^{15}$, CM by the maximal order of $\mathbb{Q}(\sqrt{-11}) = \mathbb{Q}(\sqrt{11^*})$: $a_p = 0$ when $\left(\frac{p}{11}\right) = -1$, for example $a_2 = a_7 = 0$, while $a_5 = -3$, $a_{37} = 7$. In each case the primes ramified in K (2, 3, 3, 11) divide the conductor, as Theorem 6.63(iii) requires.

In the paper 6.65. Lemma lem:h0: $H^0(\mathbb{Q}, W^D)$ is finite and cyclic, of length $h_\ell(E)$, "Moreover $h_\ell(E) = 0$ for every $\ell \geq 5$, and $h_3(E) \leq 1$", and "This holds for every E, with or without complex multiplication". The proof is the determinant argument (Chapters 4 and 5): an isomorphism $\rho \bmod \ell^k \simeq (\rho \otimes \chi_\ell) \bmod \ell^k$ forces $\chi_\ell^2 \equiv 1 \pmod{\ell^k}$; it uses neither complex multiplication nor the distribution of inert primes. The condition $\rho \simeq \rho \otimes \chi_\ell$ is not the condition $\rho \simeq \rho \otimes \chi_{\ell^*}$ (Warning 6.57); the statements about $a_p = 0$ at inert primes belong to the second and are Proposition 6.62 and Theorem 6.63, and by Theorem 6.63(vi) the complex multiplication case of the second cannot occur when $\ell \nmid N$. The equality $h_3(E) = 1$ holds "if and only if $\bar\rho_{E,3} \simeq \bar\rho_{E,3} \otimes \chi_{-3}$", which uses $\bar\chi_3^{\mathrm{cyc}} = \chi_{-3}$ (Example 6.56); its link with the reducibility of $\bar\rho|_{G_{\mathbb{Q}(\sqrt{-3})}}$, like Proposition prop:ns, obtains $\bar\rho \simeq \bar\rho \otimes \chi_{-3}$ from $\bar\rho \otimes \overline{\mathbb{F}}_3 \simeq \operatorname{Ind}\psi$ for a character ψ of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\sqrt{-3}))$, by Frobenius reciprocity and $\operatorname{Ind}\psi \otimes \chi_{-3} \simeq \operatorname{Ind}\psi$ (Chapter 4), not from Frobenius traces. Application (a) of Proposition 6.62 gives the equivalent trace criterion ($3 \mid a_p$ for almost all $p \equiv 2 \pmod 3$), used in the example of Chapter 5, not in the paper. Section sec:anomaly takes the values of $h_3(E)$ from Lemma lem:h0 and Proposition prop:ns.

The last section returns from Galois groups to rings: the coefficients of an eigenform, the primes λ above ℓ in its coefficient ring, and the maximal ideals of a Hecke algebra that congruences

between eigenforms produce.

6.7 Coefficient fields and primes above ℓ

Lemmas lem:crit and lem:old of the paper work with eigenforms whose coefficients lie in "the ring of integers $\mathcal{O}$ of a number field", with "a prime $\lambda \mid \ell$ of $\mathcal{O}$", with congruences modulo λ, with "a maximal ideal of residue characteristic ℓ" of the Hecke algebra, and with the operation "after enlarging $\mathcal{O}$ and λ". This section makes each of these precise. The Hecke algebra $\mathbb{T}$ itself, and the facts that its eigencharacters correspond to eigenforms, are in Chapters 12 and 13; here only the algebra of a commutative ring that is finitely generated as a $\mathbb{Z}$-module is used.

Proposition 6.66 (coefficient fields)**.** *Let R be a commutative ring, finitely generated as a $\mathbb{Z}$-module, and $\phi\colon R \to \mathbb{C}$ a ring homomorphism. Then every $\phi(t)$ is an algebraic integer, $K_\phi = \mathbb{Q}(\phi(R))$ is a number field, and $\phi(R)$ is a subring of $\mathcal{O}_{K_\phi}$ of finite index (an* order*). For $\sigma \in G_\mathbb{Q}$, $\sigma \circ \phi$ is again such a homomorphism (a* Galois conjugate*). For the eigencharacter $\phi_f\colon \mathbb{T} \to \mathbb{C}$, $T_n \mapsto a_n(f)$, of a newform f of weight 2 on $\Gamma_0(N)$: the* coefficient field $K_f = \mathbb{Q}(a_n(f) : n \geq 1)$ *is a number field, every $a_n(f)$ lies in $\mathcal{O}_{K_f}$, and (stated; Chapter 13) the conjugates $f^\sigma = \sum \sigma(a_n)q^n$ are newforms and K_f is totally real. For $f = f_E$, $K_f = \mathbb{Q}$, $\mathcal{O} = \mathbb{Z}$, and the only prime above ℓ is $\lambda = \ell$.*

Proof. $\phi(R)$ is a subring of $\mathbb{C}$ that is finitely generated as a $\mathbb{Z}$-module, so each of its elements is integral over $\mathbb{Z}$ (Proposition 6.3(iii), whose proof works in any field). The field K_ϕ is generated by the images of finitely many $\mathbb{Z}$-module generators, each algebraic, so it is a number field, and $\phi(R) \subseteq \mathcal{O}_{K_\phi}$. The $\mathbb{Q}$-span of $\phi(R)$ is a subring of $\mathbb{C}$ of finite dimension over $\mathbb{Q}$, a domain, hence a field, so it is K_ϕ; thus $\phi(R)$ and $\mathcal{O}_{K_\phi}$ are free abelian groups of the same rank $[K_\phi : \mathbb{Q}]$ (Theorem 6.6), and the index is finite. For $\sigma \in G_\mathbb{Q}$, $\sigma \circ \phi$ is a ring homomorphism. For ϕ_f, $\mathbb{T}$ is finitely generated as a $\mathbb{Z}$-module (Chapter 13), $\phi_f(\mathbb{T}) = \mathbb{Z}[a_n(f) : n \geq 1]$, which spans K_f, and $a_1(f) = 1$. □

Proposition 6.67 (primes above ℓ and reduction modulo λ)**.** *Let K be a number field, $\mathcal{O} = \mathcal{O}_K$ and ℓ a prime.*

(i) The primes $\lambda \mid \ell$ of $\mathcal{O}$ are the maximal ideals containing ℓ; there are at most $[K : \mathbb{Q}]$ of them; $k_\lambda = \mathcal{O}/\lambda \simeq \mathbb{F}_{\ell^f}$ with $f = f(\lambda \mid \ell)$; reduction modulo λ is the ring homomorphism $\mathcal{O} \to k_\lambda$, $a \mapsto \bar{a}$.

(ii) For $a, b \in \mathbb{Z}$: $a \equiv b \pmod{\lambda}$ iff $a \equiv b \pmod{\ell}$. For $a \in \mathcal{O}$: $\ell \mid N_{K/\mathbb{Q}}(a)$ iff some $\lambda \mid \ell$ contains a; and a lies in every $\lambda \mid \ell$ iff a lies in the radical of $\ell\mathcal{O}$, iff $a^m \in \ell\mathcal{O}$ for some $m \geq 1$.

(iii) (Enlarging.) If $K \subseteq K'$ then $\lambda\mathcal{O}_{K'} \neq \mathcal{O}_{K'}$, every prime λ' of $\mathcal{O}_{K'}$ dividing $\lambda\mathcal{O}_{K'}$ has $\lambda' \cap \mathcal{O} = \lambda$, and reduction modulo λ' restricts on $\mathcal{O}$ to reduction modulo λ followed by $k_\lambda \subseteq k_{\lambda'}$.

(iv) (Lying over, for orders.) Let α be integral over $\mathcal{O}$ and $\mathcal{O}' = \mathcal{O}[\alpha]$. For every prime λ of $\mathcal{O}$ there is a maximal ideal $\mathfrak{q}$ of $\mathcal{O}'$ with $\mathfrak{q} \cap \mathcal{O} = \lambda$, namely $\mathfrak{q} = \lambda' \cap \mathcal{O}'$ for a prime λ' above λ in the ring of integers of $K(\alpha)$; its residue field is a finite field containing k_λ.

(v) *(The step of Lemma lem:old.) Let $p \neq \ell$ be a prime, $a \in \mathcal{O}$, and α_p, β_p the roots of $X^2 - aX + p$; let λ' be a prime of the ring of integers of $K(\alpha_p)$ above λ. If $X^2 - aX + p \equiv (X-u)(X-w) \pmod{\lambda}$ with $u, w \in \mathcal{O}$, then $\alpha_p \equiv u$ or $\alpha_p \equiv w \pmod{\lambda'}$, and β_p is congruent to the other one. In particular, if $u = sp$ and $w = s$ with $s = \pm 1$, one of α_p, β_p is congruent to s modulo λ'.*

Proof. (i) A prime containing ℓ is nonzero, hence maximal; it lies above ℓ (Theorem 6.19), and there are at most $\sum e_i f_i = [K:\mathbb{Q}]$ of them. k_λ is a finite field of characteristic ℓ (Proposition 6.14(iii)). (ii) $\lambda \cap \mathbb{Z} = \ell\mathbb{Z}$. $N_{K/\mathbb{Q}}(a\mathcal{O}) = \prod_{\mathfrak{p}} N\mathfrak{p}^{v_{\mathfrak{p}}(a)}$ (Proposition 6.14), divisible by ℓ iff some $\mathfrak{p} \mid \ell$ has $v_{\mathfrak{p}}(a) > 0$. The intersection of the $\lambda \mid \ell$ is $\prod_{\lambda|\ell} \lambda$ (Proposition 6.15(i)), and a lies in it iff $v_\lambda(a) \geq 1$ for all $\lambda \mid \ell$ iff some power of a lies in $\ell\mathcal{O} = \prod \lambda^{e_\lambda}$. (iii) Theorem 6.19 for K'/K and $\mathfrak{p} = \lambda$. (iv) Let $K'' = K(\alpha)$ and λ' a prime of $\mathcal{O}_{K''}$ above λ, which exists by (iii). Then $\mathfrak{q} = \lambda' \cap \mathcal{O}'$ is a prime ideal of $\mathcal{O}' \subseteq \mathcal{O}_{K''}$ with $\mathfrak{q} \cap \mathcal{O} = \lambda$, and $\mathcal{O}'/\mathfrak{q}$ embeds in the finite field $\mathcal{O}_{K''}/\lambda'$, so it is a finite domain, hence a field. (v) α_p, β_p are integral over $\mathcal{O}$, so they lie in the ring of integers of $K(\alpha_p)$, whose quotient by λ' is a field k. In $k[X]$, $(X - \bar{\alpha}_p)(X - \bar{\beta}_p) = X^2 - \bar{a}X + \bar{p} = (X - \bar{u})(X - \bar{w})$, and unique factorisation in $k[X]$ gives $\{\bar{\alpha}_p, \bar{\beta}_p\} = \{\bar{u}, \bar{w}\}$ as multisets. □

Proposition 6.68 (maximal ideals from congruences)**.** *Let R be a commutative ring, finitely generated as a $\mathbb{Z}$-module, $\mathcal{O} = \mathcal{O}_K$, $\lambda \mid \ell$ a prime of $\mathcal{O}$, and $\phi\colon R \to \mathcal{O}$ a ring homomorphism.*

(i) $\mathfrak{m} = \ker(R \xrightarrow{\phi} \mathcal{O} \to k_\lambda)$ is a maximal ideal of R, and $R/\mathfrak{m}$ is a subfield of k_λ, of characteristic ℓ.

(ii) If $\phi'\colon R \to \mathcal{O}$ is another ring homomorphism with $\phi'(t) \equiv \phi(t) \pmod{\lambda}$ for all t in a set of ring generators of R (for $R = \mathbb{T}$: $a_n(g) \equiv a_n(f)$ for all n), then ϕ and ϕ' define the same $\mathfrak{m}$.

(iii) If $J \subseteq R$ is an ideal contained in $\mathfrak{m}$ such that R/J is a cyclic group of order r, then $\ell \mid r$ (with $\ell \mid 0$).

(iv) (Stated; Chapter 3.) $R \otimes \mathbb{Z}_\ell$ is the product of its localisations at its maximal ideals, which are the maximal ideals of R containing ℓ; and ϕ extends to $R \otimes \mathbb{Z}_\ell \to \mathcal{O}_\lambda$ (Proposition 6.69), which factors through the factor $(R \otimes \mathbb{Z}_\ell)_{\mathfrak{m}}$.

Proof. (i) $R/\mathfrak{m}$ embeds in the finite field k_λ; a subring of a finite field is a finite domain, hence a field. (ii) The two compositions $R \to k_\lambda$ are ring homomorphisms agreeing on generators, hence equal, so they have the same kernel. (iii) $R/\mathfrak{m}$ is a nonzero quotient of the cyclic group $R/J \simeq \mathbb{Z}/r$, so it is $\mathbb{Z}/s$ with $s \mid r$; it has characteristic ℓ, so $s = \ell$. (iv) We do not prove this here; the decomposition is the idempotent-lifting theorem of Chapter 3, and the extension of ϕ is $\phi \otimes \mathbb{Z}_\ell$ followed by the projection of $\mathcal{O} \otimes \mathbb{Z}_\ell$ onto its factor $\mathcal{O}_\lambda$ (Proposition 6.69), which kills the idempotents of the other factors of $R \otimes \mathbb{Z}_\ell$. □

Proposition 6.69 ($\mathcal{O}_K \otimes \mathbb{Z}_\ell$)**.** *For a number field K and a prime ℓ,*

$$\mathcal{O}_K \otimes_{\mathbb{Z}} \mathbb{Z}_\ell \simeq \prod_{\lambda|\ell} \mathcal{O}_{K,\lambda}, \qquad K \otimes_{\mathbb{Q}} \mathbb{Q}_\ell \simeq \prod_{\lambda|\ell} K_\lambda,$$

where $\mathcal{O}_{K,\lambda} = \varprojlim_k \mathcal{O}_K/\lambda^k$ is the λ-adic completion, a complete discrete valuation ring, free over $\mathbb{Z}_\ell$ of rank $e_\lambda f_\lambda$ ($\sum_\lambda e_\lambda f_\lambda = [K:\mathbb{Q}]$), with uniformiser any $\varpi \in \lambda \setminus \lambda^2$ and residue field k_λ; and K_λ, its fraction field, is an extension of $\mathbb{Q}_\ell$ of degree $e_\lambda f_\lambda$. The cases $K = \mathbb{Q}(\zeta_3)$ and $\mathbb{Q}(i)$ are Proposition 6.43.

Reference. We do not prove this here; it is proved in Chapter 7, and see [142, Chapter II, Section 8] or [174, Chapter II]. The algebraic core is the Chinese remainder theorem: $\mathcal{O}_K/\ell^k\mathcal{O}_K \simeq \prod_{\lambda\mid\ell}\mathcal{O}_K/\lambda^{ke_\lambda}$ for every k (Proposition 6.15), and $\mathcal{O}_K\otimes\mathbb{Z}_\ell = \varprojlim_k \mathcal{O}_K/\ell^k\mathcal{O}_K$ because $\mathcal{O}_K$ is free of finite rank over $\mathbb{Z}$. □

Example 6.70 (level 23)**.** The space $S_2(\Gamma_0(23))$ is two-dimensional and spanned by a newform f and its Galois conjugate (stated; PARI's `mfinit([23,2],0)`, and LMFDB 23.2.a.a). Its coefficient field is $K_f=\mathbb{Q}(\sqrt{5})$, and $a_2(f)$ is a root θ of X^2+X-1, the characteristic polynomial of T_2 (computed with PARI's `mfheckemat`); the first coefficients are

$$f = q+\theta q^2+(-2\theta-1)q^3+(-\theta-1)q^4+2\theta q^5+(\theta-2)q^6+(2\theta+2)q^7+\cdots, \qquad \theta^2+\theta-1=0,$$

and $a_{11}=-2\theta-4$, $a_{13}=3$ (PARI's `mfeigenbasis`). The ring of integers is $\mathcal{O}_{K_f}=\mathbb{Z}[\frac{1+\sqrt{5}}{2}]=\mathbb{Z}[\theta]$, as $\operatorname{disc}(X^2+X-1)=5$ is squarefree. Primes: $5=(\sqrt{5})^2$ is ramified, with $\theta\equiv 2 \pmod{\sqrt{5}}$ since $X^2+X-1\equiv(X-2)^2 \pmod 5$; 11 splits ($(\frac{5}{11})=1$) into $\lambda=(11,\theta-3)$ and $\lambda'=(11,\theta-7)$, as $X^2+X-1\equiv(X-3)(X-7) \pmod{11}$, both with residue field $\mathbb{F}_{11}$; 2 is inert ($5\equiv 5 \pmod 8$), with residue field $\mathbb{F}_4$, in which θ reduces to a root of X^2+X+1, a primitive cube root of unity. So the reductions of f modulo λ and λ' are different: modulo λ, $(a_2,a_3,a_5,a_7)\equiv(3,4,6,8)$, and modulo λ', $(7,7,3,5)$; they are exchanged by $\mathrm{Gal}(K_f/\mathbb{Q})$. A congruence "$a_n(g)\equiv a_n(f) \pmod\lambda$" as in Lemma lem:crit depends on λ, not only on ℓ. The Hecke algebra of level 23 is $\mathbb{T}=\mathbb{Z}[T_2]\simeq\mathbb{Z}[\theta]$. Indeed, let $\mathbb{T}$ be the subring of $\mathrm{End}(S_2(\Gamma_0(23)))$ generated by all the T_n, and $\phi_f\colon\mathbb{T}\to\mathcal{O}_{K_f}$ the eigencharacter of f (Proposition 6.66). It is injective: if $\phi_f(t)=0$, then also $\phi_{f^\sigma}(t)=\sigma(\phi_f(t))=0$ for the conjugate f^σ, so t kills f and f^σ, which span $S_2(\Gamma_0(23))$, and $t=0$. Its image is a subring of $\mathcal{O}_{K_f}=\mathbb{Z}[\theta]$ containing $\phi_f(T_2)=a_2(f)=\theta$, so it is $\mathbb{Z}[\theta]$, and $\mathbb{T}=\mathbb{Z}[T_2]$ since $\phi_f(T_2)$ generates the image. (Checked with PARI: `mfdim([23,2],1)` is 2 and `nfbasis(x^2+x-1)` is $[1,x]$, so $\mathbb{Z}[\theta]$ is the full ring of integers of $\mathbb{Q}(\sqrt{5})$.)

In the paper 6.71. Lemma lem:crit: "an eigenform g ... with coefficients in the ring of integers $\mathcal{O}$ of a number field, and a prime $\lambda\mid\ell$ of $\mathcal{O}$ such that $a_n(g)\equiv a_n(f) \pmod\lambda$ for every $n\geq 1$"; then "$I+J$ lies in the kernel of $\mathbb{T}\to\mathcal{O}/\lambda$, a maximal ideal of residue characteristic ℓ, and ℓ divides $\#\mathbb{T}/(I+J)=r$". The ring $\mathcal{O}$ exists by Proposition 6.66 (the eigencharacter ϕ_g of g takes values in a number field and in its ring of integers); $\phi_g\equiv\phi_f \pmod\lambda$ on the generators T_n gives the same kernel $\mathfrak{m}$ (Proposition 6.68(ii)), so $I=\ker\phi_f\subseteq\mathfrak{m}$ and $J\subseteq\ker\phi_g\subseteq\mathfrak{m}$; and $\ell\mid r$ is Proposition 6.68(iii) applied to $I+J$. "The same statements hold with $\mathbb{Z}$ replaced by $\mathbb{Z}_\ell$" uses Proposition 6.68(iv). Lemma lem:old: "after enlarging $\mathcal{O}$ and λ" is Proposition 6.67(iii): the eigenform g built from h has coefficients $\mu_p\in\{\alpha_p,\beta_p\}$ in a larger field, and a prime above λ there restricts to λ; "one of α_p,β_p is congruent to $a_p(f)$ modulo a prime above λ in $\mathcal{O}[\alpha_p]$" is Proposition 6.67(iv) and (v), with $X^2-a_p(h)X+p\equiv(X-a_p(f)p)(X-a_p(f)) \pmod\lambda$ and $a_p(f)=\pm1$. In Section 3 of the paper all forms have rational coefficients and $\lambda=\ell$; Lemma lem:old is needed for general h, whose coefficient field can be larger, as in Example 6.70.

6.8 Exercises

Exercise 6.72. Let $K=\mathbb{Q}(\sqrt{13})$. Show that $\mathcal{O}_K=\mathbb{Z}[\theta_{13}]$ with $\theta_{13}=\frac{1+\sqrt{13}}{2}$, that $d_K=13$, and that $\frac{3+\sqrt{13}}{2}$ is a unit of norm -1. Factor 2, 3 and 13 in $\mathcal{O}_K$ (answer: 2 inert, 3 split, 13 ramified). Show that Dedekind-Kummer applied to the generator $\sqrt{13}$ (that is, to $\mathbb{Z}[\sqrt{13}]$) at $p=2$ would predict that 2 ramifies, and explain why the theorem does not apply there.

Exercise 6.73. In the non-integrally closed ring $A=\mathbb{Z}[\sqrt{-3}]$ let $\mathfrak{a}=(2,1+\sqrt{-3})$. Show that $\mathfrak{a}^2=2\mathfrak{a}$ but $\mathfrak{a}\neq(2)$, so ideals cannot be cancelled in A; deduce that A is not a Dedekind domain and identify the hypothesis of Definition 6.10 that fails. What is $\mathfrak{a}\mathbb{Z}[\zeta_3]$?

Exercise 6.74. Factor 65, 91 and $1729=7\cdot13\cdot19$ into primes in $\mathbb{Z}[i]$ and in $\mathbb{Z}[\zeta_3]$. Deduce the number of ways of writing 65 as a^2+b^2 with $0<a<b$, and explain the answer by counting the elements of norm 65 in $\mathbb{Z}[i]$.

Exercise 6.75. Show that a prime $p\neq2,5$ splits in $\mathbb{Q}(\sqrt{-5})$ iff $p\equiv1,3,7,9 \pmod{20}$. Show that the primes above 3 and 7 are not principal, that the primes above 3 lie in the class of $\mathfrak{p}_2$ of Example 6.18, and, using Theorem 6.16, that $h(\mathbb{Q}(\sqrt{-5}))=2$. Which primes p are of the form a^2+5b^2?

Exercise 6.76. Let $L=\mathbb{Q}(2^{1/3},\zeta_3)$, with $\mathrm{Gal}(L/\mathbb{Q})\simeq S_3$ acting on the three cube roots of 2. For $p\geq5$, show using Corollary 6.29: if $p\equiv2 \pmod 3$, Frob_p is a transposition and X^3-2 has exactly one root modulo p; if $p\equiv1 \pmod 3$, Frob_p is trivial or a 3-cycle according as 2 is or is not a cube modulo p. Determine Frob_p for $p=5,7,31$, and deduce from Theorem 6.60 that 2 is a cube modulo p for a set of primes of density $\frac{2}{3}$.

Exercise 6.77. Without using Theorem 6.22, show that an odd prime p ramifies in $\mathbb{Q}(\sqrt{d})$ (d squarefree) iff $p\mid d$: compute $(p,\sqrt{d})^2$ when $p\mid d$, and when $p\nmid d$ show that $\mathcal{O}_K/p\mathcal{O}_K$ is reduced.

Exercise 6.78. Factor 2, 13 and 29 in $\mathbb{Z}[\zeta_7]$ and check $efg=6$ against Theorem 6.49. The quadratic subfield of $\mathbb{Q}(\zeta_7)$ is $\mathbb{Q}(\sqrt{-7})$; check that the splitting of each of these primes in it agrees with $(\frac{p}{7})$ and with the image of $\mathrm{Frob}_p=\sigma_p$ in $(\mathbb{Z}/7)^\times/(\mathbb{Z}/7)^{\times2}$.

Exercise 6.79. Determine the decomposition and inertia groups in $\mathrm{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q})\simeq(\mathbb{Z}/8)^\times$ of 2, 3, 5, 7 and 17. Identify the three quadratic subfields $\mathbb{Q}(i)$, $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{-2})$ with the subgroups $\{1,5\}$, $\{1,7\}$, $\{1,3\}$, and deduce that $(\frac{-2}{p})=1$ iff $p\equiv1,3 \pmod 8$.

Exercise 6.80. (a) List the quadratic fields unramified outside $\{3,7\}$ (answer: $\mathbb{Q}(\sqrt{-3})$, $\mathbb{Q}(\sqrt{-7})$, $\mathbb{Q}(\sqrt{21})$). Which of them is cut out by χ_S for $S=\{3,7\}$, and what is its conductor? (b) List the seven quadratic fields unramified outside $\{2,3\}$, with their discriminants.

Exercise 6.81. In $\mathbb{Z}_3[\zeta_3]$ compute v_π of $1+\zeta_3$, $2+\zeta_3$, 3, $\sqrt{-3}$, $1-\zeta_3^2$ and $4+\zeta_3$ (answers $0,1,2,1,1,0$). Show that the unit group of $\mathbb{Z}_3[\zeta_3]/(\pi^2)$ is cyclic of order 6, generated by the class of $-\zeta_3$, and that every unit of $\mathbb{Z}_3[\zeta_3]$ is $\pm\zeta_3^k$ times a unit congruent to 1 modulo π^2.

Exercise 6.82. Let $\sigma=\left(\begin{smallmatrix}1&-3\\1&-2\end{smallmatrix}\right)\in\mathrm{GL}_2(\mathbb{Z}_3)$, acting on $T=\mathbb{Z}_3^2$. Check that σ has order 3 and determinant 1, that its reduction modulo 3 is a nontrivial unipotent, and that e_1 generates T over $\mathbb{Z}_3[\sigma]$. Show more generally that $v\in T$ generates T over $\mathbb{Z}_3[\sigma]$ iff $v\notin(1-\sigma)T$, and find $(1-\sigma)T$ and the fixed line of σ on $T/3T$ explicitly.

Exercise 6.83. Describe $\mathbb{Z}_\ell[\zeta_3]$ for $\ell=2,5,7$. For $\ell=7$, find the roots of X^2+X+1 modulo 7 and modulo 49 (answers $2,4$ and $30,18$), and show that the idempotents of $\mathbb{Z}_7[\zeta_3]\simeq\mathbb{Z}_7\times\mathbb{Z}_7$ are congruent modulo 49 to $4\zeta_3+27$ and $45\zeta_3+23$.

Exercise 6.84. (a) Let σ have characteristic polynomial X^2+X+1 and let $g=-\sigma$ (order 6, types II, II*). Show that the commutant of g and its trace-zero line are those of σ, and that $AgA^{-1}=g^q$ for an odd prime $q\neq3$ gives the same sign $\chi_{-3}(q)$ as in Proposition 6.45(iii). (b) Using the table of Section 1 of the paper, compute $e_\ell(E,q)$ for $q\in\{5,7,11,13\}$, every odd $\ell\neq q$, and the types IV and III. Show that $e_3(E,q)\geq1$ for every $q\geq5$ of type II, II*, IV, IV*, and decide for which q the same holds for type III.

Exercise 6.85. Let E have nonsplit multiplicative reduction at $q \neq \ell$, with $\rho(\mathrm{Frob}) = \left(\begin{smallmatrix} -q & c' \\ 0 & -1 \end{smallmatrix}\right)$ for an arithmetic Frobenius. Show that the arithmetic Frobenius acts on $(\mathrm{ad}^0 V)^{I_q}$ by q and on $(\mathrm{ad}^0 V(1))^{I_q}$ by q^2, and the geometric one by q^{-1} and q^{-2}. Deduce that $\det(1 - \mathrm{Frob}_q^{-1} \mid (\mathrm{ad}^0 V(1))^{I_q}) = 1 - q^{-2} = L_q(\mathrm{ad}^0 V, 1)^{-1}$, whereas the arithmetic Frobenius gives $1 - q^2$: a different number with the same ℓ-adic valuation.

Exercise 6.86. Let $E\colon y^2 = x^3 - x$. Show that $a_p = 0$ for every prime $p \equiv 3 \pmod 4$, using the substitution $x \mapsto -x$ and $(\frac{-1}{p}) = -1$. Compute $a_5 = -2$, $a_{13} = 6$ and $a_{17} = 2$ by counting points, and check that $p = (a_p/2)^2 + b^2$ with $b \in \mathbb{Z}$ for $p = 5, 13, 17$ and 29 ($a_{29} = -10$). Relate the first statement to Theorem 6.63(ii), and the second to the factorisation $p = \varpi\bar{\varpi}$ in $\mathbb{Z}[i]$ with $a_p = \varpi + \bar{\varpi}$ for a suitable prime ϖ above p (stated; Chapter 9).

Exercise 6.87. (a) For 11a1, $a_2 = -2$. Using Proposition 6.62 ((a)⇒(b) needs no semisimplicity), show that $\bar{\rho}_{E,3} \not\cong \bar{\rho}_{E,3} \otimes \chi_{-3}$. (b) For $E\colon y^2 = x^3 - 6x - 8$, compute a_5, a_{11}, a_{17} (answers 3, 3, -6) and explain, using Proposition 6.62 and Chapter 5, why $3 \mid a_p$ for every prime $p \equiv 2 \pmod 3$ of good reduction.

Exercise 6.88. Let f be the newform of level 23 of Example 6.70, with coefficients $a_n = x_n + y_n\theta$, $x_n, y_n \in \mathbb{Z}$, and f^σ its conjugate. Show that $a_n(f) \equiv a_n(f^\sigma) \pmod{\sqrt{5}}$ for all n, and that $(\sqrt{5})$ is the only prime of $\mathcal{O}_{K_f}$ modulo which all coefficients of f and f^σ agree. Compute the reduction of f modulo the prime above 2 up to q^7, in $\mathbb{F}_4$.

Exercise 6.89. Let $K = \mathbb{Q}(\sqrt{5})$ and $K' = \mathbb{Q}(\sqrt{5}, i)$. Determine e, f, g for 2, 3 and 5 in K and in K' (answers in K': $(2,2,1)$, $(1,2,2)$, $(2,1,2)$), and describe, for each prime λ of K above these, the primes λ' of K' above it and the inclusions $k_\lambda \subseteq k_{\lambda'}$ of Proposition 6.67(iii).

Exercise 6.90. Show that $\mathbb{Z}[\frac{1+\sqrt{5}}{2}]^\times = \{\pm u^k : k \in \mathbb{Z}\}$ with $u = \frac{1+\sqrt{5}}{2}$, by the method of Theorem 6.9(iii). Show that the reduction of u modulo the prime above 2 has order 3 in $\mathbb{F}_4^\times$ and modulo each prime above 11 has order dividing 10; which orders occur?

6.9 Notes and references

The algebraic number theory of Sections 6.1 to 6.3 follows Neukirch [142], Chapter I (Sections 2 to 3 for integrality, integral bases and Dedekind domains, Sections 8 and 9 for the splitting of primes, decomposition and inertia groups, Section 10 for cyclotomic fields), and Marcus [123], Chapters 2 to 4, which is the gentlest complete treatment and has many exercises of the kind given here. The proof of unique factorisation of ideals (Lemma 6.12, Theorem 6.13) is Neukirch's; the proof of transitivity in Proposition 6.23 and of the surjectivity onto the residue Galois group in Theorem 6.24 are the standard ones (Marcus, Chapter 4). Atiyah and Macdonald [7], Chapters 5 and 9, treat integral extensions, lying over and Dedekind domains in the language of commutative algebra. Lang [108] is a further reference for the Dedekind zeta function and densities (Chapter VIII). Minkowski's theorem, Dirichlet's unit theorem, the analytic continuation of ζ_K and Chebotarev's theorem are stated, with references to Neukirch, Chapter I, Sections 5 to 7, and Chapter VII, Sections 5 and 13.

The splitting of primes in quadratic fields and the Gaussian and Eisenstein integers are in Ireland and Rosen [87], Chapters 1 and 9 and Chapter 13, and in Cox [34], Sections 5 and 7, where prime discriminants (Proposition 6.36) are also discussed. Cyclotomic fields, the discriminant formula, Kronecker-Weber and the dictionary between Dirichlet characters and characters of $G_{\mathbb{Q}}$

follow Washington [201], Chapters 2, 3 and 14. The tame relation (Proposition 6.31) is in Serre [174], Chapter IV, Sections 1 and 2, where the higher ramification groups are defined; Chapter 7 gives the local version. Frobenius elements in $G_{\mathbb{Q}}$ and their use for ℓ-adic representations are in Serre [178], Chapter I. Class field theory in idelic form, with its two sign conventions, is in Neukirch, Chapter VI, and in Milne's notes [133].

For complex multiplication, Theorem 6.63 quotes Silverman [184], Chapter II and Appendix A (the thirteen rational j-invariants), and Cox [34], Sections 7 to 14 (class number one and Deuring's reduction criterion); the open image theorem is Serre [171], and the density zero of $\{p : a_p(E) = 0\}$ for E without complex multiplication is Serre [175]. The argument that a prime ramified in the CM field divides the conductor (Theorem 6.63(iii)) is the elementary one given here; it can also be read off the conductor of an induced representation.

All theorem, section and chapter numbers of books cited in this chapter (Neukirch, Marcus, Washington, Ireland-Rosen, Cox, Serre, Lang, Silverman) are recalled and were not checked against printed copies; they should be read as pointers, and no proof in the book depends on them. Every numerical example (class numbers, discriminants, factorisations of primes, Frobenius classes, the coefficients of the level 23 newform, the traces of Frobenius of the curves of Example 6.64 and Exercise 6.87) was checked with PARI/GP [148], for instance with the following commands.

```
quadclassunit(-20)[1]                        \\ class number 2

Chapter 7

Local fields

The paper works at a bad prime $q \neq \ell$ with the restriction of $\rho = \rho_{E,\ell}$ to a decomposition group $G_{\mathbb{Q}_q}$, and every local statement it makes rests on a small amount of local field theory: the fields $\mathbb{Q}_q$, $\mathbb{Q}_q^{\mathrm{ur}}$ and $\mathbb{Z}_\ell$; Hensel's lemma and ℓ-th powers; the inertia group, its wild part and its tame quotient; the tame relation Frob t Frob$^{-1} = t^q$; the Kummer cocycle of the Tate parameter on inertia and on Frobenius; quadratic characters locally; Grothendieck's monodromy theorem and Weil-Deligne representations; and the inertia invariants, local L-factors and conductors of the representations that occur at a bad prime, together with those of their adjoints. This chapter supplies all of it, with complete proofs except for local class field theory, the identification of Kummer classes with Galois cohomology (proved in Chapter 17), the integrality of the Swan conductor, upper numbering, epsilon factors and a few classification statements, which are stated with references. It uses Chapter 1 for profinite groups, Chapter 2 for v_p, $|\cdot|_p$, finite fields and powers in $\mathbb{F}_q^\times$, Chapter 3 for discrete valuation rings and the algebraic $\mathbb{Z}_\ell$, Chapter 4 for the linear algebra of inertia actions, Chapter 5 for infinite Galois theory and Kummer theory, and Chapter 6 for number fields, decomposition groups and quadratic characters. Elliptic curves appear only in examples and in quoted statements from Chapters 10 and 11.

Core results at a glance

Throughout, K is $\mathbb{Q}_p$ or a finite extension, with $\mathcal{O}_K$, $\mathfrak{m}_K$, uniformiser ϖ, residue field $\mathbb{F}_q$; $\ell \neq p$; Frob is an arithmetic and $\Phi = \mathrm{Frob}^{-1}$ a geometric Frobenius; $I_K \supseteq P_K$ are the inertia and wild inertia groups; $\|w\| = q^{d(w)}$ on the Weil group.

7.1 Conventions. K, $\mathcal{O}_K$, ϖ_K, $k_K = \mathbb{F}_q$, v_K, $|\cdot|_K = q^{-v_K}$; q is both $\#k_K$ and the paper's bad prime; $K^{\mathrm{ur}} \subseteq K^{\mathrm{tame}}$, I_K, P_K; $\mathbb{Z}_\ell(1) = \varprojlim \mu_{\ell^k}$ and t_ζ; ε unramified of order ≤ 2, θ_m, η_{ur}, $[a]$, N, χ_d by discriminant. Convention 7.1.

7.2 Absolute values (definition): nonarchimedean, equivalent, discrete; valuation ring, maximal ideal, residue field. Definition 7.2.

7.3 Basic properties. Nonarchimedean iff $|n| \leq 1$ on $\mathbb{Z}$; isosceles triangles; $\mathcal{O}$ local with $\mathcal{O}^\times = \{|x| = 1\}$; balls are open and closed; $\sum a_n$ converges iff $a_n \to 0$ (complete case); discrete implies $|x| = c^{v(x)}$ with $\mathcal{O}$ a discrete valuation ring; equivalence iff $|\cdot|_1 = |\cdot|_2^s$. *(proved here)* Proposition 7.3.

7.4 Unconditional summation. In a complete nonarchimedean field a countable family with only finitely many terms above each $\delta > 0$ can be summed in any order and grouping. *(proved here)* Lemma 7.4.

7.5 Completion. Exists, unique up to unique isometry; the value group and the rings $\mathcal{O}/\varpi^n$ do not change; $\hat{\mathcal{O}} \simeq \varprojlim \mathcal{O}/\varpi^n$ topologically. *(proved here)* Theorem 7.6.

7.6 $\mathbb{Q}_p$ and $\mathbb{Z}_p$ (definition): completion of $\mathbb{Q}$ for $|\cdot|_p$, and its valuation ring. Definition 7.7.

7.7 Structure of $\mathbb{Z}_p$. $\mathbb{Z}_p$ is the closure of $\mathbb{Z}$, a complete discrete valuation ring with residue field $\mathbb{F}_p$; $\mathbb{Z}_p \simeq \varprojlim \mathbb{Z}/p^n$ as topological rings (so it is the algebraic $\mathbb{Z}_\ell$ of Chapter 3); $\mathbb{Q}_p^\times = p^{\mathbb{Z}} \times \mathbb{Z}_p^\times$; $\mathbb{Z}_p$ compact, $\mathbb{Q}_p$ locally compact and totally disconnected; $q^{-1} \in \mathbb{Z}_p$ for primes $q \neq p$. *(proved here)* Theorem 7.8.

7.8 p-adic expansions. $x = \sum_{i \geq v} a_i p^i$ uniquely, $a_i \in \{0, \dots, p-1\}$; partial sums are the residues; $x \in \mathbb{Q}$ iff the digits are eventually periodic. *(proved here)* Proposition 7.10.

7.9 Hensel's lemma. If $|f(a_0)| < |f'(a_0)|^2$, Newton's iteration converges to the unique root a with $|a - a_0| < |f'(a_0)|$, and $|a - a_0| = |f(a_0)/f'(a_0)|$; a simple root modulo $\mathfrak{m}$ lifts uniquely. *(proved here)* Theorem 7.12.

7.10 Hensel, factorisation form. Over a complete discrete valuation ring, $\bar{f} = \bar{g}\bar{h}$ with $\bar{g}$ monic and $\bar{g}, \bar{h}$ coprime lifts to $f = gh$, g monic of degree $\deg \bar{g}$. *(proved here)* Theorem 7.14.

7.11 Coefficients of irreducible polynomials. If $f = \sum a_i X^i \in K[X]$ is irreducible with $a_0 a_n \neq 0$, $\max|a_i| = \max(|a_0|, |a_n|)$; a monic irreducible polynomial with $f(0) \in \mathcal{O}$ lies in $\mathcal{O}[X]$. *(proved here)* Corollary 7.15.

7.12 Teichmüller lifts. $[a] = \lim \tilde{a}^{q^n}$ is the unique lift of $a \in \mathbb{F}_q$ with $[a]^q = [a]$; $k^\times \simeq \mu_{q-1}(K)$; $\mathcal{O}^\times = \mu_{q-1}(K) \times (1 + \mathfrak{m})$. *(proved here)* Theorem 7.17.

7.13 Units. For p odd, exp and log give $p^n\mathbb{Z}_p \simeq 1 + p^n\mathbb{Z}_p$ $(n \geq 1)$, $1 + p\mathbb{Z}_p \simeq \mathbb{Z}_p$ generated by $1 + p$, and $\mathbb{Q}_p^\times \simeq \mathbb{Z} \times \mathbb{Z}/(p-1) \times \mathbb{Z}_p$; for $p = 2$, $\mathbb{Z}_2^\times = \{\pm 1\} \times (1 + 4\mathbb{Z}_2)$, $1 + 4\mathbb{Z}_2 \simeq \mathbb{Z}_2$ generated by 5; in general $K^\times = \varpi^{\mathbb{Z}} \times \mu_{q-1}(K) \times U^{(1)}$ with $U^{(1)}$ pro-p and uniquely m-divisible for $p \nmid m$. *(proved here)* Theorem 7.18.

7.14 Roots of unity. $\mu(\mathbb{Q}_p) = \mu_{p-1}$ (p odd), $\mu(\mathbb{Q}_2) = \{\pm 1\}$; $\mu_m(K) = \mu_{\gcd(m, q-1)}$ for $p \nmid m$; $\mu_{\ell^k} \subset \mathbb{Q}_p$ iff $\ell^k \mid p - 1$; $i \in \mathbb{Q}_\ell$ iff $\ell \equiv 1 \pmod 4$. *(proved here)* Corollary 7.19.

7.15 ℓ^k-th powers ($\ell \neq p$). A unit is an ℓ^k-th power iff its reduction is one in $\mathbb{F}_q^\times$; $\varpi^a u$ is one iff moreover $\ell^k \mid a$; $K^\times/(K^\times)^{\ell^k} \simeq \mathbb{Z}/\ell^k \times \mathbb{Z}/\ell^{\min(k, v_\ell(q-1))}$, of order $\ell^k \# \mu_{\ell^k}(K)$; $\varprojlim K^\times/(K^\times)^{\ell^k} \simeq \mathbb{Z}_\ell \times \mathbb{Z}/\ell^{v_\ell(q-1)}$ with torsion $\mathbb{F}_q^\times \otimes \mathbb{Z}_\ell$; square classes of $\mathbb{Q}_p$ and $\mathbb{Q}_2$. *(proved here)* Theorem 7.20.

7.16 Equivalence of norms. All norms on a finite-dimensional space over a complete field are equivalent, and the space is complete. *(proved here)* Lemma 7.23.

7.17 Extension of the absolute value. $|x|_L = |N_{L/K} x|^{1/[L:K]}$ is the unique extension; L is complete; $\mathcal{O}_L$ is the integral closure; conjugates have equal absolute values. *(proved here)* Theorem 7.24.

7.18 e **and** f**.** $\mathcal{O}_L$ is free over $\mathcal{O}_K$ with basis $\alpha_i \varpi_L^j$, and $ef = [L : K]$; multiplicative in towers. *(proved here)* Theorem 7.25.

7.19 Unramified, totally, tamely, wildly ramified (definition): $e = 1$, $f = 1$, $p \nmid e$, $p \mid e$. Definition 7.26.

7.20 Eisenstein. L/K is totally ramified of degree e iff it is generated by a root π of an Eisenstein polynomial of degree e; then π is a uniformiser and $\mathcal{O}_L = \mathcal{O}_K[\pi]$. *(proved here)* Theorem 7.27.

7.21 Examples; $\mathbb{Z}_3[\zeta_3]$**.** $\mathbb{Q}_p(\zeta_{p^n})$ is totally ramified with group $(\mathbb{Z}/p^n)^\times$; $\mathbb{Q}_3(\zeta_3) = \mathbb{Q}_3(\sqrt{-3})$ is tamely totally ramified with ring of integers $\mathbb{Z}_3[\zeta_3] = \mathbb{Z}_3 \otimes \mathbb{Z}[\zeta_3]$, uniformiser $1-\zeta_3$, $(1-\zeta_3)^2 = -3\zeta_3$, the completion of $\mathbb{Z}[\zeta_3]$; $\mathbb{Q}_p(p^{1/m})$, $\mathbb{Q}_p(\sqrt{p^*})$. *(proved here)* Proposition 7.28.

7.22 Completions of number fields. The extensions of $|\cdot|_p$ to F correspond to the $\mathfrak{p} \mid p$; $F_\mathfrak{p}$ has $e_\mathfrak{p}$, $f_\mathfrak{p}$ and $\mathcal{O}_{F_\mathfrak{p}} = \varprojlim \mathcal{O}_F/\mathfrak{p}^n$; $\mathcal{O}_F \otimes \mathbb{Z}_p \simeq \prod_{\mathfrak{p}|p} \mathcal{O}_{F_\mathfrak{p}}$. *(proved here)* Theorem 7.30.

7.23 Krasner's lemma. If $|\beta - \alpha| < |\alpha - \alpha_i|$ for the other conjugates, $K(\alpha) \subseteq K(\beta)$; nearby polynomials define the same fields. *(proved here)* Lemma 7.31.

7.24 Decomposition groups. $\mathrm{Gal}(L_\mathfrak{P}/F_\mathfrak{p}) \simeq D_\mathfrak{P}$ with inertia to inertia; an embedding $\overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_p$ identifies $G_{\mathbb{Q}_p}$ with $D_{\bar{\mathfrak{P}}} \subseteq G_\mathbb{Q}$, I_p with $I_{\bar{\mathfrak{P}}}$, Frobenius with Frobenius. *(proved here)* Proposition 7.32.

7.25 Tame totally ramified extensions. $L = K(\varpi^{1/e})$; Galois iff $e \mid q-1$, and then cyclic, $\sigma \mapsto \sigma(\alpha)/\alpha$. *(proved here)* Proposition 7.33.

7.26 Unramified extensions. Exactly one of each degree, $K_f = K(\mu_{q^f-1})$; $\mathrm{Gal}(K_f/K) \simeq \mathrm{Gal}(\mathbb{F}_{q^f}/\mathbb{F}_q)$, cyclic, generated by Frob; largest unramified subextension L_0 with L/L_0 totally ramified. *(proved here)* Theorem 7.34.

7.27 K^{ur} (definition): $\bigcup K_f = K(\mu_m : p \nmid m)$. Definition 7.35.

7.28 Properties of K^{ur}**.** $\mathrm{Gal}(K^{\mathrm{ur}}/K) \simeq \hat{\mathbb{Z}}$, generated by Frob; discrete, not complete; Hensel holds; units are m-th powers for $p \nmid m$, and x is an m-th power iff $m \mid v_K(x)$; $\mu_{\ell^\infty} \subset \mathbb{Q}_q^{\mathrm{ur}}$. *(proved here)* Proposition 7.36.

7.29 Frobenius convention. Frob arithmetic, $\Phi = \mathrm{Frob}^{-1}$ geometric; $\chi_\ell(\mathrm{Frob}) = q$; group theory uses Frob, L-factors use Φ. Convention 7.37.

7.30 Unramified base change. For $K/\mathbb{Q}_p$ unramified: $K^{\mathrm{ur}} = \mathbb{Q}_p^{\mathrm{ur}}$, $I_K = I_p$, $P_K = P_p$; images of inertia, invariants, monodromy and conductors are unchanged. In general $I_K = I_p \cap G_K$ has index $e(K/\mathbb{Q}_p)$. *(proved here)* Proposition 7.38.

7.31 The cyclotomic character locally. χ_ℓ is unramified at $p \neq \ell$ with $\chi_\ell(\mathrm{Frob}_p) = p$; $\chi_p(I_p) = \mathbb{Z}_p^\times$. *(proved here)* Proposition 7.39.

7.32 Ramification groups (definition): $G_i = \{\sigma : v_L(\sigma x - x) \geq i+1 \ \forall x \in \mathcal{O}_L\}$; G_0 inertia, G_1 wild inertia. Definition 7.41.

7.33 Structure of the G_i. $\#G_0 = e$; $G_0/G_1 \hookrightarrow k_L^\times$ by $\sigma \mapsto \sigma\pi/\pi$; $G_i/G_{i+1} \hookrightarrow (k_L, +)$ for $i \geq 1$; so G_1 is the Sylow p-subgroup of G_0, and L/K is tame iff $G_1 = 1$. Upper numbering, Herbrand and Hasse-Arf are stated. *(proved here, except (iv): stated; reference)* Proposition 7.42.

7.34 The filtration $G_K \supset I_K \supset P_K$. $G_K/I_K \simeq \hat{\mathbb{Z}}$; $K^{\mathrm{tame}} = \bigcup_{p\nmid m} K^{\mathrm{ur}}(\varpi^{1/m})$; $P_K = \mathrm{Gal}(\overline{\mathbb{Q}}_p/K^{\mathrm{tame}})$ is normal, pro-p, maps onto every $G_1(L/K)$, and is the unique pro-p Sylow subgroup of I_K. *(proved here, except the upper filtration (iv): stated; reference)* Theorem 7.45.

7.35 Semidirect product. $G_K = I_K \rtimes \overline{\langle \mathrm{Frob} \rangle}$ with $\overline{\langle \mathrm{Frob} \rangle} \simeq \hat{\mathbb{Z}}$; a Frobenius-invariant character of I_K extends to G_K. *(proved here)* Corollary 7.46.

7.36 The tame character. $\theta_m(\sigma) = \sigma(\varpi^{1/m})/\varpi^{1/m}$ is a surjection $I_K \to \mu_m$ independent of choices; $I_K/P_K \simeq \prod_{\ell\neq p} \mathbb{Z}_\ell(1)$, procyclic of order prime to p; $t_\ell\colon I_K \to \mathbb{Z}_\ell(1)$ identifies the maximal pro-ℓ quotient of I_K with $\mathbb{Z}_\ell(1)$; maps from I_K to pro-ℓ groups factor through t_ℓ; $t_{\ell,K}|_{I_L} = e(L/K)t_{\ell,L}$. *(proved here)* Theorem 7.47.

7.37 Open subgroups of inertia. Every open $U \subseteq I_K$ is I_L for a finite L/K; its maximal pro-ℓ quotient is $\mathbb{Z}_\ell(1)$. *(proved here)* Corollary 7.48.

7.38 A Frobenius fixing $\varpi^{1/m}$. Some arithmetic Frobenius lift fixes all $\varpi^{1/m}$, $p \nmid m$; two differ by P_K. *(proved here)* Corollary 7.49.

7.39 The tame relation. $t_\ell(\tau\sigma\tau^{-1}) = \chi_\ell(\tau)t_\ell(\sigma)$. On I_K/P_K one has $\mathrm{Frob}\, t\, \mathrm{Frob}^{-1} = t^q$, equivalently $\mathrm{Frob}^{-1}\, t\, \mathrm{Frob} = t^{q^{-1}}$, and for the geometric Frobenius $\Phi\, t\, \Phi^{-1} = t^{q^{-1}}$. The group $\mathrm{Gal}(K^{\mathrm{tame}}/K)$ is $\prod_{\ell\neq p} \mathbb{Z}_\ell(1) \rtimes \hat{\mathbb{Z}}$, with 1 acting by q. *(proved here; the presentation by two generators is stated; reference)* Theorem 7.50.

7.40 Finite tame images of inertia. If $\rho(I_K)$ is finite of order prime to p, it is cyclic and $\rho(\mathrm{Frob})h\rho(\mathrm{Frob})^{-1} = h^q$; Frobenius centralises (inverts) a generator of order m iff $q \equiv 1$ $(q \equiv -1) \pmod m$. *(proved here)* Corollary 7.52.

7.41 Wild inertia in ℓ-adic representations. $\rho(P_K)$ is a finite p-group embedding in $\mathrm{GL}_n(\mathcal{O}/\varpi_\lambda)$; on an open normal $I_1 \subseteq I_K$, ρ factors through t_ℓ; ρ is tame iff $\rho(I_K)$ has no element of order p. *(proved here)* Proposition 7.53.

7.42 Kummer theory over K. The Kummer cocycle κ_x and its properties; $K^\times/(K^\times)^{\ell^k} \simeq H^1(K, \mu_{\ell^k})$ and $\widehat{K^\times} \simeq H^1(K, \mathbb{Z}_\ell(1)) \simeq \mathbb{Z}_\ell \times \mathbb{Z}/\ell^{v_\ell(q-1)}$. *(proved here, except the isomorphisms with H^1: stated; Chapter 17)* Proposition 7.57.

7.43 The Kummer cocycle on inertia and Frobenius. $\kappa_x = v_K(x)\kappa_\varpi + \kappa_u$; $\kappa_x|_{I_K} = v_K(x)\, t_\ell$; κ_u is unramified with class the class of $\bar{u}$ in $\mathbb{F}_q^\times \otimes \mathbb{Z}_\ell$; $c' = \kappa_x(\mathrm{Frob})$ is defined modulo $(v_K(x), q-1)$; I_K fixes x^{1/ℓ^k} iff $\ell^k \mid v_K(x)$. *(proved here)* Theorem 7.58.

7.44 Quadratic extensions of $\mathbb{Q}_p$. Three for p odd (one unramified, two tame), restricting to the unique order-two character θ_2 of I_p when ramified; seven for $p = 2$, with $\mathbb{Q}_2(\sqrt{5}) = \mathbb{Q}_2(\sqrt{-3})$ unramified and jumps 1 for $\mathbb{Q}_2(\sqrt{-1})$, $\mathbb{Q}_2(\sqrt{3})$, 2 for $\mathbb{Q}_2(\sqrt{\pm 2})$, $\mathbb{Q}_2(\sqrt{\pm 10})$. *(proved here)* Proposition 7.60.

7.45 Global quadratic characters locally. χ_d is unramified at $p \nmid d$ with $\chi_d(\mathrm{Frob}_p) = (d/p)$; χ_{q^*} is unramified outside q and equals θ_2 on I_q; twisting by χ_{q^*} changes nothing on inertia at $p \neq q$; every quadratic character of $G_{\mathbb{Q}_p}$ is a restriction of a product of χ_d's. *(proved here)* Proposition 7.61.

7.46 Local class field theory for $\mathbb{Q}_p$. $\mathbb{Q}_p^{\mathrm{ab}} = \mathbb{Q}_p^{\mathrm{ur}}\mathbb{Q}_p(\mu_{p^\infty})$; the Artin map ($p \mapsto \mathrm{Frob}$, $u \mapsto (\zeta \mapsto \zeta^{u^{-1}})$); $a(\chi)$ is the least n with $\chi(\mathrm{Art}(U^{(n)})) = 1$. *(stated; reference)* Theorem 7.62.

7.47 Weil-Deligne relation. $\|w\| = q^{d(w)}$, $r(w)Nr(w)^{-1} = \|w\|N$: $r(\mathrm{Frob})Nr(\mathrm{Frob})^{-1} = qN$, $r(\Phi)Nr(\Phi)^{-1} = q^{-1}N$. Convention 7.64.

7.48 The Weil group (definition): $W_K = \{w \in G_K : w|_{K^{\mathrm{ur}}} \in \mathrm{Frob}^{\mathbb{Z}}\}$, with I_K open. Definition 7.65.

7.49 Properties of W_K. Dense in G_K, $W_K/I_K \simeq \mathbb{Z}$, $\|w\| = \chi_\ell(w)$; unramified characters are free on Φ; $W_{\mathbb{Q}_p}^{\mathrm{ab}} \simeq \mathbb{Q}_p^\times$ (stated). *(proved here, except (iv): stated; reference)* Proposition 7.66.

7.50 Matrix logarithm. exp and log are inverse bijections $\ell^2\,\mathrm{M}_n(\mathcal{O}) \leftrightarrows 1 + \ell^2\,\mathrm{M}_n(\mathcal{O})$, with $g^a = \exp(a \log g)$. *(proved here)* Lemma 7.67.

7.51 Grothendieck's monodromy theorem. For $\rho\colon G_K \to \mathrm{GL}(V)$ ℓ-adic, there is a unique nilpotent N with $\rho(\sigma) = \exp(t_\zeta(\sigma)N)$ on an open normal $I_1 \subseteq I_K$, and $\rho(w)N\rho(w)^{-1} = \|w\|N$; $N = 0$ iff $\rho(I_K)$ is finite. *(proved here)* Theorem 7.68.

7.52 Weil-Deligne representations (definition): pairs (r, N), with r a representation of W_K such that $r(I_K)$ is finite and N nilpotent, satisfying $r(w)Nr(w)^{-1} = \|w\|N$; Frobenius-semisimplicity. Definition 7.69.

7.53 Operations. Sums, tensor products, duals ($-N^{\mathsf{T}}$), Hom, ad^0 ($[N, \cdot\,]$), twists. *(proved here; Frobenius-semisimplification stated)* Proposition 7.70.

7.54 WD(ρ). $r(\Phi^n\sigma) = \rho(\Phi^n\sigma)\exp(-t_\zeta(\sigma)N)$ is a Weil-Deligne representation, independent of Φ and ζ up to isomorphism; equivalence of categories and independence of ℓ for elliptic curves are stated. *(proved here, except (iii), (iv): stated; reference)* Theorem 7.71.

7.55 $\mathrm{sp}(n)$ (definition): $r(w)e_i = \|w\|^i e_i$, $Ne_i = e_{i+1}$; twists $\mathrm{sp}(n) \otimes \mu$; unramified and ramified twists of Steinberg. Definition 7.72.

7.56 Two-dimensional Weil-Deligne representations. $\mathrm{sp}(n) \otimes \mu$ is indecomposable; an (r, N) of dimension 2 with $N \neq 0$ is Frobenius-semisimple and isomorphic to $\mathrm{sp}(2) \otimes \mu$ for a unique μ; the case $N = 0$ is stated. *(proved here, except (iii): stated; reference)* Proposition 7.73.

7.57 Inertia invariants. $V^{\rho(I_K)} = (\ker N)^{r(I_K)}$, with $\rho(\Phi) = r(\Phi)$ there. *(proved here)* Proposition 7.76.

7.58 Local L-factor (definition): $L(V, s) = \det(1 - \Phi q^{-s} \mid V^{I_K})^{-1}$, Φ geometric. Definition 7.77.

7.59 Properties of L-factors. Well defined, additive; $L(\mathbb{Q}_\ell(1), s) = (1-q^{-1-s})^{-1}$, $L(V(1), s) = L(V, s+1)$ (false with Frob); $L(\mathrm{sp}(2) \otimes \mu, s)$; $L_p(V_\ell E, s) = L_p(E, s+1)$ and $L_p(V_\ell E^\vee, s) = L_p(E, s)$. *(proved here)* Proposition 7.78.

7.60 Swan and Artin conductors (definition): $\mathrm{sw}(V) = \sum_{i\geq 1} \frac{g_i}{g_0} \dim V/V^{G_i}$, $a(V) = \dim V - \dim V^{I_K} + \mathrm{sw}(V)$. Definition 7.81.

7.61 Properties of the conductors. Independence of L and integrality (stated); $\mathrm{sw} = 0$ iff tame; additivity, invariance under unramified twists and base change; $a(\chi) = 1$ for tame χ, $a(\chi_{-4}) = 2$, $a(\chi_{\pm 8}) = 3$ at 2; the same for mod ℓ representations. *(proved here, except (i), (ii): stated; reference)* Theorem 7.82.

7.62 Conductor of a Weil-Deligne representation (definition): the exponent is $a(r, N) = \dim V - \dim(\ker N)^{r(I_K)} + \mathrm{sw}(r)$. Definition 7.83.

7.63 Properties. $a(\rho) = \dim V - \dim V^{I_K} + \mathrm{sw}(\rho)$; $a(V \otimes \chi) = \dim V \cdot a(\chi)$ for V unramified; $a(\mathrm{sp}(2) \otimes \mu) = 1$, $a(\mathrm{sp}(2) \otimes \mu\chi) = 2a(\chi)$; the conductor exponent of E at p is $a(V_\ell E)$ (definition, Chapter 10), equal to $v_p(\Delta_{\min}) + 1 - m$ with m the number of components of the special fibre of the minimal regular model (Ogg, Saito). *(proved here; independence of ℓ and Ogg's formula stated; reference)* Proposition 7.84.

7.64 Epsilon factors. Existence and uniqueness (Langlands, Deligne) and the Weil-Deligne correction factor. *(stated; reference)* Theorem 7.85.

7.65 Unramified shape. A has eigenvalues $\alpha/\beta, 1, \beta/\alpha$ for both Frobenii; $L(A,1)^{-1} = \frac{q-1}{q} \cdot \frac{(q+1)^2 - a^2}{q^2}$. *(proved here)* Proposition 7.86.

7.66 Finite cyclic tame inertia. Order 2: $V \otimes \chi$ unramified; orders $3, 4, 6$: $V^{I_q} = 0$, $a(V) = 2$, $A^{I_q} = \Omega(2g - \mathrm{tr}\, g)$ with Frob and Φ acting by $\chi(q)$, $\chi = \chi_{-3}$ or χ_{-4}, $L(A,s)^{-1} = 1 - \chi(q)q^{-s}$, $a(A) = 2$. *(proved here)* Proposition 7.87.

7.67 Steinberg and its twists. $a(\mathrm{sp}(2) \otimes \mu) = 1$, $a(\mathrm{sp}(2) \otimes \mu\chi) = 2a(\chi)$; $\mathrm{ad}^0 \mathrm{sp}(2) \simeq \mathrm{sp}(3) \otimes \|\cdot\|^{-1}$, $A^{I_q} = \Omega N$ with Φ-eigenvalue q^{-1}, $L(\mathrm{ad}^0 V, s) = (1 - q^{-1-s})^{-1}$ for both. *(proved here)* Proposition 7.88.

7.68 The table of shapes at a tame prime. $\rho(I_q)$, $\dim V^{I_q}$, $a(V)$, $L(V,s)$, $\dim A^{I_q}$, $L(A,s)$ for the six shapes, for $q \geq 5$ (and partly for $q = 2, 3$). *(proved here; the Kodaira column stated, Chapters 10 and 11)* Theorem 7.89.

7.69 The primes 2 and 3. An inertia image of order divisible by 3 is wild at 3 ($a \geq 3$); order 3 is tame at 2 with $L(A,s)^{-1} = 1 + 2^{-s}$; non-abelian finite images have $A^{I_q} = 0$; $a(\mathrm{sp}(2) \otimes \mu\chi) \in \{4, 6\}$ at 2. *(proved here)* Proposition 7.91.

Where the paper uses this chapter

- **Section 1.1** (the local terms): I_p and $D_p \simeq G_{\mathbb{Q}_p}$, Proposition 7.32; $\delta_p = \dim V^{I_p}$, Proposition 7.76; $L_p(A_f, s) = \det(1 - \mathrm{Frob}_p^{-1} p^{-s} \mid A_f^{I_p})^{-1}$ and the naive factor, Definition 7.77, Convention 7.37, Paper link 7.80.
- **Definition def:terms and the table of Section 1**: the shapes and their factors, Theorem 7.89; $e_\ell = 0$ at multiplicative primes, Proposition 7.88; potentially good I_n^* at 2, Remark 7.92.

- **Lemma lem:tamagawa-exp** (unramified at q modulo ℓ^t iff $\ell^t \mid n_q$): unramified base change, Proposition 7.38; $\mu_{\ell^\infty} \subset \mathbb{Q}_q^{\mathrm{ur}}$ and ℓ^t-th powers in $\mathbb{Q}_q^{\mathrm{ur}}$, Proposition 7.36(iv); Kummer theory on inertia, Theorem 7.58(v); Paper link 7.40, Paper link 7.59.

- **Lemma lem:IV and Remark rem:types**: $\mathbb{Z}_3[\zeta_3]$ as the ring of integers of $\mathbb{Q}_3(\sqrt{-3})$, Proposition 7.28; tame inertia images are cyclic and Frobenius acts by the q-th power, Corollary 7.52; wild inertia, Proposition 7.53; conductor exponents and the Serre conductor, Theorem 7.82(v), Proposition 7.84, Proposition 7.87; the value at $q = 2$, Proposition 7.91(ii).

7.1 Absolute values, completions, $\mathbb{Q}_p$ and $\mathbb{Z}_p$

This section builds the fields in which every local statement of the paper lives: $\mathbb{Q}_q$ at a bad prime q, and $\mathbb{Q}_\ell$, $\mathbb{Z}_\ell$ for the coefficients. Chapter 2 defined v_p and $|\cdot|_p$ on $\mathbb{Q}$, and Chapter 3 built $\mathbb{Z}_\ell$ algebraically as an inverse limit; here we complete $\mathbb{Q}$ analytically and show that the two constructions agree (Theorem 7.8(ii)). The paper uses these fields without comment in Sections 2 and 4; nothing in this section is a statement of the paper, but everything after it depends on it.

Convention 7.1 (local fields)**.** (a) p is a prime and K denotes $\mathbb{Q}_p$ or a finite extension of $\mathbb{Q}_p$ (Section 7.3), with valuation ring $\mathcal{O}_K$, maximal ideal $\mathfrak{m}_K$, uniformiser ϖ_K, residue field $k_K = \mathbb{F}_q$, $q = p^f$, normalised valuation v_K ($v_K(\varpi_K) = 1$) and normalised absolute value $|x|_K = q^{-v_K(x)}$. On $\mathbb{Q}_p$ we write v_p, $|\cdot|_p$ as in Chapter 2. The letter q is both $\#k_K$ and, when the paper's prime is meant, the bad prime q; the two agree for $K = \mathbb{Q}_q$, the field over which the paper works (when its unramified quadratic extension appears, its residue field is written $\mathbb{F}_{q^2}$). In the general theory the residue characteristic is p and $\ell \neq p$ is another prime; at the paper's prime, $\ell \neq q$.

(b) $\overline{\mathbb{Q}}_p$ is a fixed algebraic closure of $\mathbb{Q}_p$ and $G_K = \mathrm{Gal}(\overline{\mathbb{Q}}_p/K)$. Inside $\overline{\mathbb{Q}}_p$ we have $K \subseteq K^{\mathrm{ur}} \subseteq K^{\mathrm{tame}}$, the maximal unramified and the maximal tamely ramified extensions (Definition 7.35, Theorem 7.45); $I_K = \mathrm{Gal}(\overline{\mathbb{Q}}_p/K^{\mathrm{ur}})$ is the inertia group and $P_K = \mathrm{Gal}(\overline{\mathbb{Q}}_p/K^{\mathrm{tame}})$ the wild inertia group; for $K = \mathbb{Q}_p$ we write I_p, P_p.

(c) $\mathbb{Z}_\ell(1) = \varprojlim_k \mu_{\ell^k}$ (transition maps $\zeta \mapsto \zeta^\ell$), on which G_K acts through the cyclotomic character χ_ℓ; it is written additively when it receives the values of cocycles. Where a $\mathbb{Z}_\ell$-valued version is needed we fix a generator $\zeta = (\zeta_{\ell^k})_k$ of $\mathbb{Z}_\ell(1)$ and identify $\mathbb{Z}_\ell(1) \simeq \mathbb{Z}_\ell$ by $\zeta \mapsto 1$.

(d) Frob is an *arithmetic* Frobenius and $\Phi = \mathrm{Frob}^{-1}$ the *geometric* one (Convention 7.37); Φ without subscript is always the geometric Frobenius of the local field in question, and the geometric Frobenius at a named prime p is written Frob_p^{-1}. With a numerical subscript, as in Φ_{p^n} and Φ_3, the letter denotes a cyclotomic polynomial (Chapter 2); Φ_q^{geom} is the geometric component group of the Néron model at q (Chapter 10).

(e) Other letters: ε is an unramified character of order at most 2 (the paper's Tate data), ϵ an epsilon factor; θ_m are the tame characters of Theorem 7.47, θ_2 the character of order two of inertia, and η_{ur} the unramified quadratic character; $[a]$ is the Teichmüller lift of a; N is a monodromy operator (Sections 7.7 to 7.9), never a conductor; e is a ramification index, except in Section 7.9, where it is also the paper's basis vector $e = e_1 \otimes e_2^\vee$ of $\mathrm{ad}^0 T$, and we say which. Quadratic characters are χ_d, indexed by the fundamental discriminant d (χ_{-3}, χ_{-4}, χ_8, χ_{q^*}); a letter subscript χ_ℓ is the cyclotomic character.

7.1.1 Absolute values

Definition 7.2 (absolute values)**.** An *absolute value* on a field F is a map $|\cdot| : F \to \mathbb{R}_{\geq 0}$ with $|x| = 0$ iff $x = 0$, $|xy| = |x||y|$ and $|x+y| \leq |x|+|y|$. It is *nonarchimedean* if $|x+y| \leq \max(|x|, |y|)$ for all x, y (the ultrametric inequality), and *trivial* if $|x| = 1$ for all $x \neq 0$. Two absolute values are *equivalent* if they define the same topology. For a nonarchimedean $|\cdot|$ the *valuation ring* is $\mathcal{O} = \{|x| \leq 1\}$, its *maximal ideal* $\mathfrak{m} = \{|x| < 1\}$, and $k = \mathcal{O}/\mathfrak{m}$ the *residue field*. The absolute value is *discrete* if $|F^\times|$ is a discrete subgroup of $\mathbb{R}_{>0}$.

The definition abstracts the one example that matters here. On $\mathbb{Q}$, $|x|_p = p^{-v_p(x)}$ (Chapter 2) measures how divisible x is by p: $|12|_2 = \frac{1}{4}$, $|1/12|_2 = 4$, $|12|_3 = \frac{1}{3}$ and $|12|_5 = 1$. It is nonarchimedean, because a sum of two multiples of p^k is again a multiple of p^k, that is $v_p(x+y) \geq \min(v_p(x), v_p(y))$; and the inequality can be strict, as $|2+6|_2 = \frac{1}{8} < \frac{1}{2}$ shows. Its value group is $p^{\mathbb{Z}}$, so it is discrete; its valuation ring is $\mathbb{Z}_{(p)}$, the fractions a/b with $p \nmid b$, with maximal ideal $p\mathbb{Z}_{(p)}$ and residue field $\mathbb{F}_p$. Two numbers are p-adically close when their difference is divisible by a high power of p; completing $\mathbb{Q}$ for this notion of closeness is what produces $\mathbb{Q}_p$ below.

Proposition 7.3. *Let $|\cdot|$ be an absolute value on a field F.*

(i) $|\cdot|$ is nonarchimedean iff $|n\cdot 1|\le 1$ for all $n\in\mathbb{Z}$.

(ii) If $|\cdot|$ is nonarchimedean: $|x+y|=\max(|x|,|y|)$ whenever $|x|\neq|y|$; $\mathcal{O}$ is a subring of F, $\mathfrak{m}$ its unique maximal ideal and $\mathcal{O}^\times=\{|x|=1\}$; every point of an open ball $B(a,r)=\{|x-a|<r\}$ is a centre of it, and open balls are closed. If F is complete, a series $\sum a_n$ converges iff $a_n\to 0$.

(iii) If $|\cdot|$ is nonarchimedean, discrete and nontrivial, then $|F^\times|=c^{\mathbb{Z}}$ for a unique $c\in(0,1)$, there is a valuation $v\colon F^\times\to\mathbb{Z}$ with $|x|=c^{v(x)}$, and $\mathcal{O}$ is a discrete valuation ring with maximal ideal $\varpi\mathcal{O}$ for any ϖ with $v(\varpi)=1$.

(iv) Two nontrivial absolute values $|\cdot|_1$, $|\cdot|_2$ are equivalent iff $|\cdot|_1=|\cdot|_2^s$ for some $s>0$.

Proof. (i) If the ultrametric inequality holds, $|n\cdot 1|=|1+\cdots+1|\le 1$ by induction. Conversely, if $|n\cdot 1|\le 1$ for all n, then for every $k\ge 1$

$$|x+y|^k=\Big|\sum_{i=0}^{k}\tbinom{k}{i}x^iy^{k-i}\Big|\le (k+1)\max(|x|,|y|)^k,$$

since each binomial coefficient is an integer, hence of absolute value at most 1, and each $|x^iy^{k-i}|$ is at most $\max(|x|,|y|)^k$. Taking k-th roots gives $|x+y|\le (k+1)^{1/k}\max(|x|,|y|)$, and $(k+1)^{1/k}\to 1$ as $k\to\infty$, so $|x+y|\le\max(|x|,|y|)$.

(ii) If $|x|<|y|$ then $|y|=|(x+y)-x|\le\max(|x+y|,|x|)$ forces $|y|\le|x+y|$, and $|x+y|\le|y|$ always. The ultrametric inequality and multiplicativity show that $\mathcal{O}$ is a ring and $\mathfrak{m}$ an ideal; an element of $\mathcal{O}\setminus\mathfrak{m}$ has absolute value 1, so its inverse lies in $\mathcal{O}$; hence $\mathfrak{m}$ is the set of nonunits, the unique maximal ideal. If $|b-a|<r$ and $|x-a|<r$ then $|x-b|<r$, so $B(a,r)=B(b,r)$. If $c\notin B(a,r)$, then $B(c,r)\cap B(a,r)=\emptyset$ (a common point would make both balls equal), so the complement of $B(a,r)$ is open. Finally $|\sum_{i=n+1}^{m}a_i|\le\max_{n<i\le m}|a_i|$, so the partial sums are Cauchy iff $a_i\to 0$; in a complete field Cauchy sequences converge, and conversely if the partial sums s_n converge then $a_n=s_n-s_{n-1}\to 0$. (Over $\mathbb{R}$ the harmonic series shows that $a_n\to 0$ is not enough; the ultrametric inequality is what makes it so.)

(iii) A nontrivial discrete subgroup of $\mathbb{R}_{>0}$ (isomorphic by log to a discrete subgroup of $\mathbb{R}$) is infinite cyclic; let $c<1$ be its generator below 1 and $v(x)$ the integer with $|x|=c^{v(x)}$. Then v is a valuation: $v(xy)=v(x)+v(y)$ is multiplicativity, and $v(x+y)\ge\min(v(x),v(y))$ is the ultrametric inequality, c being less than 1. Moreover $\mathcal{O}=\{v\ge 0\}$, and every nonzero $x\in\mathcal{O}$ is $\varpi^{v(x)}u$ with $u=x\varpi^{-v(x)}$ of absolute value 1, a unit. If $I\neq 0$ is an ideal and n the least value of v on $I\setminus\{0\}$, then I contains some $\varpi^n u$, hence ϖ^n; and every $x\in I$ is $\varpi^n\cdot x\varpi^{-n}$ with $x\varpi^{-n}\in\mathcal{O}$. So $I=\varpi^n\mathcal{O}$, and $\mathcal{O}$ is a principal ideal domain with the single nonzero prime ideal $\varpi\mathcal{O}$, a discrete valuation ring (Chapter 3).

(iv) If $|\cdot|_1=|\cdot|_2^s$ the open balls coincide. Conversely, in the topology of $|\cdot|_i$ one has $|x|_i<1$ iff $x^n\to 0$; so equivalent absolute values have the same set $\{|x|<1\}$. Fix y with $|y|_1>1$ (it exists, the absolute value being nontrivial), so $|y|_2>1$ too, and put $s=\log|y|_1/\log|y|_2$. For $x\neq 0$ write $|x|_1=|y|_1^{\alpha}$. For integers m, $n>0$ with $m/n>\alpha$ we have $|x^n/y^m|_1<1$, hence $|x^n/y^m|_2<1$, that is $|x|_2<|y|_2^{m/n}$; likewise $m/n<\alpha$ gives $|x|_2>|y|_2^{m/n}$. So $|x|_2=|y|_2^{\alpha}$ and $|x|_1=|x|_2^s$. □

Lemma 7.4 (summation in a complete nonarchimedean field)**.** *Let F be complete for a nonarchimedean absolute value and $(a_i)_{i\in I}$ a countable family in F such that for every $\delta>0$ only finitely*

many $|a_i|$ exceed δ. Then $\sum_i a_i$ converges for every enumeration of I, to a sum independent of the enumeration; and for every partition $I = \bigsqcup_j I_j$ the partial sums $s_j = \sum_{i\in I_j} a_i$ satisfy the same hypothesis and $\sum_j s_j = \sum_i a_i$.

Proof. For an enumeration, the terms tend to 0, so the series converges by Proposition 7.3(ii). Given $\delta > 0$, let I_δ be the finite set of indices with $|a_i| > \delta$. Any partial sum of any enumeration that contains I_δ differs from $\sum_{i\in I_\delta} a_i$ by a finite sum of terms of absolute value at most δ, hence by at most δ; so two limits differ by at most δ, for every δ. For a partition, $|s_j| \le \max_{i\in I_j}|a_i|$, so only finitely many $|s_j|$ exceed δ, and $\sum_j s_j$ differs from $\sum_{i\in I_\delta} a_i$ by at most δ once the finitely many j meeting I_δ are included. □

Remark 7.5 (Ostrowski, product formula, weak approximation). By Ostrowski's theorem (Chapter 2) every nontrivial absolute value on $\mathbb{Q}$ is equivalent to $|\cdot|_\infty$ or to $|\cdot|_p$ for exactly one prime p, and $\prod_{v\le\infty}|x|_v = 1$ for $x \in \mathbb{Q}^\times$ (the product formula, also Chapter 2). For finitely many pairwise inequivalent absolute values $|\cdot|_1, \dots, |\cdot|_r$ on a field F and elements $a_1, \dots, a_r$, there is for every $\delta > 0$ an $x \in F$ with $|x - a_i|_i < \delta$ for all i (weak approximation). We do not prove this; see Neukirch [142, Chapter II, Section 3]. It is not used in the book.

7.1.2 Completions

Theorem 7.6 (completion). *Let F be a field with an absolute value $|\cdot|$. There is a field $\hat F$ containing F, with an absolute value extending $|\cdot|$, which is complete and in which F is dense; it is unique up to a unique isometric F-isomorphism. If $|\cdot|$ is nonarchimedean, then:*

(i) $|\hat F^\times| = |F^\times|$, and the extended absolute value is nonarchimedean;

(ii) the valuation ring $\hat{\mathcal{O}}$ of $\hat F$ is the closure of $\mathcal{O}$, and if $|\cdot|$ is discrete with uniformiser ϖ, then $\mathcal{O}/\varpi^n\mathcal{O} \to \hat{\mathcal{O}}/\varpi^n\hat{\mathcal{O}}$ is an isomorphism for every $n \ge 1$ (so the residue field does not change);

(iii) if $|\cdot|$ is discrete, $\hat{\mathcal{O}} \to \varprojlim_n \mathcal{O}/\varpi^n\mathcal{O}$, $x \mapsto (x \bmod \varpi^n)_n$, is an isomorphism of topological rings, the right side carrying the inverse limit of the discrete topologies.

Proof. Let C be the ring of Cauchy sequences in F (termwise operations) and $\mathfrak{n} \subset C$ the ideal of sequences tending to 0. If $(x_n) \in C \setminus \mathfrak{n}$, then $|x_n|$ is bounded below by some $\delta > 0$ for $n \ge n_0$ (otherwise a subsequence tends to 0 and so does the Cauchy sequence); then $(x_n^{-1})_{n\ge n_0}$ is Cauchy, since $|x_n^{-1} - x_m^{-1}| \le \delta^{-2}|x_m - x_n|$. So $\mathfrak{n}$ is a maximal ideal and $\hat F = C/\mathfrak{n}$ is a field; F embeds by constant sequences. Put $|(x_n)| = \lim|x_n|$, which exists since $||x_n| - |x_m|| \le |x_n - x_m|$, and depends only on the class modulo $\mathfrak{n}$. It is an absolute value extending $|\cdot|$: multiplicativity and the triangle inequality hold term by term, $|x_ny_n| = |x_n||y_n|$ and $|x_n + y_n| \le |x_n| + |y_n|$, and survive the limit; $\lim|x_n| = 0$ means $(x_n) \in \mathfrak{n}$, the zero class; and a constant sequence has the absolute value of its term. The class of (x_n) is the limit of the constants x_n, so F is dense; and a Cauchy sequence of classes converges to the class of a diagonal sequence of approximating elements of F, so $\hat F$ is complete. If F' is another such field, the identity of F extends uniquely to an isometry $\hat F \to F'$ by continuity (send $\lim x_n$ to $\lim x_n$), which is a field isomorphism.

(i) Let $\hat x = \lim x_n \ne 0$ with $x_n \in F$. For n large, $|x_n - \hat x| < |\hat x|$, so $|x_n| = |\hat x|$ by Proposition 7.3(ii) applied in $\hat F$, where the ultrametric inequality holds by passing to the limit. Hence the value groups agree.

(ii) If $|\hat{x}| \le 1$ and $x_n \to \hat{x}$ with $x_n \in F$, then $|x_n| \le 1$ for n large; so $\hat{\mathcal{O}}$ is the closure of $\mathcal{O}$, and $\hat{\mathcal{O}} \cap F = \mathcal{O}$. By (i), ϖ is a uniformiser of $\hat{F}$. The map $\mathcal{O} \to \hat{\mathcal{O}}/\varpi^n\hat{\mathcal{O}}$ is surjective, because every $\hat{x} \in \hat{\mathcal{O}}$ has an $x \in F$ with $|x - \hat{x}| \le |\varpi|^n$, and then $x \in \mathcal{O}$; its kernel is $\mathcal{O} \cap \varpi^n\hat{\mathcal{O}} = \varpi^n\mathcal{O}$.

(iii) By (ii), $\hat{\mathcal{O}}/\varpi^n\hat{\mathcal{O}} = \mathcal{O}/\varpi^n\mathcal{O}$. The map is injective because $\bigcap_n \varpi^n\hat{\mathcal{O}} = 0$. It is surjective: given a compatible family $(x_n \bmod \varpi^n)$ with $x_n \in \mathcal{O}$, the sequence (x_n) is Cauchy, since $x_m - x_n \in \varpi^n\mathcal{O}$ for $m \ge n$, and its limit maps to the family. The ideals $\varpi^n\hat{\mathcal{O}}$ are a basis of neighbourhoods of 0 on the left and correspond to the kernels of the projections on the right, so the bijection is a homeomorphism. □

7.1.3 The field $\mathbb{Q}_p$

Definition 7.7. $\mathbb{Q}_p$ is the completion of $\mathbb{Q}$ for $|\cdot|_p$, and $\mathbb{Z}_p = \{x \in \mathbb{Q}_p : |x|_p \le 1\}$ is the ring of *p-adic integers*. The valuation v_p extends to $\mathbb{Q}_p^\times$ by $|x|_p = p^{-v_p(x)}$ (Theorem 7.6(i)).

Theorem 7.8. *(i) $\mathbb{Z}_p$ is the closure of $\mathbb{Z}$, and of $\mathbb{Z}_{(p)}$, in $\mathbb{Q}_p$. It is a complete discrete valuation ring with uniformiser p, residue field $\mathbb{F}_p$ and nonzero ideals $p^n\mathbb{Z}_p$.*

(ii) The map $\mathbb{Z}_p \to \varprojlim_n \mathbb{Z}/p^n\mathbb{Z}$, $x \mapsto (x \bmod p^n)_n$, is an isomorphism of topological rings. So the $\mathbb{Z}_p$ of this chapter is the ring $\mathbb{Z}_\ell$ built algebraically in Chapter 3 (at $\ell = p$), and the profinite group of Chapter 1.

(iii) $\mathbb{Z}_p^\times = \{|x|_p = 1\}$, and $x \in \mathbb{Z}_p$ is a unit iff $x \not\equiv 0 \pmod p$. Every $x \in \mathbb{Q}_p^\times$ is uniquely $x = p^{v_p(x)}u$ with $u \in \mathbb{Z}_p^\times$; so $\mathbb{Q}_p^\times = p^{\mathbb{Z}} \times \mathbb{Z}_p^\times$ and $\mathbb{Q}_p = \mathbb{Z}_p[1/p] = \operatorname{Frac}\mathbb{Z}_p$.

(iv) $\mathbb{Z}_p$ is compact; $\mathbb{Q}_p$ is locally compact and totally disconnected.

(v) For a prime $q \ne p$, $q \in \mathbb{Z}_p^\times$, so $q^{-1} \in \mathbb{Z}_p$, and q^a is defined for every $a \in \mathbb{Z}_p$ when $q \in 1+p\mathbb{Z}_p$ (Theorem 7.18).

Proof. (i) The absolute value $|\cdot|_p$ on $\mathbb{Q}$ is discrete with value group $p^{\mathbb{Z}}$ and valuation ring $\mathbb{Z}_{(p)}$, whose residue field is $\mathbb{F}_p$ (Chapter 2). By Theorem 7.6, $\mathbb{Z}_p$ is the closure of $\mathbb{Z}_{(p)}$ and a complete discrete valuation ring with uniformiser p and residue field $\mathbb{Z}_{(p)}/p\mathbb{Z}_{(p)} = \mathbb{F}_p$, and its nonzero ideals are $p^n\mathbb{Z}_p$ (Proposition 7.3(iii)). $\mathbb{Z}$ is dense in $\mathbb{Z}_{(p)}$: for $a/b \in \mathbb{Z}_{(p)}$ and $n \ge 1$, b is invertible modulo p^n, and an integer c with $bc \equiv a \pmod{p^n}$ has $|a/b - c|_p \le p^{-n}$. (ii) is Theorem 7.6(iii) with $\mathcal{O} = \mathbb{Z}_{(p)}$, $\varpi = p$, since $\mathbb{Z}_{(p)}/p^n\mathbb{Z}_{(p)} = \mathbb{Z}/p^n\mathbb{Z}$. (iii) Units of the valuation ring are the elements of absolute value 1 (Proposition 7.3(ii)), that is, those not in $p\mathbb{Z}_p$. For $x \ne 0$, $u = xp^{-v_p(x)}$ has absolute value 1. (iv) By (ii), $\mathbb{Z}_p$ is homeomorphic to a closed subset of the product $\prod_n \mathbb{Z}/p^n$ of finite discrete sets, which is compact (Tychonoff; Chapter 1). $\mathbb{Z}_p$ is an open neighbourhood of 0, and $x + \mathbb{Z}_p$ of x, so $\mathbb{Q}_p$ is locally compact. Balls are open and closed (Proposition 7.3(ii)) and arbitrarily small, so the connected components are points: if a subset S contains $x \ne y$, the ball $B = B(x, |x-y|_p)$ contains x but not y, and $S = (S \cap B) \sqcup (S \setminus B)$ writes S as a disjoint union of two nonempty relatively open sets. (v) q is an integer not divisible by p. □

Warning 7.9. Chapter 3 defines $\mathbb{Z}_\ell = \varprojlim \mathbb{Z}/\ell^n$ and proves that it is a complete discrete valuation ring; Theorem 7.8(ii) shows that this is the closure of $\mathbb{Z}$ in the completion $\mathbb{Q}_\ell$ of $\mathbb{Q}$. Every statement about $\mathbb{Z}_\ell$ in either chapter therefore applies to the other construction. The two topologies agree as well, so "continuous" means the same thing in both.

Proposition 7.10 (p-adic expansions)**.** *Every $x \in \mathbb{Q}_p^\times$ has a unique expansion*

$$x = \sum_{i \geq v} a_i p^i, \qquad v = v_p(x), \quad a_i \in \{0, 1, \dots, p-1\}, \quad a_v \neq 0,$$

converging in $\mathbb{Q}_p$. $x \in \mathbb{Z}_p$ iff $v \geq 0$, and for $x \in \mathbb{Z}_p$ the partial sum $\sum_{i<n} a_i p^i$ is the integer in $[0, p^n)$ congruent to x modulo p^n. The number x lies in $\mathbb{Q}$ iff its digit sequence (a_i) is eventually periodic.

Proof. Multiplying by a power of p we may assume $x \in \mathbb{Z}_p^\times$. Let $s_n \in [0, p^n)$ be the integer congruent to x modulo p^n (Theorem 7.8(ii)). Then $s_{n+1} \equiv s_n \pmod{p^n}$, so $s_{n+1} = s_n + a_n p^n$ with $a_n \in \{0, \dots, p-1\}$, and $s_n \to x$; this gives the expansion, and uniqueness holds because the partial sums of any expansion are the s_n. A sum $\sum a_i p^i$ with integer digits converges by Proposition 7.3(ii). If the digits are periodic of period k from the index m on, then $x = A + p^m B/(1 - p^k)$ with integers A, B, a rational number. Conversely let $x = a/b \in \mathbb{Z}_p \cap \mathbb{Q}$ with $b \geq 1$, $p \nmid b$, and put $x_n = (x - s_n)/p^n$, the number whose digits are $a_n, a_{n+1}, \dots$. Since $b s_n \equiv a \pmod{p^n}$, $b x_n = (a - b s_n)/p^n$ is an integer, and as $0 \leq s_n < p^n$ it lies in the interval $(a/p^n - b,\ a/p^n]$, which for all n is contained in $(-|a| - b, |a|]$. So the x_n take finitely many values, $x_n = x_m$ for some $n < m$, and the digit sequence is periodic from n on, with period $m - n$. □

Example 7.11. $-1 = \sum_{i \geq 0} (p-1) p^i$, since $s_n = p^n - 1$; and $1/(1-p) = \sum_{i \geq 0} p^i$. For readers who know Laurent series from Riley, Hobson and Bence: a p-adic number is a "Laurent series in p" with digits in $\{0, \dots, p-1\}$, but arithmetic carries from one digit to the next, so the digits of a sum are not the sums of the digits. In $\mathbb{Z}_5$, the digits of $\sqrt{-1}$ (a root of $X^2 + 1$ congruent to 2 modulo 5, Example 7.16) begin $2, 1, 2, 1$: that root is $\equiv 182 \pmod{5^4}$.

7.2 Hensel's lemma; units, roots of unity and powers

This section answers the questions the paper asks about elements of $\mathbb{Q}_q$ and $\mathbb{Z}_\ell$: when a polynomial has a root (Hensel's lemma), which roots of unity lie in $\mathbb{Q}_p$, what $\mathbb{Z}_p^\times$ and $\mathbb{Q}_p^\times$ look like, and when an element is an ℓ^k-th power. The paper uses the last answer in Lemma lem:tamfactor, where "the reduction of u is an ℓ^k-th power in $\mathbb{F}_q^\times$" is equivalent to u being an ℓ^k-th power in $\mathbb{Z}_q^\times$ (Theorem 7.20(ii)), and in Lemma lem:tamagawa-exp, through the units of $\mathbb{Q}_q^{\mathrm{ur}}$ (Proposition 7.36(iv)). The rings $\mathbb{Z}_\ell[\zeta_3]$ and $\mathbb{Z}_\ell[i]$ of Lemma lem:euler are decided here too (Example 7.16(g)).

7.2.1 Hensel's lemma

Theorem 7.12 (Hensel's lemma)**.** *Let K be a field complete for a nonarchimedean absolute value, with valuation ring $\mathcal{O}$ and maximal ideal $\mathfrak{m}$, and let $f \in \mathcal{O}[X]$.*

(a) (Newton form.) If $a_0 \in \mathcal{O}$ satisfies $|f(a_0)| < |f'(a_0)|^2$, then the Newton sequence $a_{n+1} = a_n - f(a_n)/f'(a_n)$ is defined, lies in $\mathcal{O}$ and converges to a root a of f. It is the unique root of f with $|a - a_0| < |f'(a_0)|$; moreover $|a - a_0| = |f(a_0)/f'(a_0)|$ and $|f'(a)| = |f'(a_0)|$.

(b) (Simple-root form.) If $a_0 \in \mathcal{O}$ satisfies $f(a_0) \equiv 0 \pmod{\mathfrak{m}}$ and $f'(a_0) \not\equiv 0 \pmod{\mathfrak{m}}$, there is a unique $a \in \mathcal{O}$ with $f(a) = 0$ and $a \equiv a_0 \pmod{\mathfrak{m}}$.

Proof. (a) Taylor's formula in $\mathcal{O}[x,h]$ reads $f(x+h)=f(x)+f'(x)h+h^2g(x,h)$ and $f'(x+h)=f'(x)+hg_1(x,h)$ with $g,g_1\in\mathcal{O}[x,h]$: for $f=\sum c_kX^k$, expand each $(x+h)^k=x^k+kx^{k-1}h+\sum_{j\geq 2}\binom{k}{j}x^{k-j}h^j$ by the binomial theorem; the integer binomial coefficients keep all coefficients in $\mathcal{O}$, and no division by $j!$ occurs. The idea of the proof is the one of Newton's method over $\mathbb{R}$: the error is squared at each step. Put $c=|f'(a_0)|$ and $\delta=|f(a_0)|/c^2<1$. We show by induction that $a_n\in\mathcal{O}$, $|f'(a_n)|=c$ and $|f(a_n)|\leq c^2\delta^{2^n}$. This holds for $n=0$. Given it for n, the step $h_n=-f(a_n)/f'(a_n)$ has $|h_n|=|f(a_n)|/c\leq c\,\delta^{2^n}<c\leq 1$, so $a_{n+1}=a_n+h_n\in\mathcal{O}$; $|f'(a_{n+1})-f'(a_n)|=|h_ng_1(a_n,h_n)|\leq|h_n|<c$ gives $|f'(a_{n+1})|=c$ (Proposition 7.3(ii)); and since h_n was chosen so that $f(a_n)+f'(a_n)h_n=0$, Taylor's formula leaves $f(a_{n+1})=h_n^2g(a_n,h_n)$, which gives $|f(a_{n+1})|\leq|h_n|^2\leq c^2\delta^{2^{n+1}}$. Hence $|a_{n+1}-a_n|=|h_n|\to 0$, the sequence converges to some $a\in\mathcal{O}$, and $f(a)=\lim f(a_n)=0$, $|f'(a)|=c$. If $f(a_0)=0$, every h_n is 0, $a=a_0$ and $|a-a_0|=0=|f(a_0)/f'(a_0)|$; so assume $\delta>0$. For $n\geq 1$, $|h_n|\leq c\delta^{2^n}<c\delta=|h_0|$, so $|a-a_0|=|h_0|=|f(a_0)/f'(a_0)|<c$. If b is a root with $|b-a_0|<c$, then $h=b-a$ has $|h|<c$, and $0=f(b)=f'(a)h+h^2g(a,h)$; if $h\neq 0$ this gives $c=|f'(a)|=|hg(a,h)|\leq|h|<c$, which is absurd. (b) is (a) with $|f'(a_0)|=1$, since $|f(a_0)|<1$ and $|a-a_0|<1$ means $a\equiv a_0 \pmod{\mathfrak{m}}$. □

Warning 7.13. The simple-root form needs $f'(a_0)$ to be a unit. X^2-p has the root 0 modulo p but no root in $\mathbb{Q}_p$, since $v_p(x^2)$ is even. On the other hand X^2+7 has no simple root modulo 2 (its derivative $2X$ vanishes there), yet -7 is a square in $\mathbb{Z}_2$: with $a_0=1$, $|f(1)|_2=|8|_2=\frac{1}{8}<\frac{1}{4}=|f'(1)|_2^2$, so the Newton form applies, and the root is $\equiv 1 \pmod 4$. The iteration can be followed by hand: $a_1=1-8/2=-3$ with $f(-3)=16$, then $a_2=-3-16/(-6)=-\frac{1}{3}$ with $f(-\frac{1}{3})=\frac{64}{9}$. So $|f(a_n)|_2=\frac{1}{8},\frac{1}{16},\frac{1}{64}$, exactly the bound $c^2\delta^{2^n}$ of the proof with $c=\frac{1}{2}$, $\delta=\frac{1}{2}$. The root is $\equiv 181 \pmod{2^8}$, and indeed $-\frac{1}{3}\equiv 85 \pmod{2^8}$ agrees with it modulo 2^5, as $|a-a_2|_2=|f(a_2)/f'(a_2)|_2=2^{-5}$ predicts.

Theorem 7.14 (Hensel's lemma, factorisation form)**.** *Let $\mathcal{O}$ be a complete discrete valuation ring with uniformiser ϖ and residue field k, and let $f\in\mathcal{O}[X]$. Suppose that its reduction is $\bar f=\bar g\bar h$ in $k[X]$ with $\bar g$ monic and $\bar g$, $\bar h$ coprime. Then $f=gh$ with $g,h\in\mathcal{O}[X]$, g monic of degree* $\deg\bar g$*, and g, h reducing to $\bar g$, $\bar h$.*

Proof. Choose $a,b\in\mathcal{O}[X]$ with $\bar a\bar g+\bar b\bar h=1$, a monic lift g_1 of $\bar g$ of degree $m=\deg\bar g$, and a lift h_1 of $\bar h$. We construct g_k monic of degree m and h_k with $f\equiv g_kh_k \pmod{\varpi^k}$, $g_{k+1}\equiv g_k$ and $h_{k+1}\equiv h_k \pmod{\varpi^k}$. Given g_k, h_k, write $f-g_kh_k=\varpi^kr$. In $k[X]$, divide $\bar r\bar b$ by the monic $\bar g$: $\bar r\bar b=\bar s\bar g+\bar u$ with $\deg\bar u<m$; then $\bar r=\bar r(\bar a\bar g+\bar b\bar h)=\bar g(\bar r\bar a+\bar s\bar h)+\bar h\bar u$. Lift $\bar u$ to u of degree $<m$ and $\bar r\bar a+\bar s\bar h$ to w, and put $g_{k+1}=g_k+\varpi^ku$, $h_{k+1}=h_k+\varpi^kw$. Then g_{k+1} is monic of degree m and $f-g_{k+1}h_{k+1}\equiv\varpi^k(r-g_kw-h_ku)\equiv 0 \pmod{\varpi^{k+1}}$, since $\bar g_k=\bar g$, $\bar h_k=\bar h$ and $\bar r=\bar g\bar w+\bar h\bar u$ (the term $\varpi^{2k}uw$ is divisible by ϖ^{k+1}). As $g_{k+1}\equiv g_k \pmod{\varpi^k}$, the coefficients of the g_k are Cauchy sequences, so they converge, and $g=\lim g_k$ is monic of degree m. Divide f by g in $\mathcal{O}[X]$: $f=gh+\rho$ with $\deg\rho<m$. Since $g\equiv g_k \pmod{\varpi^k}$, we have $gh_k\equiv f \pmod{\varpi^k}$, so $f-gh_k=\varpi^kt$ for some $t\in\mathcal{O}[X]$; dividing t by the monic g shows that the remainder of f on division by g, which is ρ, is $\equiv 0 \pmod{\varpi^k}$ (uniqueness of division by a monic polynomial). This holds for every k, so $\rho=0$ and $f=gh$. Finally $\bar g\bar h=\bar f=\bar g\,\bar h'$ for the reduction $\bar h'$ of h, and $k[X]$ is a domain, so h reduces to $\bar h$. □

Corollary 7.15. *Let K be complete for a discrete valuation, with valuation ring $\mathcal{O}$, and let $f=a_nX^n+\cdots+a_0\in K[X]$ be irreducible with $a_0a_n\neq 0$. Then* $\max_i|a_i|=\max(|a_0|,|a_n|)$*. In particular a monic irreducible polynomial over K with constant term in $\mathcal{O}$ lies in $\mathcal{O}[X]$.*

Proof. Scale f so that $\max_i|a_i| = 1$, and suppose $|a_0| < 1$ and $|a_n| < 1$. Let r be the least index with $|a_r| = 1$; then $0 < r < n$ and $\bar{f} = X^r\bar{h}$ with $\bar{h}(0) = \bar{a}_r \neq 0$, so X^r and $\bar{h}$ are coprime. Theorem 7.14 gives $f = gh$ with g monic of degree r; then $\deg h = n - r \geq 1$, contradicting irreducibility. For the last statement, $|a_n| = 1 \geq |a_0|$, so $\max_i|a_i| = \max(|a_0|, 1) = 1$, that is, every coefficient lies in $\mathcal{O}$. □

Read in reverse, the corollary is a reducibility test. For $f = X^2 + p^{-1}X + 1$ over $\mathbb{Q}_p$ the middle coefficient has $|p^{-1}|_p = p$, larger than $|a_0| = |a_2| = 1$; so f is reducible and has two roots in $\mathbb{Q}_p$. Directly: $pf = pX^2 + X + p$ reduces to X modulo p, and Theorem 7.14 splits off a linear factor. The roots have valuations 1 and -1 (their product is 1 and their sum $-p^{-1}$); for $p = 3$, PARI's `polrootspadic` gives $2 \cdot 3 + 2 \cdot 3^2 + \dots$ and $2 \cdot 3^{-1} + 2 + \dots$.

Example 7.16 (Hensel's lemma at work)**.** All residues below were computed by Newton's iteration and checked with PARI/GP (`polrootspadic`).

(a) $X^2 + 1$ over $\mathbb{Z}_5$ has the simple roots $2, 3$ modulo 5; the two roots in $\mathbb{Z}_5$ are $\equiv 182$ and $\equiv 443 \pmod{5^4}$, and $182^2 + 1 = 53 \cdot 5^4$.

(b) $\sqrt{-3} \in \mathbb{Z}_7$: the roots of $X^2 + 3$ are $\equiv 37, 306 \pmod{7^3}$. $\sqrt{2} \in \mathbb{Z}_7$: the roots of $X^2 - 2$ are $\equiv 108, 235 \pmod{7^3}$.

(c) $X^2 + X + 1$ has the simple roots $2, 4$ modulo 7, and its roots in $\mathbb{Z}_7$ are $\equiv 30, 18 \pmod{49}$. For instance, one Newton step from $a_0 = 2$, where $f(2) = 7$ and $f'(2) = 5$, gives $a_1 = 2 - 7 \cdot 5^{-1} \equiv 2 - 7 \cdot 10 = -68 \equiv 30 \pmod{49}$, since $5 \cdot 10 \equiv 1 \pmod{49}$; and $30^2 + 30 + 1 = 931 = 19 \cdot 49$. Hence $\mathbb{Z}_7[\zeta_3] := \mathbb{Z}_7[X]/(X^2 + X + 1) \simeq \mathbb{Z}_7 \times \mathbb{Z}_7$ by the Chinese remainder theorem, the two roots differing by a unit.

(d) (Squares in $\mathbb{Z}_2$.) $u \in \mathbb{Z}_2^\times$ is a square iff $u \equiv 1 \pmod 8$. If $u \equiv 1 \pmod 8$, apply Theorem 7.12(a) to $X^2 - u$ with $a_0 = 1$: $|1 - u|_2 \leq \frac{1}{8} < \frac{1}{4} = |2|_2^2$. Conversely an odd square is $\equiv 1 \pmod 8$. So -7, 17 are squares in $\mathbb{Z}_2$, and -1, 3, 5 are not.

(e) (Squares in $\mathbb{Z}_p$, p odd.) $u \in \mathbb{Z}_p^\times$ is a square iff $\bar{u}$ is a square in $\mathbb{F}_p$: the roots of $X^2 - \bar{u}$ are simple as $2\bar{u} \neq 0$.

(f) (Roots of $X^m - u$.) More generally, for $p \nmid m$ and $u \in \mathbb{Z}_p^\times$, every root of $X^m - \bar{u}$ in $\mathbb{F}_p$ is simple and lifts uniquely.

(g) (The rings $\mathbb{Z}_\ell[\zeta_3]$ and $\mathbb{Z}_\ell[i]$.) Let $g = X^2 + X + 1$ (resp. $X^2 + 1$) and $R = \mathbb{Z}_\ell[X]/(g)$. If $\ell \equiv 1 \pmod 3$ (resp. $\pmod 4$), $\bar{g}$ has two simple roots in $\mathbb{F}_\ell$, they lift by (b) of the theorem, and $R \simeq \mathbb{Z}_\ell \times \mathbb{Z}_\ell$, which is not a domain. If $\ell \equiv 2 \pmod 3$ (resp. $\ell \equiv 3 \pmod 4$), $\bar{g}$ is irreducible over $\mathbb{F}_\ell$, so g is irreducible over $\mathbb{Q}_\ell$ (a factorisation over $\mathbb{Q}_\ell$ would be into monic factors in $\mathbb{Z}_\ell[X]$ by Corollary 7.15, and would reduce to one of $\bar{g}$); then R is a domain, $R/\ell R = \mathbb{F}_\ell[X]/(\bar{g}) \simeq \mathbb{F}_{\ell^2}$ is a field, and an element of R outside ℓR is a unit (it is invertible modulo ℓ, and R is ℓ-adically complete), so R is a discrete valuation ring with uniformiser ℓ and residue field $\mathbb{F}_{\ell^2}$, the ring of integers of the unramified quadratic extension of $\mathbb{Q}_\ell$ (Theorem 7.34). For $\ell = 3$ (resp. $\ell = 2$), R is the ring of integers of a ramified quadratic extension: of $\mathbb{Q}_3(\sqrt{-3})$ by Proposition 7.28(ii), and of $\mathbb{Q}_2(i)$ because $1 + i$ is a root of the Eisenstein polynomial $X^2 - 2X + 2$, so that $\mathbb{Z}_2[i] = \mathbb{Z}_2[1 + i]$ is that ring of integers by Theorem 7.27 (Example 7.43(a)). This is the trichotomy that Chapter 6 stated for $\mathbb{Z}_\ell \otimes \mathbb{Z}[\zeta_3]$ and $\mathbb{Z}_\ell \otimes \mathbb{Z}[i]$, now with the local input proved; it is why the paper's $\mathrm{End}_{I_q}(T) = \mathbb{Z}_\ell \otimes \mathbb{Z}[\zeta_3]$ is not a field for $\ell \equiv 1 \pmod 3$.

7.2.2 Teichmüller lifts and the structure of the units

Theorem 7.17 (Teichmüller lifts)**.** *Let K be complete for a discrete valuation with finite residue field $k = \mathbb{F}_q$, $q = p^f$.*

(i) For $a \in k$ and any lift $\tilde{a} \in \mathcal{O}$, the limit $[a] = \lim_{n\to\infty} \tilde{a}^{q^n}$ exists and does not depend on $\tilde{a}$; $[a]$ is the unique lift of a with $[a]^q = [a]$.

(ii) $a \mapsto [a]$ is multiplicative, $[0] = 0$, and it restricts to an isomorphism $k^\times \to \mu_{q-1}(K)$ inverse to reduction. It is not additive.

(iii) $\mathcal{O}^\times = \mu_{q-1}(K) \times U^{(1)}$ with $U^{(1)} = 1 + \mathfrak{m}$, the projection to the first factor being $u \mapsto [\bar{u}]$.

Proof. First, if $x \equiv y \pmod{\mathfrak{m}^j}$ with $j \geq 1$, then $x^p \equiv y^p \pmod{\mathfrak{m}^{j+1}}$: indeed $x^p - y^p = (x-y)\sum_{i=0}^{p-1} x^i y^{p-1-i}$ and the sum is $\equiv p y^{p-1} \equiv 0 \pmod{\mathfrak{m}}$. Iterating, $x^q \equiv y^q \pmod{\mathfrak{m}^{j+1}}$. (i) Since $a^q = a$ in k, $\tilde{a}^q \equiv \tilde{a} \pmod{\mathfrak{m}}$, hence $\tilde{a}^{q^{n+1}} \equiv \tilde{a}^{q^n} \pmod{\mathfrak{m}^{n+1}}$; the sequence is Cauchy, its limit $[a]$ satisfies $[a]^q = [a]$ and reduces to a. Two lifts are congruent modulo $\mathfrak{m}$, so their q^n-th powers are congruent modulo $\mathfrak{m}^{n+1}$, and the limits agree. The polynomial $X^q - X$ has derivative $qX^{q-1} - 1 \equiv -1$, a unit, so by Theorem 7.12(b) it has a unique root lifting a. (ii) $[a][b]$ is a root of $X^q - X$ lifting ab, hence equals $[ab]$. For $a \neq 0$, $[a]^{q-1} = 1$; conversely every $\zeta \in \mu_{q-1}(K)$ is a root of $X^q - X$, so $\zeta = [\bar{\zeta}]$. In $\mathbb{Z}_5$, $[1] + [1] = 2 \neq [2] \equiv 182 \pmod{5^4}$. (iii) For $u \in \mathcal{O}^\times$, $u = [\bar{u}] \cdot u[\bar{u}]^{-1}$ with the second factor in $U^{(1)}$, and $\mu_{q-1}(K) \cap U^{(1)} = \{1\}$ by (ii). □

For example, in $\mathbb{Z}_5$ one has $[1], [2], [3], [4] \equiv 1, 182, 443, 624 \pmod{5^4}$; so $[2]$ and $[3]$ are the two square roots of -1 of Example 7.16(a), and $[4] = -1$.

Theorem 7.18 (structure of the units)**.** *(i) Let p be odd. The series*

$$\exp(x) = \sum_{n\geq 0} \frac{x^n}{n!}, \qquad \log(1+x) = \sum_{n\geq 1} (-1)^{n+1} \frac{x^n}{n}$$

converge for $x \in p\mathbb{Z}_p$ and give mutually inverse isomorphisms of topological groups $p\mathbb{Z}_p \simeq 1 + p\mathbb{Z}_p$, carrying $p^n\mathbb{Z}_p$ onto $1 + p^n\mathbb{Z}_p$ for every $n \geq 1$. Hence $1 + p\mathbb{Z}_p \simeq \mathbb{Z}_p$, topologically generated by $1 + p$, $\mathbb{Z}_p^\times = \mu_{p-1} \times (1 + p\mathbb{Z}_p)$, and

$$\mathbb{Q}_p^\times = p^{\mathbb{Z}} \times \mu_{p-1} \times (1 + p\mathbb{Z}_p) \simeq \mathbb{Z} \times \mathbb{Z}/(p-1) \times \mathbb{Z}_p.$$

(ii) For $p = 2$ the same series give $4\mathbb{Z}_2 \simeq 1 + 4\mathbb{Z}_2$, carrying $2^n\mathbb{Z}_2$ onto $1 + 2^n\mathbb{Z}_2$ for $n \geq 2$; $1 + 4\mathbb{Z}_2 \simeq \mathbb{Z}_2$ is topologically generated by 5, $\mathbb{Z}_2^\times = \{\pm 1\} \times (1 + 4\mathbb{Z}_2)$ and $\mathbb{Q}_2^\times \simeq \mathbb{Z} \times \mathbb{Z}/2 \times \mathbb{Z}_2$.

(iii) These are the inverse limits of the finite statements of Chapter 2: $(\mathbb{Z}/p^k)^\times$ is cyclic for p odd, and $(\mathbb{Z}/2^k)^\times = \{\pm 1\} \times \langle 5 \rangle$ for $k \geq 2$.

(iv) Let K be complete for a discrete valuation with residue field $\mathbb{F}_q$. Then $K^\times = \varpi^{\mathbb{Z}} \times \mu_{q-1}(K) \times U^{(1)}$; the quotients $U^{(i)}/U^{(i+1)}$, $U^{(i)} = 1 + \mathfrak{m}^i$, are isomorphic to the additive group of $\mathbb{F}_q$; $U^{(1)}$ is an abelian pro-p group, hence a $\mathbb{Z}_p$-module; and $U^{(1)}$ is uniquely m-divisible for every m prime to p.

Proof. We use $v = v_p$ and two estimates for $n \geq 1$: $v(n!) \leq (n-1)/(p-1)$ (Legendre's formula $v(n!) = (n - s_p(n))/(p-1)$, $s_p(n) \geq 1$ the digit sum, Chapter 2) and $v(n) \leq (n-1)/(p-1)$ (if

$v(n) = k$ then $n \geq p^k$ and $p^k - 1 = (p-1)(1 + p + \cdots + p^{k-1}) \geq (p-1)k$). Let $c = 1$ if p is odd and $c = 2$ if $p = 2$, so that $c - 1/(p-1) > 0$, and let $v(x) \geq c$. Then for $n \geq 2$

$$v\Big(\frac{x^n}{n!}\Big) - v(x) \geq (n-1)\Big(v(x) - \frac{1}{p-1}\Big) > 0, \qquad v\Big(\frac{x^n}{n}\Big) - v(x) \geq (n-1)\Big(v(x) - \frac{1}{p-1}\Big) > 0.$$

So both series converge, $v(\exp(x) - 1) = v(x)$ and $v(\log(1+x)) = v(x)$; exp maps $p^n\mathbb{Z}_p$ into $1 + p^n\mathbb{Z}_p$ and log maps $1 + p^n\mathbb{Z}_p$ into $p^n\mathbb{Z}_p$ for $n \geq c$, and both preserve v of the deviation from 0, resp. 1.

The identities $\exp(X+Y) = \exp(X)\exp(Y)$, $\log((1+X)(1+Y)) = \log(1+X) + \log(1+Y)$, $\exp(\log(1+X)) = 1 + X$ and $\log(\exp X) = X$ hold in $\mathbb{Q}[[X, Y]]$. They hold numerically for $v(x), v(y) \geq c$ by Lemma 7.4. Take $\exp(\log(1+x))$: expanding $\sum_m \frac{1}{m!}\big(\sum_n (-1)^{n+1}x^n/n\big)^m$ gives a family of terms $\pm x^N/(n_1 \cdots n_m\, m!)$ with $N = n_1 + \cdots + n_m \geq m$, of valuation

$$\geq Nc - \frac{N-m}{p-1} - \frac{m-1}{p-1} = N\Big(c - \frac{1}{p-1}\Big) + \frac{1}{p-1},$$

and for each N there are finitely many terms; so the family is summable. Grouping by m gives $\exp(\log(1+x))$, and grouping by N gives $\sum_N \alpha_N x^N$ where α_N is the coefficient of X^N in $\exp(\log(1+X)) = 1 + X$. The other three identities are proved in the same way (the terms of $\log(\exp x)$ are $\pm\prod x^{n_i}/(n_i!\, m)$, with the same bound; those of $\log((1+x)(1+y))$ come from $(x + y + xy)^n/n$; those of $\exp(x+y)$ are $x^a y^b/(a!\, b!)$). Hence exp and log are inverse continuous homomorphisms $p^c\mathbb{Z}_p \leftrightarrows 1 + p^c\mathbb{Z}_p$, matching $p^n\mathbb{Z}_p$ and $1 + p^n\mathbb{Z}_p$ for $n \geq c$.

(i) p odd: $1 + p\mathbb{Z}_p \simeq p\mathbb{Z}_p \simeq \mathbb{Z}_p$ $(x \mapsto x/p)$; since $v(\log(1+p)) = 1$, $\log(1+p)$ generates $p\mathbb{Z}_p$ as a $\mathbb{Z}_p$-module, so $1 + p$ generates $1 + p\mathbb{Z}_p$ topologically. With Theorem 7.17(iii) and Theorem 7.8(iii) this gives the structure of $\mathbb{Q}_p^\times$. (ii) $p = 2$: every $u \in \mathbb{Z}_2^\times$ is $\equiv \pm 1 \pmod 4$, so exactly one of $\pm u$ lies in $1 + 4\mathbb{Z}_2$; and $v(\log 5) = v(4) = 2$, so 5 generates. (iii) Reduce modulo p^k: $(\mathbb{Z}/p^k)^\times = \mathbb{Z}_p^\times/(1+p^k\mathbb{Z}_p) \simeq \mu_{p-1} \times \mathbb{Z}_p/p^{k-1}\mathbb{Z}_p$, cyclic for p odd, and $\{\pm 1\} \times \mathbb{Z}_2/2^{k-2}$ for $p = 2$. (iv) The first statement is Theorem 7.17(iii) together with $K^\times = \varpi^{\mathbb{Z}} \times \mathcal{O}^\times$. The map $1 + \varpi^i a \mapsto \bar{a}$ is a homomorphism $U^{(i)} \to (\mathbb{F}_q, +)$ with kernel $U^{(i+1)}$, since $(1+\varpi^i a)(1+\varpi^i b) = 1 + \varpi^i(a+b) + \varpi^{2i}ab$; so $U^{(1)}/U^{(n)}$ is a finite abelian p-group, and $U^{(1)} = \varprojlim_n U^{(1)}/U^{(n)}$ ($U^{(1)}$ is compact and the $U^{(n)}$ form a basis of open neighbourhoods of 1). An abelian pro-p group is a $\mathbb{Z}_p$-module ($u^a = \lim u^{a_k}$ for integers $a_k \to a$; the limit exists because $u^{p^N} \in U^{(n)}$ for N large). For $p \nmid m$, multiplication by m is an automorphism of each finite p-group $U^{(1)}/U^{(n)}$, compatibly in n, hence of $U^{(1)}$. □

Corollary 7.19 (roots of unity). *$\mu(\mathbb{Q}_p) = \mu_{p-1}$ for p odd and $\mu(\mathbb{Q}_2) = \{\pm 1\}$. For K as in Theorem 7.18(iv) and m prime to p, $\mu_m(K) = \mu_{\gcd(m,q-1)}$, and reduction is injective on it. In particular, for primes $\ell \neq p$: $\mu_{\ell^k} \subset \mathbb{Q}_p$ iff $\ell^k \mid p-1$, $\#\mu_{\ell^\infty}(\mathbb{Q}_p) = \ell^{v_\ell(p-1)}$, and $i \in \mathbb{Q}_\ell$ iff $\ell \equiv 1 \pmod 4$ (so $\mathbb{Q}_\ell(i)$ is a field iff $\ell \not\equiv 1 \pmod 4$). Also $\mu_{p^n} \subset \mathbb{Q}_p$ only for $p^n \in \{1, 2\}$.*

Proof. The torsion of $\mathbb{Z} \times \mathbb{Z}/(p-1) \times \mathbb{Z}_p$ is $\mathbb{Z}/(p-1)$, and that of $\mathbb{Z} \times \mathbb{Z}/2 \times \mathbb{Z}_2$ is $\mathbb{Z}/2$. For K: an element of $U^{(1)}$ of order prime to p is trivial by unique divisibility, so $\mu_m(K)$ injects into $\mu_{q-1}(K) \simeq \mathbb{F}_q^\times$, a cyclic group of order $q-1$, whose elements of order dividing m form $\mu_{\gcd(m,q-1)}$. The remaining statements are special cases ($\ell = 2$: $\mu_2 \subset \mathbb{Q}_p$ always; $i \in \mathbb{Q}_\ell$ iff $4 \mid \ell - 1$ for ℓ odd, and $i \notin \mathbb{Q}_2$). □

7.2.3 Powers

Theorem 7.20 (ℓ^k-th powers, $\ell \neq p$). *Let $\ell \neq p$ be primes, $k \geq 1$, and K complete for a discrete valuation with residue field $\mathbb{F}_q$ of characteristic p and uniformiser ϖ (for $K = \mathbb{Q}_p$: $q = p$, $\varpi = p$). Put $v = v_\ell(q-1)$.*

(i) $U^{(1)}$ *is uniquely* ℓ^k*-divisible.*

(ii) $u \in \mathcal{O}_K^\times$ *is an* ℓ^k*-th power in* K *iff its reduction* $\bar{u}$ *is an* ℓ^k*-th power in* $\mathbb{F}_q^\times$*; this holds iff* $\bar{u}^{(q-1)/d} = 1$*, where* $d = \gcd(\ell^k, q-1)$*.*

(iii) $x = \varpi^a u \in K^\times$ *(*u *a unit) is an* ℓ^k*-th power iff* $\ell^k \mid a$ *and* $\bar{u} \in (\mathbb{F}_q^\times)^{\ell^k}$*.*

(iv) There is an exact sequence $1 \to \mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^k} \to K^\times/(K^\times)^{\ell^k} \xrightarrow{v_K} \mathbb{Z}/\ell^k \to 0$*, split by* ϖ*, so*

$$K^\times/(K^\times)^{\ell^k} \simeq \mathbb{Z}/\ell^k \times \mathbb{Z}/\ell^{\min(k,v)}, \qquad \#K^\times/(K^\times)^{\ell^k} = \ell^k \cdot \#\mu_{\ell^k}(K).$$

(v) In the limit, $\widehat{K^\times} := \varprojlim_k K^\times/(K^\times)^{\ell^k}$ *sits in an exact sequence* $0 \to \mathbb{F}_q^\times \otimes \mathbb{Z}_\ell \to \widehat{K^\times} \xrightarrow{v_K} \mathbb{Z}_\ell \to 0$*, split by* ϖ*; so* $\widehat{K^\times} \simeq \mathbb{Z}_\ell \times \mathbb{Z}/\ell^v$*, and* $\mathbb{F}_q^\times \otimes \mathbb{Z}_\ell = \mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^v} \simeq \mu_{\ell^v}(\mathbb{F}_q)$*, via* $y \mapsto y^{(q-1)/\ell^v}$*.*

(vi) ($\ell = 2$*,* $K = \mathbb{Q}_p$*.) For* p *odd,* $\mathbb{Q}_p^\times/(\mathbb{Q}_p^\times)^2$ *has order* 4*, with representatives* $1, u_0, p, u_0 p$ *for a non-square unit* u_0*;* $\mathbb{Q}_2^\times/(\mathbb{Q}_2^\times)^2$ *has order* 8*, with representatives* $\pm 1, \pm 5, \pm 2, \pm 10$*.*

Proof. (i) is Theorem 7.18(iv); alternatively, Theorem 7.12(b) applies to $X^{\ell^k} - u$ at $a_0 = 1$, since ℓ^k is a unit. (ii) Write $u = [\bar{u}]u_1$ with $u_1 \in U^{(1)}$ (Theorem 7.17). If $\bar{u} = \bar{b}^{\ell^k}$, then $[\bar{u}] = [\bar{b}]^{\ell^k}$ and u_1 is an ℓ^k-th power by (i). Conversely, reduce an equation $u = y^{\ell^k}$ (then y is a unit). The last equivalence is the criterion for powers in the cyclic group $\mathbb{F}_q^\times$ (Chapter 2). (iii) If $x = y^{\ell^k}$ then $a = \ell^k v_K(y)$ and $u = (y\varpi^{-v_K(y)})^{\ell^k}$; conversely apply (ii). (iv) By (iii) the kernel of v_K mod ℓ^k is the image of $\mathcal{O}_K^\times$, and $\mathcal{O}_K^\times \cap (K^\times)^{\ell^k} = (\mathcal{O}_K^\times)^{\ell^k}$; by (ii) $\mathcal{O}_K^\times/(\mathcal{O}_K^\times)^{\ell^k} \simeq \mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^k}$, cyclic of order $\gcd(\ell^k, q-1) = \ell^{\min(k,v)} = \#\mu_{\ell^k}(K)$ (Corollary 7.19). (v) The sequences of (iv) form an inverse system of finite groups, and inverse limits of finite groups are exact (Chapter 1). For $k \geq v$ the left term is $\mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^v}$, which is $\mathbb{F}_q^\times \otimes \mathbb{Z}_\ell$; and $y \mapsto y^{(q-1)/\ell^v}$ maps the cyclic group $\mathbb{F}_q^\times$ onto its subgroup of order ℓ^v with kernel $(\mathbb{F}_q^\times)^{\ell^v}$. (vi) For p odd, (iv) with $\ell = 2$ gives order 4. For $p = 2$: $\mathbb{Q}_2^\times = 2^{\mathbb{Z}} \times \{\pm 1\} \times (1 + 4\mathbb{Z}_2)$, and the squares of $1 + 4\mathbb{Z}_2$ form $1 + 8\mathbb{Z}_2$ (Example 7.16(d)), of index 2 with representatives $1, 5$. □

In the paper 7.21. Lemma lem:tamfactor defines $c(u)$ as "the class of the reduction of u in $\mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^v}$" and uses that $v_\ell(c(u)) \geq k$ iff the reduction of u is an ℓ^k-th power in $\mathbb{F}_q^\times$ ($k \leq v$). By Theorem 7.20(ii) this is the same as $u \in (\mathbb{Z}_q^\times)^{\ell^k}$, since $\ell \neq q$. The equivalence fails for $\ell = q$ (for q odd, $1 + q$ is a q-th power in $\mathbb{F}_q$ but not in $\mathbb{Z}_q$, since $1 + q\mathbb{Z}_q \simeq \mathbb{Z}_q$ carries the q-th powers onto $1 + q^2\mathbb{Z}_q$). The group $\varprojlim \mathbb{Q}_q^\times/(\mathbb{Q}_q^\times)^{\ell^k} \simeq \mathbb{Z}_\ell \times \mathbb{Z}/\ell^v$ of (v) is the paper's $H^1(G, \mathbb{Z}_\ell(1))$ (Proposition 7.57), with torsion $\mathbb{F}_q^\times \otimes \mathbb{Z}_\ell \simeq \mathbb{Z}_\ell(1)/(q-1)$.

Example 7.22. (a) $\mathbb{Q}_7^\times/(\mathbb{Q}_7^\times)^3 \simeq \mathbb{Z}/3 \times \mathbb{Z}/3$. The cubes of $\mathbb{F}_7^\times$ are $\{1, 6\}$; so 6 is a cube in $\mathbb{Q}_7$, while 2 is not, 14 is not ($v_7(14) = 1$), and $7^3 \cdot 6$ is.

(b) $\mathbb{Q}_{19}^\times/(\mathbb{Q}_{19}^\times)^9 \simeq \mathbb{Z}/9 \times \mathbb{Z}/9$, as $v_3(18) = 2$. Since 2 generates $\mathbb{F}_{19}^\times$, the classes of 2, $8 = 2^3$ and $-1 = 2^9$ in $\mathbb{F}_{19}^\times/(\mathbb{F}_{19}^\times)^9 \simeq \mathbb{Z}/9$ are 1, 3 and 0, of 3-adic valuations 0, 1 and (by the convention of Lemma lem:tamfactor, $v_\ell(0) = v$) 2.

(c) For the curve `11a1`, $j = -2^{12}31^3/11^5$, and the Tate parameter $q_E = j^{-1} + 744j^{-2} + 750420j^{-3} + \dots$ (Chapter 10) satisfies $v_{11}(q_E) = 5$ and $q_E 11^{-5} \equiv -1 \pmod{11}$ (by hand: $q_E 11^{-5} \equiv (j11^5)^{-1} = -(2^{12}31^3)^{-1}$, with $2^{12} \equiv 4$, $31^3 \equiv 3$, $4 \cdot 3 \equiv 1$; PARI gives $q_E = 10 \cdot 11^5 + 2 \cdot 11^6 + \dots$). The fifth powers of $\mathbb{F}_{11}^\times$ are $\{\pm 1\}$, so $q_E \in (\mathbb{Q}_{11}^\times)^5$.

(d) $\mathbb{Q}_5^\times/(\mathbb{Q}_5^\times)^3 \simeq \mathbb{Z}/3$: every unit of $\mathbb{Z}_5$ is a cube, as $3 \nmid 4$.

7.3 Finite extensions of $\mathbb{Q}_p$

The coefficient rings of the paper ($\mathbb{Z}_\ell[\zeta_3]$, the completions $\mathcal{O}_\lambda$ of rings of integers at primes $\lambda \mid \ell$) and the fields over which the paper's curves acquire good or multiplicative reduction are finite extensions of $\mathbb{Q}_\ell$ or $\mathbb{Q}_q$. This section extends the absolute value to them, defines the ramification index and residue degree, identifies totally ramified extensions with Eisenstein polynomials, compares completions of number fields with the global theory of Chapter 6, and proves that the decomposition group of a prime of $\overline{\mathbb{Q}}$ above p is $G_{\mathbb{Q}_p}$. In the paper these facts are used in Lemma lem:IV ($\mathbb{Z}_3[\zeta_3]$ as a discrete valuation ring, now the ring of integers of $\mathbb{Q}_3(\sqrt{-3})$), in Lemma lem:crit ("The same statements hold with $\mathbb{Z}$ replaced by $\mathbb{Z}_\ell$ and r by its ℓ-part") and Lemma lem:old, and in every local argument at a bad prime q, which is an argument about $G_{\mathbb{Q}_q} \subset G_{\mathbb{Q}}$.

Throughout, K is complete for a discrete valuation with finite residue field, as in Convention 7.1.

Lemma 7.23 (equivalence of norms)**.** *Let K be complete for an absolute value and V a finite-dimensional K-vector space. A* norm *on V is a map $\|\cdot\|\colon V \to \mathbb{R}_{\geq 0}$ with $\|x\| = 0$ iff $x = 0$, $\|ax\| = |a|\|x\|$ and $\|x+y\| \leq \|x\| + \|y\|$. Any two norms $\|\cdot\|_1, \|\cdot\|_2$ on V are equivalent: $c\|x\|_1 \leq \|x\|_2 \leq C\|x\|_1$ for constants $c, C > 0$. In particular V is complete for every norm.*

Proof. Fix a basis $e_1, \dots, e_n$ and the sup norm $\|\sum x_i e_i\|_\infty = \max|x_i|$; it suffices to compare a norm $\|\cdot\|$ with it. Clearly $\|x\| \leq C\|x\|_\infty$ with $C = \sum\|e_i\|$, since $\|\sum x_i e_i\| \leq \sum|x_i|\|e_i\| \leq \max_i|x_i| \cdot \sum_i\|e_i\|$. For the other inequality we argue by induction on n; for $n = 1$, $\|x_1 e_1\| = |x_1|\|e_1\|$, so $c = \|e_1\|$ works. If no $c > 0$ works, there are $v_k = \sum_i x_i^{(k)} e_i$ with $\|v_k\|_\infty = 1$ and $\|v_k\| \to 0$. For each k some coordinate has absolute value 1, and one index occurs for infinitely many k; passing to a subsequence and renumbering, $|x_n^{(k)}| = 1$ for all k. Put $w_k = v_k/x_n^{(k)} = u_k + e_n$ with $u_k \in W = \langle e_1, \dots, e_{n-1}\rangle$. Then $\|w_k\| = \|v_k\| \to 0$, so (u_k) is Cauchy for $\|\cdot\|$ on W (as $\|u_k - u_j\| = \|w_k - w_j\| \leq \|w_k\| + \|w_j\|$), hence for $\|\cdot\|_\infty$ by induction, and converges in the sup norm (as K is complete) to some $u \in W$, hence also for $\|\cdot\|$. Then $\|u + e_n\| = \lim\|w_k\| = 0$, so $e_n = -u \in W$, which is absurd. Completeness follows: a $\|\cdot\|$-Cauchy sequence is $\|\cdot\|_\infty$-Cauchy, and converges coordinatewise. □

Theorem 7.24 (extension of the absolute value)**.** *Let L/K be a finite extension of degree n. Then*

$$|x|_L = |N_{L/K}(x)|^{1/n}$$

is the unique absolute value on L extending $|\cdot|$; it is discrete, L is complete for it, and $\mathcal{O}_L = \{|x|_L \leq 1\}$ is the integral closure of $\mathcal{O}_K$ in L. Consequently every algebraic extension of K (for instance $\overline{\mathbb{Q}}_p$) carries a unique absolute value extending $|\cdot|$; automorphisms over K are isometries, and conjugate elements over K have the same absolute value.

Proof. Let $x \in L$ have minimal polynomial m over K, of degree d; then the norm of x is $N_{L/K}(x) = ((-1)^d m(0))^{n/d}$. We claim: x is integral over $\mathcal{O}_K$ iff $m \in \mathcal{O}_K[X]$ iff $|N_{L/K}(x)| \leq 1$. If x is integral, so are its conjugates in a splitting field, and $m(0)$, a product of them up to sign, is an element of K integral over the integrally closed $\mathcal{O}_K$, so $m(0) \in \mathcal{O}_K$, and $m \in \mathcal{O}_K[X]$ by Corollary 7.15. If $m \in \mathcal{O}_K[X]$, then x is integral (it is a root of the monic m), and $|N_{L/K}(x)| = |m(0)|^{n/d} \leq 1$. Finally, if $|N_{L/K}(x)| \leq 1$, then $|m(0)| \leq 1$, and the monic irreducible

m lies in $\mathcal{O}_K[X]$ by the last statement of Corollary 7.15. So $\{|x|_L \le 1\}$ is the integral closure, a ring. Now $|\cdot|_L$ is multiplicative (the norm is), vanishes only at 0, and extends $|\cdot|$ since $N_{L/K}(x) = x^n$ for $x \in K$. For the ultrametric inequality, let $x, y \in L$ with, say, $|y|_L \le |x|_L$ and $x \neq 0$; then $|x+y|_L = |x|_L|1 + y/x|_L$, so it suffices to show $|1+z|_L \le 1$ when $|z|_L \le 1$; and this holds because z and 1 lie in the integral closure, which is a ring. The values lie in $|K^\times|^{1/n}$, a discrete group. Uniqueness: two extensions are norms on the K-vector space L, hence equivalent by Lemma 7.23: $c|x|_1 \le |x|_2 \le C|x|_1$; applied to x^k this gives $c^{1/k}|x|_1 \le |x|_2 \le C^{1/k}|x|_1$ for all k, so $|x|_1 = |x|_2$. Completeness is Lemma 7.23. An algebraic extension is the union of its finite subextensions, on which the extensions are compatible by uniqueness. If σ is a K-automorphism, $x \mapsto |\sigma x|$ is another extension, hence equals $|x|$; conjugates are exchanged by such automorphisms of a normal closure. □

The field $\overline{\mathbb{Q}}_p$ is not complete; its completion $\mathbb{C}_p$ is algebraically closed, but we shall not need it.

Theorem 7.25 (ramification index and residue degree)**.** *Let L/K be finite of degree n, with normalised valuation v_L and residue field k_L. Put $e = e(L/K) = v_L(\varpi_K) = [|L^\times| : |K^\times|]$ and $f = f(L/K) = [k_L : k_K]$. Let $\alpha_1, \dots, \alpha_f \in \mathcal{O}_L$ lift a basis of k_L over k_K and let ϖ_L be a uniformiser of L. Then $\{\alpha_i \varpi_L^j : 1 \le i \le f,\ 0 \le j < e\}$ is a basis of $\mathcal{O}_L$ over $\mathcal{O}_K$; so $\mathcal{O}_L$ is free of rank n and $ef = n$. Both e and f are multiplicative in towers.*

Proof. First, for $c_1, \dots, c_f \in K$ not all 0, $v_L(\sum_i c_i\alpha_i) = e \min_i v_K(c_i)$: dividing by c_{i_0} with $v_K(c_{i_0})$ minimal, the sum becomes an element of $\mathcal{O}_L$ whose reduction is a nontrivial k_K-combination of the $\bar\alpha_i$, hence a unit. Consequently, for $c_{ij} \in K$ not all 0,

$$v_L\Big(\sum_{i,j} c_{ij}\alpha_i\varpi_L^j\Big) = \min_j\Big(e \min_i v_K(c_{ij}) + j\Big),$$

because the inner sums $s_j = \sum_i c_{ij}\alpha_i\varpi_L^j$ have valuations in distinct classes modulo e ($0 \le j < e$), so the minimum is attained once. Hence the $\alpha_i\varpi_L^j$ are linearly independent over K (in particular $f \le n$ and $e \le n$ are finite), and an element of their $\mathcal{O}_K$-span M that lies in $\varpi_K^k\mathcal{O}_L$ has all coefficients in $\varpi_K^k\mathcal{O}_K$ (if $e\,v_K(c_{ij}) + j \ge ek$ with $j < e$, then $v_K(c_{ij}) \ge k$). Next, $\mathcal{O}_L = M + \varpi_K\mathcal{O}_L$: the quotient $\mathcal{O}_L/\varpi_K\mathcal{O}_L = \mathcal{O}_L/\mathfrak{m}_L^e$ is filtered by the $\mathfrak{m}_L^j/\mathfrak{m}_L^{j+1}$, $0 \le j < e$, each a one-dimensional k_L-space spanned by ϖ_L^j, hence a k_K-space with basis the $\bar\alpha_i\varpi_L^j$. Iterating, $\mathcal{O}_L = M + \varpi_K^k\mathcal{O}_L$ for all k. Given $x \in \mathcal{O}_L$, write $x = m_k + \varpi_K^k y_k$ with $m_k \in M$; then $m_{k+1} - m_k \in M \cap \varpi_K^k\mathcal{O}_L$ has coefficients in $\varpi_K^k\mathcal{O}_K$, so the coefficients converge in the complete $\mathcal{O}_K$, and $m_k \to m \in M$ with $x - m \in \bigcap_k \varpi_K^k\mathcal{O}_L = 0$. So $\mathcal{O}_L = M$ is free with the stated basis. Every $x \in L$ has $\varpi_K^k x \in \mathcal{O}_L$ for k large, so the basis is also a K-basis of L, and $ef = n$. Multiplicativity in towers $K \subseteq L \subseteq M$: writing $\varpi_K = \varpi_L^{e(L/K)}u$ with $u \in \mathcal{O}_L^\times$ and applying v_M, which is $e(M/L)$ on ϖ_L and 0 on units, gives $e(M/K) = e(M/L)e(L/K)$; and $[k_M : k_K] = [k_M : k_L][k_L : k_K]$ is the tower law for the residue fields. □

The two numbers measure different things: e counts how much the value group grows, f how much the residue field grows. In the two extreme cases one of them is 1: $\mathbb{Q}_3(\sqrt{-3})$ has $e = 2$, $f = 1$ (Proposition 7.28(ii)), and $\mathbb{Q}_2(\sqrt{5})$ has $e = 1$, $f = 2$ (Proposition 7.60(iii)); the next definition names these cases.

Definition 7.26. A finite extension L/K is *unramified* if $e(L/K) = 1$, *totally ramified* if $f(L/K) = 1$, *tamely ramified* if $p \nmid e(L/K)$ and *wildly ramified* if $p \mid e(L/K)$, p the residue

characteristic. (Residue fields are finite, hence perfect, so no separability condition on k_L/k_K is needed.) For K a completion of a number field, this is the global notion of Chapter 6 for the one prime above $\mathfrak{p}$ in the completion (Theorem 7.30).

Theorem 7.27 (Eisenstein polynomials)**.** *An extension L/K is totally ramified of degree e iff $L = K(\pi)$ for a root π of an Eisenstein polynomial $X^e + c_{e-1}X^{e-1} + \cdots + c_0$ ($c_i \in \mathfrak{m}_K$, $c_0 \notin \mathfrak{m}_K^2$). Then the polynomial is irreducible, π is a uniformiser of L and $\mathcal{O}_L = \mathcal{O}_K[\pi]$. Conversely the minimal polynomial over K of any uniformiser of a totally ramified L is Eisenstein.*

Proof. Let π be a root, $L = K(\pi)$, $d = [L : K] \le e$, and $w = v_L$. As π is integral, $w(\pi) \ge 0$; if $w(\pi) = 0$, then $\pi^e = -\sum_{i<e} c_i\pi^i$ has positive valuation, which is absurd; so $w(\pi) \ge 1$. On K, $w = e(L/K)\, v_K$; as $v_K(c_0) = 1$ and $v_K(c_i) \ge 1$, we get $w(c_0) = e(L/K)$ and $w(c_i\pi^i) \ge e(L/K) + i > e(L/K)$ for $i \ge 1$. In $\pi^e = -c_0 - \sum_{1\le i<e} c_i\pi^i$ the term c_0 therefore has strictly the smallest valuation, so $ew(\pi) = w(\pi^e) = e(L/K) \le d \le e$ (Proposition 7.3(ii) and Theorem 7.25). Hence $w(\pi) = 1$, $e(L/K) = d = e$, the polynomial is irreducible and L/K is totally ramified; and by Theorem 7.25 (with $f = 1$, $\alpha_1 = 1$) $1, \pi, \dots, \pi^{e-1}$ is a basis of $\mathcal{O}_L$. Conversely, if L/K is totally ramified of degree e and π is a uniformiser, $1, \pi, \dots, \pi^{e-1}$ is a basis (Theorem 7.25), so $L = K(\pi)$ has degree e. The conjugates of π in a normal closure have absolute value $|\pi| < 1$ (Theorem 7.24), so the non-leading coefficients of the minimal polynomial, which are sums of products of conjugates, lie in $\mathfrak{m}_K$; and $v_K(c_0) = v_K(N_{L/K}\pi) = v_L(\pi) = 1$, because $|N_{L/K}x| = |x|_L^e$ and $v_L = e\, v_K$ on K. □

Proposition 7.28 (examples of totally ramified extensions)**.** *(i) For $n \ge 1$, $\Phi_{p^n}(X+1)$ is Eisenstein, so $\mathbb{Q}_p(\zeta_{p^n})/\mathbb{Q}_p$ is totally ramified of degree $\varphi(p^n)$, with uniformiser $1-\zeta_{p^n}$, ring of integers $\mathbb{Z}_p[\zeta_{p^n}]$, and $\mathrm{Gal}(\mathbb{Q}_p(\zeta_{p^n})/\mathbb{Q}_p) \simeq (\mathbb{Z}/p^n)^\times$; the residue field is $\mathbb{F}_p$, so the whole group acts trivially on it (it is all inertia, in the language of Section 7.5).*

(ii) $\mathbb{Q}_3(\zeta_3) = \mathbb{Q}_3(\sqrt{-3})$ is a totally ramified quadratic extension, tamely ramified ($3 \nmid 2$). Its ring of integers is $\mathbb{Z}_3[\zeta_3] \simeq \mathbb{Z}_3[X]/(X^2+X+1) \simeq \mathbb{Z}_3 \otimes_{\mathbb{Z}} \mathbb{Z}[\zeta_3]$, a discrete valuation ring with uniformiser $\pi = 1 - \zeta_3$, residue field $\mathbb{F}_3$ and $\pi^2 = -3\zeta_3$; it is the π-adic completion of $\mathbb{Z}[\zeta_3]$.

(iii) For $m \ge 1$, $X^m - p$ is Eisenstein, so $\mathbb{Q}_p(p^{1/m})/\mathbb{Q}_p$ is totally ramified of degree m.

(iv) For p odd and $p^* = (-1)^{(p-1)/2}p$, $\mathbb{Q}_p(\sqrt{p^*})/\mathbb{Q}_p$ is totally and tamely ramified of degree 2.

Proof. (i) $\Phi_{p^n}(X) = \sum_{i=0}^{p-1} X^{ip^{n-1}}$, so modulo p, $\Phi_{p^n}(X+1) = ((X+1)^{p^n}-1)/((X+1)^{p^{n-1}}-1) \equiv X^{p^n}/X^{p^{n-1}} = X^{\varphi(p^n)}$, and its constant term is $\Phi_{p^n}(1) = p$. The root $\zeta_{p^n} - 1$ is then a uniformiser and $\mathcal{O} = \mathbb{Z}_p[\zeta_{p^n} - 1]$ by Theorem 7.27. The Galois group embeds in $(\mathbb{Z}/p^n)^\times$ (Chapter 5) and has order $\varphi(p^n)$; as $f = 1$ the residue field is $\mathbb{F}_p$, on which every automorphism is trivial (so, once Section 7.5 defines inertia, the whole group is the inertia group, Proposition 7.42(i)). (ii) $\Phi_3(X+1) = (X+1)^2 + (X+1) + 1 = X^2 + 3X + 3$ is Eisenstein at 3, and $\sqrt{-3} = 2\zeta_3 + 1$, because $(2\zeta_3+1)^2 = 4(\zeta_3^2 + \zeta_3) + 1 = -4 + 1 = -3$. So $\mathbb{Q}_3(\zeta_3) = \mathbb{Q}_3(\sqrt{-3})$, of degree 2, X^2+X+1 is irreducible over $\mathbb{Q}_3$, the ring of integers is $\mathbb{Z}_3[\zeta_3 - 1] = \mathbb{Z}_3[\zeta_3] \simeq \mathbb{Z}_3[X]/(X^2+X+1)$, with uniformiser $\zeta_3 - 1 = -\pi$; and $\pi^2 = 1 - 2\zeta_3 + \zeta_3^2 = -3\zeta_3$. Right exactness of $\otimes$ gives $\mathbb{Z}_3 \otimes \mathbb{Z}[\zeta_3] \simeq \mathbb{Z}_3[X]/(X^2+X+1)$, and Theorem 7.30(ii) identifies this with the π-adic completion of $\mathbb{Z}[\zeta_3]$, (π) being the only prime above 3. (iii), (iv) are Theorem 7.27: all non-leading coefficients of $X^m - p$ and of $X^2 - p^*$ are divisible by p, and the constant terms $-p$ and $-p^* = \mp p$ are not divisible by p^2. In (iv) the ramification index 2 is prime to the odd p, so the extension is tame. □

In the paper 7.29. The paragraph after Lemma lem:IV says that T_3E "is a torsion-free module of $\mathbb{Z}_3$-rank 2 over the discrete valuation ring $\mathbb{Z}_3[X]/(X^2+X+1) \simeq \mathbb{Z}_3[\zeta_3]$, with X acting as σ, hence free of rank one over it", and the proof of Lemma lem:tamadd uses the same ring. Chapter 6 proved that this ring is a discrete valuation ring and equals $\mathbb{Z}_3 \otimes \mathbb{Z}[\zeta_3]$; Proposition 7.28(ii) identifies it as the ring of integers of $\mathbb{Q}_3(\sqrt{-3})$, a discrete valuation ring with uniformiser $\pi = 1-\zeta_3$ and residue field $\mathbb{F}_3$, and as the completion of $\mathbb{Z}[\zeta_3]$ at $(1-\zeta_3)$, which is what Chapter 6 stated with a pointer here.

7.3.1 Completions of number fields

Theorem 7.30 (completions of a number field)**.** *Let F be a number field and p a prime with $p\mathcal{O}_F = \prod_{\mathfrak{p}\mid p} \mathfrak{p}^{e_\mathfrak{p}}$ and residue degrees $f_\mathfrak{p}$ (Chapter 6).*

(i) The absolute values on F extending $|\cdot|_p$ are exactly the maps $|x|_\mathfrak{p} = p^{-v_\mathfrak{p}(x)/e_\mathfrak{p}}$, one for each $\mathfrak{p} \mid p$, and distinct primes give inequivalent absolute values.

(ii) The completion $F_\mathfrak{p}$ is a finite extension of $\mathbb{Q}_p$ with $e(F_\mathfrak{p}/\mathbb{Q}_p) = e_\mathfrak{p}$ and $f(F_\mathfrak{p}/\mathbb{Q}_p) = f_\mathfrak{p}$, and its ring of integers is $\mathcal{O}_{F_\mathfrak{p}} = \varprojlim_n \mathcal{O}_F/\mathfrak{p}^n$.

(iii) $\mathcal{O}_F \otimes_\mathbb{Z} \mathbb{Z}_p \simeq \prod_{\mathfrak{p}\mid p} \mathcal{O}_{F_\mathfrak{p}}$ and $F \otimes_\mathbb{Q} \mathbb{Q}_p \simeq \prod_{\mathfrak{p}\mid p} F_\mathfrak{p}$; each $\mathcal{O}_{F_\mathfrak{p}}$ is free over $\mathbb{Z}_p$ of rank $e_\mathfrak{p}f_\mathfrak{p}$, and $\sum_\mathfrak{p} e_\mathfrak{p}f_\mathfrak{p} = [F:\mathbb{Q}]$.

Proof. (i) Let $|\cdot|$ extend $|\cdot|_p$. It is nonarchimedean (Proposition 7.3(i)). Every $x \in \mathcal{O}_F$ satisfies a monic equation over $\mathbb{Z}$, and $|x| \le 1$ follows as in the proof of Theorem 7.24 (if $|x| > 1$ the leading term of the equation dominates). So $\mathfrak{p} = \{x \in \mathcal{O}_F : |x| < 1\}$ is a prime ideal containing p, and elements of $\mathcal{O}_F \setminus \mathfrak{p}$ have absolute value 1; hence the valuation ring of $|\cdot|$ contains the localisation $\mathcal{O}_{F,\mathfrak{p}}$, a discrete valuation ring (Chapter 6). A ring strictly between a discrete valuation ring and its fraction field contains ϖ^{-1} and is the whole field; so the valuation ring is $\mathcal{O}_{F,\mathfrak{p}}$ and $|x| = c^{v_\mathfrak{p}(x)}$; the normalisation $|p| = p^{-1}$ and $v_\mathfrak{p}(p) = e_\mathfrak{p}$ give $c = p^{-1/e_\mathfrak{p}}$. Different primes give different valuation rings, hence inequivalent absolute values. (ii) By Theorem 7.6, $\mathcal{O}_{F_\mathfrak{p}} = \varprojlim \mathcal{O}_{F,\mathfrak{p}}/\mathfrak{p}^n = \varprojlim \mathcal{O}_F/\mathfrak{p}^n$, with residue field $\mathcal{O}_F/\mathfrak{p}$ and $v_\mathfrak{p}(p) = e_\mathfrak{p}$; finiteness over $\mathbb{Q}_p$ follows from (iii). (iii) As $\mathcal{O}_F \simeq \mathbb{Z}^n$, $\mathcal{O}_F \otimes \mathbb{Z}_p = \varprojlim_k \mathcal{O}_F/p^k\mathcal{O}_F$, and by the Chinese remainder theorem $\mathcal{O}_F/p^k\mathcal{O}_F \simeq \prod_\mathfrak{p} \mathcal{O}_F/\mathfrak{p}^{ke_\mathfrak{p}}$ compatibly in k; the limit is $\prod_\mathfrak{p} \mathcal{O}_{F_\mathfrak{p}}$. Each factor is a direct summand of the free module $\mathbb{Z}_p^n$, so it is finitely generated and torsion free over the discrete valuation ring $\mathbb{Z}_p$, hence free (Chapter 3); its rank is $e_\mathfrak{p}f_\mathfrak{p}$ by Theorem 7.25, and the ranks add up to n. Inverting p gives the statement for $F \otimes \mathbb{Q}_p$. □

For example $\mathbb{Z}[\zeta_3] \otimes \mathbb{Z}_3 = \mathbb{Z}_3[\zeta_3]$ (ramified), $\mathbb{Z}[\zeta_3] \otimes \mathbb{Z}_7 \simeq \mathbb{Z}_7 \times \mathbb{Z}_7$ (split, Example 7.16(c)), and $\mathbb{Z}[\zeta_3] \otimes \mathbb{Z}_2$ is the ring of integers of the unramified quadratic extension of $\mathbb{Q}_2$ (inert). In each case $\mathbb{Z}[\zeta_3] \otimes \mathbb{Z}_p = \mathbb{Z}_p[X]/(X^2+X+1)$, and the three behaviours are read off from the reduction of X^2+X+1 modulo p: it is $(X-1)^2$ for $p=3$ (one prime, $e=2$, $f=1$), it has the two distinct roots 2, 4 for $p=7$ (two primes, $e=f=1$), and it is irreducible for $p=2$, having no root in $\mathbb{F}_2$ (one prime, $e=1$, $f=2$, by Example 7.16(g)). In all three, $\sum e_\mathfrak{p}f_\mathfrak{p} = 2$, as (iii) requires. For the coefficient field of a newform and a prime $\lambda \mid \ell$ the theorem gives the complete discrete valuation ring $\mathcal{O}_\lambda$ used in Chapters 13 and 15. This is the result that Chapter 6 stated and deferred here.

Lemma 7.31 (Krasner)**.** *Let $\alpha \in \overline{K}$ have distinct conjugates $\alpha = \alpha_1, \alpha_2, \dots, \alpha_d$ over K.*

(i) If $\beta \in \overline{K}$ satisfies $|\beta - \alpha| < |\alpha - \alpha_i|$ for $2 \le i \le d$, then $K(\alpha) \subseteq K(\beta)$.

(ii) Let f be the minimal polynomial of α. There is $\delta > 0$ such that every monic $g \in K[X]$ of degree d whose coefficients differ from those of f by less than δ has a root β with $K(\beta) = K(\alpha)$.

Proof. (i) Let $\sigma \in \mathrm{Gal}(\overline{K}/K(\beta))$. Since σ is an isometry (Theorem 7.24), $|\sigma\alpha - \beta| = |\sigma(\alpha - \beta)| = |\alpha - \beta|$, so $|\sigma\alpha - \alpha| \le \max(|\sigma\alpha - \beta|, |\beta - \alpha|) = |\alpha - \beta| < |\alpha - \alpha_i|$ for $i \ge 2$; as $\sigma\alpha$ is a conjugate, $\sigma\alpha = \alpha$. So α is fixed by $\mathrm{Gal}(\overline{K}/K(\beta))$ and lies in $K(\beta)$ (characteristic 0). (ii) If the coefficients of $g - f$ are smaller than δ, then $|g(\alpha)| = |g(\alpha) - f(\alpha)| < \delta \max(1, |\alpha|)^d$, because $g - f = \sum_{i<d} b_i X^i$ with $|b_i| < \delta$ and each $|b_i \alpha^i|$ is at most $|b_i| \max(1, |\alpha|)^d$. Writing $g = \prod_{j=1}^{d}(X - \beta_j)$ over $\overline{K}$ we have $|g(\alpha)| = \prod_j |\alpha - \beta_j|$, so the smallest factor satisfies $|\alpha - \beta_j| \le |g(\alpha)|^{1/d} < \left(\delta \max(1, |\alpha|)^d\right)^{1/d}$, which is less than $\min_{i \ge 2} |\alpha - \alpha_i|$ once δ is small enough. By (i), $K(\alpha) \subseteq K(\beta_j)$, and $[K(\beta_j) : K] \le d$ gives equality. □

(Here $\overline{K}$ denotes $\overline{\mathbb{Q}}_p$, an algebraic closure of K.)

Proposition 7.32 (decomposition groups are local Galois groups)**.** *(i) Let L/F be a finite Galois extension of number fields and $\mathfrak{P} \mid \mathfrak{p}$ primes. Then $L_{\mathfrak{P}} = L \cdot F_{\mathfrak{p}}$, the extension $L_{\mathfrak{P}}/F_{\mathfrak{p}}$ is Galois, and restriction to L is an isomorphism $\mathrm{Gal}(L_{\mathfrak{P}}/F_{\mathfrak{p}}) \to D_{\mathfrak{P}}$, carrying the inertia subgroup onto $I_{\mathfrak{P}}$ and Frobenius elements to Frobenius elements.*

(ii) Let $\iota \colon \overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_p$ be an embedding and $\bar{\mathfrak{P}} = \{x \in \bar{\mathbb{Z}} : |\iota x|_p < 1\}$ the prime of $\bar{\mathbb{Z}}$ it defines. Then $\sigma \mapsto \iota^{-1}\sigma\iota$ is an isomorphism of profinite groups $G_{\mathbb{Q}_p} \to D_{\bar{\mathfrak{P}}} \subseteq G_{\mathbb{Q}}$, carrying I_p onto $I_{\bar{\mathfrak{P}}}$ and arithmetic Frobenius lifts to Frobenius elements. Another embedding $\iota \circ \tau$ ($\tau \in G_{\mathbb{Q}}$) composes this map with conjugation by τ^{-1}.

(iii) Hence for a continuous representation ρ of $G_{\mathbb{Q}}$ the restriction $\rho|_{G_{\mathbb{Q}_p}}$, the image $\rho(I_p)$, the invariants V^{I_p} and, if ρ is unramified at p, $\rho(\mathrm{Frob}_p)$, are well defined up to conjugation.

Proof. (i) The closure of F in $L_{\mathfrak{P}}$ is a completion of F for $|\cdot|_{\mathfrak{p}}$ (up to equivalence, by Theorem 7.30(i)), so $F_{\mathfrak{p}} \subseteq L_{\mathfrak{P}}$. The compositum $LF_{\mathfrak{p}}$ is finite over $F_{\mathfrak{p}}$, hence complete (Theorem 7.24) and closed, and contains the dense subfield L; so $L_{\mathfrak{P}} = LF_{\mathfrak{p}}$. Write $L = F(\theta)$; the minimal polynomial g of θ splits in L, and $L_{\mathfrak{P}} = F_{\mathfrak{p}}(\theta)$ is generated by roots of g, so it is a splitting field of g over $F_{\mathfrak{p}}$, hence Galois. An element τ of $\mathrm{Gal}(L_{\mathfrak{P}}/F_{\mathfrak{p}})$ permutes the roots of g, so maps L to L; it is an isometry, so $\tau|_L$ preserves $\mathfrak{P} = \{x \in \mathcal{O}_L : |x| < 1\}$, i.e. $\tau|_L \in D_{\mathfrak{P}}$; and τ is determined by $\tau|_L$ by continuity. Conversely, for $\sigma \in D_{\mathfrak{P}}$, $x \mapsto |\sigma x|_{\mathfrak{P}}$ is the absolute value of $\sigma^{-1}\mathfrak{P} = \mathfrak{P}$, so σ is an isometry of L and extends by continuity to an automorphism of $L_{\mathfrak{P}}$ over $F_{\mathfrak{p}}$. The residue fields of L at $\mathfrak{P}$ and of $L_{\mathfrak{P}}$ coincide (Theorem 7.6(ii)), compatibly with the actions; so inertia corresponds to inertia and Frobenius to Frobenius. (ii) $\iota(\overline{\mathbb{Q}})$ is the set of elements of $\overline{\mathbb{Q}}_p$ algebraic over $\mathbb{Q}$, so it is stable under $G_{\mathbb{Q}_p}$, and $\sigma \mapsto \iota^{-1}\sigma\iota$ is a continuous homomorphism into $G_{\mathbb{Q}}$, with image in $D_{\bar{\mathfrak{P}}}$ since σ is an isometry. It is injective: given $\alpha \in \overline{\mathbb{Q}}_p$ with minimal polynomial f over $\mathbb{Q}_p$, choose $g \in \mathbb{Q}[X]$ monic, with coefficients close to those of f ($\mathbb{Q}$ is dense in $\mathbb{Q}_p$); by Lemma 7.31(ii) some root β of g has $\mathbb{Q}_p(\beta) = \mathbb{Q}_p(\alpha)$, and $\beta \in \iota(\overline{\mathbb{Q}})$. So $\overline{\mathbb{Q}}_p$ is generated over $\mathbb{Q}_p$ by $\iota(\overline{\mathbb{Q}})$, and an element of $G_{\mathbb{Q}_p}$ trivial on $\iota(\overline{\mathbb{Q}})$ is trivial. It is surjective: for each finite Galois $L/\mathbb{Q}$, with $\mathfrak{P}_L$ the prime below $\bar{\mathfrak{P}}$, $G_{\mathbb{Q}_p}$ maps onto $\mathrm{Gal}(\iota(L)\mathbb{Q}_p/\mathbb{Q}_p)$, which (i) identifies with $D_{\mathfrak{P}_L}$; so the image is dense in $D_{\bar{\mathfrak{P}}} = \varprojlim D_{\mathfrak{P}_L}$ (Chapter 6), and closed, being compact. A continuous bijection of compact Hausdorff groups is a homeomorphism. Inertia and Frobenius correspond at every finite level by (i), hence in the limit. Finally $(\iota\tau)^{-1}\sigma(\iota\tau) = \tau^{-1}(\iota^{-1}\sigma\iota)\tau$. (iii) follows, since the primes above p are conjugate (Chapter 6). □

From now on a decomposition group at p is identified with $G_{\mathbb{Q}_p}$ in this way, and we speak of $\rho|_{G_{\mathbb{Q}_p}}$ and $\rho(I_p)$; this is the statement $D_p \simeq G_{\mathbb{Q}_p}$ that Chapter 6 deferred here.

Proposition 7.33 (tame totally ramified extensions)**.** *Let L/K be totally ramified of degree e with $p \nmid e$. Then $L = K(\alpha)$ with $\alpha^e = \varpi$ for some uniformiser ϖ of K. The extension is Galois iff $\mu_e \subset K$, that is iff $e \mid q-1$; then $\mathrm{Gal}(L/K) \to \mu_e$, $\sigma \mapsto \sigma(\alpha)/\alpha$, is an isomorphism, and $\mathrm{Gal}(L/K)$ is cyclic.*

Proof. Let π_L be a uniformiser of L; then $\pi_L^e = \varpi_K w$ with $w \in \mathcal{O}_L^\times$. As $k_L = k_K$, choose $w_0 \in \mathcal{O}_K^\times$ with the same reduction as w; then $w_1 = w/w_0 \in U_L^{(1)}$, which is uniquely e-divisible (Theorem 7.18(iv)). So $\alpha = \pi_L w_1^{-1/e} \in L$ is a uniformiser of L with $\alpha^e = \varpi_K w_0 =: \varpi$, a uniformiser of K. By Theorem 7.27, $[K(\alpha):K] = e = [L:K]$, so $L = K(\alpha)$. The conjugates of α are the $\zeta\alpha$, $\zeta \in \mu_e$. If L/K is Galois they all lie in L, so $\mu_e \subset L$, and then $e \mid \#k_L^\times = q-1$ (Corollary 7.19) and $\mu_e \subset K$. Conversely, if $\mu_e \subset K$, L is the splitting field of $X^e - \varpi$, and $\sigma \mapsto \sigma(\alpha)/\alpha$ is an injective homomorphism into μ_e (as σ fixes μ_e) between groups of order e. □

7.4 Unramified extensions, $\mathbb{Q}_p^{\mathrm{ur}}$ and Frobenius

The unramified extensions of a local field are generated by roots of unity of order prime to p, are cyclic, and are classified by their residue fields; their union K^{ur} has Galois group $\hat{\mathbb{Z}}$, generated by the Frobenius. This is where the paper's Frobenius lives, and where its two conventions (arithmetic and geometric) must be fixed once and for all (Convention 7.37). The paper uses the section in Lemmas lem:tamagawa-exp and lem:tamfactor ("Over the unramified quadratic extension of $\mathbb{Q}_q$ (which does not change the inertia group) E is a Tate curve"; Kummer theory over $\mathbb{Q}_q^{\mathrm{ur}}$, whose units are ℓ^t-th powers), in Lemma lem:twist(i) (invariance under unramified base change), and in Section 1.1, where Frob_p and its inverse appear.

Theorem 7.34 (unramified extensions)**.** *Let K have residue field $\mathbb{F}_q$.*

(i) For each $f \geq 1$ there is exactly one unramified extension K_f of K of degree f inside $\overline{\mathbb{Q}}_p$, namely $K_f = K(\mu_{q^f-1})$.

(ii) K_f/K is Galois, and reduction is an isomorphism $\mathrm{Gal}(K_f/K) \to \mathrm{Gal}(\mathbb{F}_{q^f}/\mathbb{F}_q)$. So $\mathrm{Gal}(K_f/K)$ is cyclic of order f, generated by the unique $\mathrm{Frob}_{K_f/K}$ with $\mathrm{Frob}(x) \equiv x^q \pmod{\mathfrak{m}_{K_f}}$ for all $x \in \mathcal{O}_{K_f}$; on μ_{q^f-1} it is $\zeta \mapsto \zeta^q$.

(iii) A finite L/K is unramified iff $L = K_f$ for some f. Composita and subextensions of unramified extensions are unramified. Every finite L/K has a largest unramified subextension L_0; $L_0 = K_{f(L/K)}$ and L/L_0 is totally ramified.

(iv) If L/K is unramified and $\alpha \in \mathcal{O}_L$ reduces to a generator of k_L over k_K, then $L = K(\alpha)$.

Proof. (i) Let $\zeta \in \overline{\mathbb{Q}}_p$ be a primitive (q^f-1)-th root of unity and $L = K(\zeta)$. Reduction is injective on roots of unity of order prime to p (Corollary 7.19, applied in L), so $\bar{\zeta}$ has order q^f-1 and generates $\mathbb{F}_{q^f}$ over $\mathbb{F}_q$; hence $f(L/K) \geq f$. The minimal polynomial g of ζ over K lies in $\mathcal{O}_K[X]$ (Corollary 7.15) and divides $X^{q^f-1}-1$, so $\bar{g}$ divides the separable polynomial $X^{q^f-1}-1$ and is separable. Let $\bar{h}$ be the minimal polynomial of $\bar{\zeta}$ over $\mathbb{F}_q$, of degree f; it divides $\bar{g}$. If $\bar{g} \neq \bar{h}$, then $\bar{g} = \bar{h}\bar{r}$ with $\bar{h}$, $\bar{r}$ coprime, and Theorem 7.14 would factor g. So $\bar{g} = \bar{h}$, $[L:K] = f \leq f(L/K)$, and therefore $f(L/K) = f$, $e(L/K) = 1$. Uniqueness: if L'/K

is unramified of degree f, then $k_{L'} = \mathbb{F}_{q^f}$, and the Teichmüller lifts (Theorem 7.17, applied in L') give $\mu_{q^f-1} \subset L'$; so $K_f \subseteq L'$, and the degrees agree. (ii) K_f is the splitting field of $X^{q^f-1} - 1$, so it is Galois. Every $\sigma \in \mathrm{Gal}(K_f/K)$ is an isometry, preserves $\mathcal{O}_{K_f}$ and $\mathfrak{m}_{K_f}$, and induces an automorphism $\bar\sigma$ of $\mathbb{F}_{q^f}$ over $\mathbb{F}_q$. If $\bar\sigma = 1$, then σ fixes μ_{q^f-1} (by injectivity of reduction on it), so $\sigma = 1$. Both groups have order f, so $\sigma \mapsto \bar\sigma$ is an isomorphism, and Frob is the preimage of $x \mapsto x^q$; it maps $\zeta \in \mu_{q^f-1}$ to the root of unity reducing to $\bar\zeta^q$, which is ζ^q. (iii) If L is unramified with $f(L/K) = f$, the argument for uniqueness in (i) shows $L = K_f$. Subextensions are unramified since e is multiplicative; and $K_f, K_{f'} \subseteq K_{ff'}$, so composita are unramified. For any finite L, the Teichmüller lifts give $\mu_{q^{f(L/K)}-1} \subset L$, so $K_{f(L/K)} \subseteq L$; if $K_{f'} \subseteq L$ then $\mathbb{F}_{q^{f'}} \subseteq k_L$, so $f' \mid f(L/K)$ and $\mu_{q^{f'}-1} \subseteq \mu_{q^{f(L/K)}-1}$; hence $L_0 = K_{f(L/K)}$, and $f(L/L_0) = 1$. (iv) Let $f = [L : K] = f(L/K)$. The residue field of $K(\alpha)$ contains $\bar\alpha$, hence $k_K(\bar\alpha) = k_L$, so $[K(\alpha) : K] \geq f(K(\alpha)/K) \geq [k_K(\bar\alpha) : k_K] = f = [L : K]$ (the first inequality is $ef = n$); as $K(\alpha) \subseteq L$, equality holds and $K(\alpha) = L$. □

Definition 7.35 (maximal unramified extension)**.** $K^{\mathrm{ur}} = \bigcup_{f\geq 1} K_f \subseteq \overline{\mathbb{Q}}_p$. Equivalently $K^{\mathrm{ur}} = K(\mu_m : p \nmid m)$, since $\mu_m \subset K_f$ when $m \mid q^f - 1$, which holds for f the order of q modulo m. For $K = \mathbb{Q}_p$ we write $\mathbb{Q}_p^{\mathrm{ur}}$.

The point of passing to K^{ur} is that it removes the residue field from the picture: in K^{ur} every unit is an m-th power for every m prime to p (Proposition 7.36(iv) below), so the only obstruction left to extracting roots is the valuation, and what remains of the Galois group is inertia. For example $\mathbb{Q}_7^{\mathrm{ur}}$ contains $\sqrt{3}$, since 3 is not a square modulo 7 but is one in $\mathbb{F}_{49}$, so $\mathbb{Q}_7(\sqrt{3})$ is the quadratic unramified extension K_2 of $\mathbb{Q}_7$; and $\mathbb{Q}_2^{\mathrm{ur}}$ contains ζ_3, with $f = 2$ the order of 2 modulo 3, so $\mathbb{Q}_2(\zeta_3) = \mathbb{Q}_2(\sqrt{-3})$ is the unramified quadratic extension of $\mathbb{Q}_2$ (Proposition 7.60(iii)).

Proposition 7.36. *(i) The residue field of K^{ur} is $\overline{\mathbb{F}}_q$, and restriction gives isomorphisms $\mathrm{Gal}(K^{\mathrm{ur}}/K) \simeq \varprojlim_f \mathrm{Gal}(K_f/K) \simeq \mathrm{Gal}(\overline{\mathbb{F}}_q/\mathbb{F}_q) \simeq \hat{\mathbb{Z}}$, topologically generated by the arithmetic Frobenius.*

(ii) The absolute value of K^{ur} is discrete with the same value group as K, and ϖ_K is a uniformiser; but K^{ur} is not complete.

(iii) Hensel's lemma (Theorem 7.12) holds for polynomials over $\mathcal{O}_{K^{\mathrm{ur}}}$.

(iv) For every m prime to p: $\mu_m \subset K^{\mathrm{ur}}$; every unit of $\mathcal{O}_{K^{\mathrm{ur}}}$ is an m-th power in K^{ur}; and $x \in (K^{\mathrm{ur}})^\times$ is an m-th power in K^{ur} iff $m \mid v_K(x)$. In particular $\mu_{\ell^\infty} \subset \mathbb{Q}_q^{\mathrm{ur}}$ for every prime $\ell \neq q$.

Proof. (i) The residue field is $\bigcup_f \mathbb{F}_{q^f} = \overline{\mathbb{F}}_q$. Restriction $\mathrm{Gal}(K^{\mathrm{ur}}/K) \to \varprojlim \mathrm{Gal}(K_f/K)$ is an isomorphism by infinite Galois theory (Chapter 5), and the isomorphisms of Theorem 7.34(ii) are compatible; $\mathrm{Gal}(\overline{\mathbb{F}}_q/\mathbb{F}_q) \simeq \hat{\mathbb{Z}}$ with generator $x \mapsto x^q$ (Chapter 5). (ii) Each K_f is unramified, so has the value group of K. Not complete: choose $\omega_n \in \mu_{q^{n!}-1}$ whose reduction generates $\mathbb{F}_{q^{n!}}$, and let $x = \sum_n \omega_n \varpi_K^n$ in the completion. If x lay in some K_f, its expansion with Teichmüller digits in K_f (obtained as in Proposition 7.10, the digit of $y \in \mathcal{O}_{K_f}$ being $[\bar y]$) would be the expansion above, by uniqueness of digits; but $\omega_n \notin K_f$ once $n! \nmid f$. (iii) The coefficients of f and the approximate root a_0 lie in some K_f, which is complete; the Newton sequence stays in K_f, and so does the root. (iv) $\mu_m \subset K^{\mathrm{ur}}$ by definition. For a unit u, $\bar u \in \mathbb{F}_{q^f}^\times$ for some f; choose f' with $m(q^f - 1) \mid q^{f'} - 1$ (possible since $p \nmid m(q^f - 1)$); in the cyclic group $\mathbb{F}_{q^{f'}}^\times$ of order $q^{f'} - 1$,

the element $\bar{u}$, of order dividing q^f-1, is an m-th power. The root of $X^m-\bar{u}$ so found is simple (m is a unit), and lifts by (iii). Finally $x=\varpi_K^{am}u$ is then an m-th power, and conversely $v_K(y^m)=mv_K(y)$. □

Convention 7.37 (Frobenius)**.** Frob $=$ Frob$_K$ denotes an *arithmetic Frobenius* of K: any element of G_K whose restriction to K^{ur} is the generator of Proposition 7.36(i), that is, which induces $x\mapsto x^q$ on $\overline{\mathbb{F}}_q$. It is well defined modulo I_K (and, in a global setting, up to conjugation). The *geometric Frobenius* is $\Phi=\mathrm{Frob}^{-1}$. The book's Frob$_p$ is always arithmetic (Appendix B, convention B-C2).

(a) Frob acts on μ_m ($p\nmid m$) by $\zeta\mapsto\zeta^q$, so $\chi_\ell(\mathrm{Frob})=q$ and $\chi_\ell(\Phi)=q^{-1}$ for $\ell\neq p$ (Proposition 7.39).

(b) Since Frob is defined only modulo I_K, a statement about $\rho(\mathrm{Frob})$ for a ramified ρ must be checked to be independent of the lift, as in Corollary 7.52 and Theorem 7.58(iv).

(c) An eigenvalue λ of Frob is an eigenvalue λ^{-1} of Φ. When the multiset of eigenvalues on the relevant space is stable under inversion (as on ad^0V at a good prime, or on a line where Frobenius acts by ±1), the two conventions give the same L-factor; otherwise they do not (the Steinberg case, Proposition 7.88).

(d) Group-theoretic statements (the tame relation, conjugation actions, the matrices in the proof of Lemma lem:tamfactor, Frobenius on Kummer classes) use Frob; local L-factors use Φ (Definition 7.77). The paper fixes the same convention in Section 1.1: Frob$_p$ is an arithmetic Frobenius and Frob$_p^{-1}$ a geometric one; its table, Lemma lem:euler and Lemma lem:fpr use the geometric Frobenius, and the proof of Lemma lem:tamfactor the arithmetic one.

Proposition 7.38 (unramified base change)**.** *Let $K/\mathbb{Q}_p$ be finite unramified of degree f. Then $K^{\mathrm{ur}}=\mathbb{Q}_p^{\mathrm{ur}}$ and $K^{\mathrm{tame}}=\mathbb{Q}_p^{\mathrm{tame}}$, so $I_K=I_p$ and $P_K=P_p$ as subgroups of $G_K\subseteq G_{\mathbb{Q}_p}$, and* $\mathrm{Frob}_K\equiv\mathrm{Frob}_{\mathbb{Q}_p}^f \pmod{I_p}$. *Consequently, for a representation ρ of $G_{\mathbb{Q}_p}$, the image $\rho(I_p)$, the invariants V^{I_p} and the property of being tamely or wildly ramified are unchanged by restriction to G_K; so are the monodromy operator and the Swan and Artin conductors, which are defined later (forward references: Theorem 7.68, Definition 7.81, Definition 7.83). For an arbitrary finite $K/\mathbb{Q}_p$, $K^{\mathrm{ur}}=K\mathbb{Q}_p^{\mathrm{ur}}$ and $I_K=I_p\cap G_K$ has index $e(K/\mathbb{Q}_p)$ in I_p.*

Proof. For an arbitrary finite K: $\mathbb{Q}_p^{\mathrm{ur}}=\mathbb{Q}_p(\mu_m : p\nmid m)\subseteq K^{\mathrm{ur}}$, and $K^{\mathrm{ur}}=K(\mu_m : p\nmid m)\subseteq K\mathbb{Q}_p^{\mathrm{ur}}$; so $K^{\mathrm{ur}}=K\mathbb{Q}_p^{\mathrm{ur}}$ and $I_K=\mathrm{Gal}(\overline{\mathbb{Q}}_p/K\mathbb{Q}_p^{\mathrm{ur}})=G_K\cap I_p$. Its index in I_p is $[K\mathbb{Q}_p^{\mathrm{ur}}:\mathbb{Q}_p^{\mathrm{ur}}]$ (Chapter 5, translation theorem). Let K_0 be the largest unramified subextension, of degree $f(K/\mathbb{Q}_p)$, so that $K=K_0(\pi)$ with π a root of an Eisenstein polynomial of degree $e=e(K/\mathbb{Q}_p)$ over K_0 (Theorem 7.34(iii), Theorem 7.27). That polynomial stays Eisenstein over every finite unramified extension of K_0, hence irreducible over $K_0^{\mathrm{ur}}=\mathbb{Q}_p^{\mathrm{ur}}$; so the index is e. If K is unramified, $K=K_0\subseteq\mathbb{Q}_p^{\mathrm{ur}}$, so $K^{\mathrm{ur}}=\mathbb{Q}_p^{\mathrm{ur}}$. A finite extension of K is tamely ramified over K iff it is over $\mathbb{Q}_p$, e being multiplicative and $e(K/\mathbb{Q}_p)=1$; so $K^{\mathrm{tame}}=\mathbb{Q}_p^{\mathrm{tame}}$ (Theorem 7.45(ii)). Frob$_K$ induces $x\mapsto x^{p^f}$ on the residue field. The image $\rho(I_p)$, the invariants V^{I_p} and tameness ($\rho(P_p)=1$) depend only on the subgroups I_p, P_p, which do not change. The monodromy operator is determined by ρ on an open subgroup of I_p and by the tame character, which is the same for K and $\mathbb{Q}_p$ because p is a uniformiser of both (Theorem 7.47(i)). For the conductors see

Theorem 7.82(iii). (These two forward references do not use the present proposition, so there is no circularity.) □

Proposition 7.39 (the cyclotomic character locally)**.** *(i) For a prime $\ell \neq p$, $\mathbb{Q}_p(\mu_{\ell^k})/\mathbb{Q}_p$ is unramified of degree the order of p in $(\mathbb{Z}/\ell^k)^\times$, and* Frob *acts on μ_{ℓ^∞} by $\zeta \mapsto \zeta^p$. So $\chi_\ell|_{G_{\mathbb{Q}_p}}$ is unramified with $\chi_\ell(\mathrm{Frob}) = p$; more generally $\chi_\ell(\mathrm{Frob}_K) = q$ for K with residue field $\mathbb{F}_q$.*

(ii) For $\ell = p$, $\mathbb{Q}_p(\mu_{p^n})/\mathbb{Q}_p$ is totally ramified with group $(\mathbb{Z}/p^n)^\times$, so $\chi_p(I_p) = \mathbb{Z}_p^\times$, and $\mathbb{Q}_p(\mu_{p^\infty}) \cap \mathbb{Q}_p^{\mathrm{ur}} = \mathbb{Q}_p$.

(iii) Globally, through Proposition 7.32: $\chi_\ell(\mathrm{Frob}_p) = p$ for every prime $p \neq \ell$.

Proof. (i) Write $\mathbb{Q}_{p,f}$ for the unramified extension of degree f. Its residue field is $\mathbb{F}_{p^f}$, so $\mu_{\ell^k} \subset \mathbb{Q}_{p,f}$ iff $\ell^k \mid p^f - 1$ (Corollary 7.19), that is iff f is a multiple of the order f_0 of p in $(\mathbb{Z}/\ell^k)^\times$. The field $\mathbb{Q}_p(\mu_{\ell^k})$ is contained in $\mathbb{Q}_{p,f_0} = \mathbb{Q}_p(\mu_{p^{f_0}-1})$, hence unramified (Theorem 7.34(iii)), so it is some $\mathbb{Q}_{p,f}$ with $f \mid f_0$; it contains μ_{ℓ^k}, so $f_0 \mid f$, and $f = f_0$. By Theorem 7.34(ii) Frob acts on roots of unity of order prime to p by $\zeta \mapsto \zeta^p$; as χ_ℓ is defined by $\sigma(\zeta) = \zeta^{\chi_\ell(\sigma)}$ on μ_{ℓ^∞}, $\chi_\ell(\mathrm{Frob}) = p$, and χ_ℓ is trivial on I_p, which fixes $\mathbb{Q}_p^{\mathrm{ur}} \supset \mu_{\ell^\infty}$. For K with residue field $\mathbb{F}_q$ the same argument gives $\zeta \mapsto \zeta^q$. (ii) Proposition 7.28(i): the image of I_p in $\mathrm{Gal}(\mathbb{Q}_p(\mu_{p^n})/\mathbb{Q}_p)$ is the inertia group, which is everything; so $\chi_p(I_p)$ is dense in $\mathbb{Z}_p^\times$, and closed. An extension that is both unramified and totally ramified is trivial. (iii) follows from (i). □

In the paper 7.40. The proof of Lemma lem:tamagawa-exp passes to the unramified quadratic extension K_2 of $\mathbb{Q}_q$, "which does not change the inertia group": this is Proposition 7.38. It then uses that $\mathbb{Q}_q^{\mathrm{ur}}$ contains μ_{ℓ^t} $(q \neq \ell)$ and that "the units of its valuation ring are ℓ^t-th powers by Hensel's lemma": Proposition 7.36(iv), where Hensel's lemma is applied in a finite, complete, subextension because $\mathbb{Q}_q^{\mathrm{ur}}$ itself is not complete. The conclusion, that q_E is an ℓ^t-th power in $\mathbb{Q}_q^{\mathrm{ur}}$ if and only if $\ell^t \mid n_q$, is the last statement of Proposition 7.36(iv); Theorem 7.58(v) puts it in terms of inertia.

7.5 Ramification groups, inertia and the tame quotient

This section is the heart of the chapter for the paper. It shows that the inertia group I_K has a normal pro-p subgroup P_K with procyclic quotient $\prod_{\ell \neq p} \mathbb{Z}_\ell(1)$, defines the tame character $t_\ell \colon I_K \to \mathbb{Z}_\ell(1)$, and proves the tame relation $\mathrm{Frob}\, t\, \mathrm{Frob}^{-1} = t^q$. The paper uses these facts in Lemma lem:tamfactor (inertia acts through its maximal pro-ℓ quotient, generated by t, and $\mathrm{Frob}^{-1}\, t\, \mathrm{Frob} = t^{q^{-1}}$), in Lemmas lem:IV and lem:euler and Proposition prop:shapes (a finite image of inertia of order prime to q is cyclic, and Frobenius acts on it by the q-th power), in Lemma lem:tamadd (the maximal pro-ℓ quotient of an open subgroup of inertia), and in Remark rem:wild (wild inertia at $q = 2, 3$). Chapter 6 proved the finite-level relation for tamely ramified extensions of number fields modulo one step, that the kernel of $\tau \mapsto \tau(\varpi)/\varpi$ is a p-group; that step is Proposition 7.42(iii).

7.5.1 Ramification groups of a finite Galois extension

Definition 7.41 (lower ramification groups)**.** Let L/K be finite Galois with group G. For an integer $i \geq -1$ put

$$G_i = \{\sigma \in G : \ v_L(\sigma(x) - x) \geq i + 1 \text{ for all } x \in \mathcal{O}_L\}.$$

$G_0 = I(L/K)$ is the *inertia group* and $G_1 = P(L/K)$ the *wild inertia group* of L/K.

The index i measures how close σ is to the identity: $\sigma \in G_i$ means that σ moves every integer of L by something divisible by π^{i+1}. Every σ lies in G_{-1}; $\sigma \in G_0$ means that σ acts trivially on the residue field $\mathcal{O}_L/\mathfrak{m}_L$; and the higher G_i refine this. For $L = \mathbb{Q}_3(\sqrt{-3})$ and the nontrivial σ, the uniformiser $\pi = \sqrt{-3}$ is moved by $\sigma\pi - \pi = -2\sqrt{-3}$, of valuation 1; by Proposition 7.42(i) below this places σ in G_0 but not in G_1. Wild ramification is the case in which some $\sigma \neq 1$ moves everything by at least π^2, and it can happen only when p divides e.

Proposition 7.42. *Let L/K be finite Galois with group G, π a uniformiser of L, L_0 the largest unramified subextension and $e = e(L/K)$.*

(i) $G_{-1} = G$; the G_i are normal in G, decreasing, and $G_i = 1$ for i large. G_0 is the kernel of the surjection $G \to \mathrm{Gal}(k_L/k_K)$, $G_0 = \mathrm{Gal}(L/L_0)$ and $\#G_0 = e$. For $\sigma \in G_0$ and $i \geq 0$: $\sigma \in G_i$ iff $v_L(\sigma(\pi) - \pi) \geq i + 1$. For a subgroup H, $H_i = H \cap G_i$.

(ii) $\theta_0(\sigma) = \sigma(\pi)/\pi \bmod \mathfrak{m}_L$ defines a homomorphism $G_0 \to k_L^\times$, independent of π, with kernel G_1. So G_0/G_1 is cyclic of order prime to p.

(iii) For $i \geq 1$, $\sigma \mapsto \sigma(\pi)/\pi - 1 \bmod \mathfrak{m}_L^{i+1}$ defines a homomorphism $G_i \to \mathfrak{m}_L^i/\mathfrak{m}_L^{i+1} \simeq (k_L, +)$ with kernel G_{i+1}. So G_1 is a p-group, the unique Sylow p-subgroup of G_0, and L/K is tamely ramified iff $G_1 = 1$.

(iv) (Stated.) Put $G_t = G_{\lceil t \rceil}$ for real $t \geq -1$ and $\varphi_{L/K}(u) = \int_0^u dt/[G_0 : G_t]$, with inverse $\psi_{L/K}$; the upper numbering *is $G^v = G_{\psi_{L/K}(v)}$. If H is normal in G then $(G/H)^v = G^v H/H$ (Herbrand), and if G is abelian the jumps of the upper filtration are integers (Hasse-Arf). We do not prove this; see Serre [174, Chapter IV, Section 3, and Chapter V, Section 7].*

Proof. (i) $G_{-1} = G$ trivially. For $\tau \in G$, $v_L(\tau\sigma\tau^{-1}x - x) = v_L(\sigma(\tau^{-1}x) - \tau^{-1}x)$ since τ is an isometry, and τ^{-1} permutes $\mathcal{O}_L$; so G_i is normal. Every element of L is x/ϖ_K^k with $x \in \mathcal{O}_L$, so each $\sigma \neq 1$ moves some $x \in \mathcal{O}_L$, and $G_i = 1$ once $i + 1$ exceeds the finitely many values $v_L(\sigma x - x)$ so obtained. By definition G_0 is the kernel of the action on k_L. An element acts trivially on k_L iff it fixes the Teichmüller lifts $\mu_{q^f-1} \subset L$, $f = f(L/K)$ (reduction is injective on them), iff it fixes $L_0 = K(\mu_{q^f-1})$ (Theorem 7.34); so $G_0 = \mathrm{Gal}(L/L_0)$, of order $[L : L_0] = e$, and $G/G_0 = \mathrm{Gal}(L_0/K) \simeq \mathrm{Gal}(k_L/k_K)$. As L/L_0 is totally ramified, $\mathcal{O}_L = \mathcal{O}_{L_0}[\pi]$ (Theorem 7.27); for $\sigma \in G_0$, which fixes $\mathcal{O}_{L_0}$, $\sigma(\sum c_j\pi^j) - \sum c_j\pi^j = \sum c_j(\sigma(\pi)^j - \pi^j)$ is divisible by $\sigma(\pi) - \pi$, so $\min_x v_L(\sigma x - x) = v_L(\sigma\pi - \pi)$. The last assertion is immediate from the definition. (ii) For $\sigma \in G_0$, $\sigma(\pi)$ is a uniformiser, so $\sigma(\pi)/\pi$ is a unit. If $\pi' = u\pi$, then $\sigma(\pi')/\pi' = (\sigma(\pi)/\pi)(\sigma(u)/u)$ and $\sigma(u) \equiv u \pmod{\mathfrak{m}_L}$, so θ_0 does not depend on π. Then $\sigma\tau(\pi)/\pi = \big(\sigma(\tau\pi)/\tau\pi\big)\big(\tau\pi/\pi\big)$, and the first factor is $\theta_0(\sigma)$ computed with the uniformiser $\tau\pi$; so θ_0 is a homomorphism. Its kernel is $\{v_L(\sigma\pi - \pi) \geq 2\} = G_1$ by (i). As $k_L^\times$ is cyclic of order $\#k_L - 1$, prime to p, so is G_0/G_1. (iii) For $\sigma \in G_i$ $(i \geq 1)$ write $\sigma(\pi) = \pi(1 + a_\sigma)$, $v_L(a_\sigma) \geq i$. First, $\sigma \in G_i$ and $x \in \mathfrak{m}_L^j$ give $v_L(\sigma x - x) \geq i + j$: write $x = \pi^j y$, so $\sigma x - x = \sigma(\pi^j)(\sigma y - y) + y(\sigma(\pi^j) - \pi^j)$, with $v_L(\sigma y - y) \geq i + 1$ and $\sigma(\pi^j) - \pi^j = \pi^j((1 + a_\sigma)^j - 1)$ of valuation $\geq i + j$. Now for $\sigma, \tau \in G_i$, $1 + a_{\sigma\tau} = \frac{\sigma(\tau\pi)}{\tau\pi} \cdot \frac{\tau\pi}{\pi}$ and $\tau\pi = \pi u$ with $u = 1 + a_\tau$; then $\sigma(\tau\pi)/\tau\pi = (1 + a_\sigma)\sigma(u)/u$ and $v_L(\sigma(u) - u) = v_L(\sigma a_\tau - a_\tau) \geq 2i \geq i + 1$. Hence $1 + a_{\sigma\tau} \equiv (1 + a_\sigma)(1 + a_\tau)$ and $a_{\sigma\tau} \equiv a_\sigma + a_\tau \pmod{\mathfrak{m}_L^{i+1}}$. The kernel is $\{v_L(a_\sigma) \geq i + 1\} = G_{i+1}$ by (i). The quotient $\mathfrak{m}_L^i/\mathfrak{m}_L^{i+1}$ is a one-dimensional k_L-vector space, of exponent p; so each G_i/G_{i+1} $(i \geq 1)$ is an elementary abelian p-group, and G_1 is a p-group. It is normal in G_0 with quotient of order prime to p by (ii), so it

is the unique Sylow p-subgroup. If $p \nmid e = \#G_0$ then $G_1 = 1$; conversely, if $G_1 = 1$ then $\#G_0$ divides $\#k_L^\times$, prime to p. □

Example 7.43 (ramification groups of quadratic extensions)**.** Let L/K be a ramified quadratic extension with $\mathcal{O}_L = \mathcal{O}_K[\pi]$, $G = \{1, \sigma\}$. By Proposition 7.42(i), $\sigma \in G_i$ iff $v_L(\sigma\pi - \pi) \geq i + 1$. In (a) to (c), $K = \mathbb{Q}_2$ and $e = 2$, so $v_L = 2v_2$ on $\mathbb{Q}_2$; in particular $v_L(2) = 2$, and $v_L(\sqrt{d}) = \frac{1}{2}v_L(d) = v_2(d)$: $\sqrt{d}$ is a unit if d is odd and a uniformiser if $v_2(d) = 1$.

(a) $\mathbb{Q}_2(i)$: $\pi = 1 + i$ (a root of the Eisenstein polynomial $(X-1)^2 + 1 = X^2 - 2X + 2$), $\sigma\pi - \pi = (1 - i) - (1 + i) = -2i$ has $v_L = v_L(2) = 2$, i being a unit; so $G_0 = G_1 = G$, $G_2 = 1$.

(b) $\mathbb{Q}_2(\sqrt{3}) = \mathbb{Q}_2(\sqrt{-5})$ (since $-5/3 = -15/9$ and $-15 \equiv 1 \pmod 8$ is a square in $\mathbb{Q}_2$, Example 7.16(d)): $\pi = 1 + \sqrt{3}$ (root of $(X-1)^2 - 3 = X^2 - 2X - 2$), $\sigma\pi - \pi = -2\sqrt{3}$ has $v_L = 2$; again $G_1 = G$, $G_2 = 1$.

(c) $\mathbb{Q}_2(\sqrt{d})$ for $d \in \{\pm 2, \pm 10\}$: $\pi = \sqrt{d}$ (root of the Eisenstein polynomial $X^2 - d$, as $v_2(d) = 1$), $\sigma\pi - \pi = -2\sqrt{d}$ has $v_L = 2 + 1 = 3$; so $G_0 = G_1 = G_2 = G$, $G_3 = 1$.

(d) $\mathbb{Q}_p(\sqrt{p^*})$, p odd, and $\mathbb{Q}_3(\sqrt{-3})$: $e = 2$ is prime to p, so $G_1 = 1$. Likewise $\mathbb{Q}_p(\zeta_p)/\mathbb{Q}_p$ ($e = p - 1$) is tame.

These are the wildly ramified quadratic extensions of $\mathbb{Q}_2$ (Proposition 7.60(iii)); their conductor exponents are computed in Theorem 7.82(iv).

Remark 7.44 (the tame relation of Chapter 6). Let L/F be a finite Galois extension of number fields and $\mathfrak{P} \mid \mathfrak{p}$. By Proposition 7.32(i), $I_\mathfrak{P}$ is the inertia group G_0 of $L_\mathfrak{P}/F_\mathfrak{p}$, and the map $\tau \mapsto \tau(\varpi)/\varpi \bmod \mathfrak{P}$ used in Chapter 6 is θ_0 (a uniformiser of the localisation $\mathcal{O}_{L,\mathfrak{P}}$ is one of the completion). By Proposition 7.42(ii), (iii), its kernel is G_1, a p-group. This is the step that Chapter 6 left unproved; so the tame relation $F\tau F^{-1} = \tau^{N\mathfrak{p}}$ for tamely ramified primes is now proved in full.

7.5.2 The inertia group of G_K and the tame quotient

Theorem 7.45 (the filtration $G_K \supset I_K \supset P_K$)**.** *(i) I_K is a closed normal subgroup of G_K with $G_K/I_K \simeq \mathrm{Gal}(\overline{\mathbb{F}}_q/\mathbb{F}_q) \simeq \hat{\mathbb{Z}}$; for every finite Galois L/K, the image of I_K in $\mathrm{Gal}(L/K)$ is $G_0 = I(L/K)$.*

(ii) Let ϖ be a uniformiser of K and fix a compatible system of roots $\varpi^{1/m} \in \overline{\mathbb{Q}}_p$ ($p \nmid m$). A finite extension L/K is tamely ramified iff $L \subseteq K^{\mathrm{ur}}(\varpi^{1/m})$ for some m prime to p. Hence the union K^{tame} of all finite tamely ramified extensions of K in $\overline{\mathbb{Q}}_p$ is the field $\bigcup_{p\nmid m} K^{\mathrm{ur}}(\varpi^{1/m})$, Galois over K.

(iii) $P_K = \mathrm{Gal}(\overline{\mathbb{Q}}_p/K^{\mathrm{tame}})$ is a closed normal subgroup of G_K contained in I_K; its image in $\mathrm{Gal}(L/K)$ is $G_1(L/K)$ for every finite Galois L/K; it is a pro-p group, and every pro-p subgroup of I_K is contained in it (it is the unique pro-p Sylow subgroup of I_K).

(iv) (Stated.) The upper numbering of Proposition 7.42(iv) is compatible with quotients, so it defines a decreasing filtration $(G_K^u)_{u \geq -1}$ by closed normal subgroups, with $G_K^{-1} = G_K$, $G_K^0 = I_K$ and P_K the closure of $\bigcup_{u>0} G_K^u$. We do not prove this; see Serre [174, Chapter IV, Section 3].

Proof. (i) I_K is the kernel of the continuous restriction map $G_K \to \mathrm{Gal}(K^{\mathrm{ur}}/K) \simeq \hat{\mathbb{Z}}$ (Proposition 7.36(i)). Its image in $\mathrm{Gal}(L/K)$ is $\mathrm{Gal}(L/L \cap K^{\mathrm{ur}})$ (Chapter 5); $L \cap K^{\mathrm{ur}}$ is unramified and contains every unramified subextension, so it is L_0, and $\mathrm{Gal}(L/L_0) = G_0$ by Proposition 7.42(i). (ii) Suppose $p \nmid e(L/K)$. L/L_0 is totally and tamely ramified of degree $e = e(L/K)$, so $L = L_0(\alpha)$ with $\alpha^e = \varpi_0$ a uniformiser of L_0 (Proposition 7.33). Write $\varpi_0 = \varpi u$ with $u \in \mathcal{O}_{L_0}^\times \subseteq \mathcal{O}_{K^{\mathrm{ur}}}^\times$; then $u = \beta^e$ with $\beta \in K^{\mathrm{ur}}$ (Proposition 7.36(iv)), so $(\alpha/\beta)^e = \varpi$ and $\alpha/\beta = \zeta\varpi^{1/e}$ with $\zeta \in \mu_e \subset K^{\mathrm{ur}}$. Hence $L \subseteq K^{\mathrm{ur}}(\varpi^{1/e})$. Conversely, if $L \subseteq K^{\mathrm{ur}}(\varpi^{1/m})$ then $L \subseteq M = K_f(\varpi^{1/m})$ for some f; $X^m - \varpi$ is Eisenstein over K_f, so $e(M/K) = m$ is prime to p, and $e(L/K) \mid e(M/K)$. The fields $K^{\mathrm{ur}}(\varpi^{1/m})$ form a directed family ($K^{\mathrm{ur}}(\varpi^{1/m})$ and $K^{\mathrm{ur}}(\varpi^{1/m'})$ lie in $K^{\mathrm{ur}}(\varpi^{1/mm'})$), so their union is a field, equal to K^{tame}; it is normal over K because the conjugates of $\varpi^{1/m}$ are the $\zeta\varpi^{1/m}$, $\zeta \in \mu_m \subset K^{\mathrm{ur}}$. (iii) P_K is closed and normal since K^{tame}/K is Galois, and $P_K \subseteq I_K$ since $K^{\mathrm{ur}} \subseteq K^{\mathrm{tame}}$. Its image in $\mathrm{Gal}(L/K)$ is $\mathrm{Gal}(L/L_t)$ with $L_t = L \cap K^{\mathrm{tame}}$, the largest tamely ramified subextension. Let $L_1 = L^{G_1}$. The inertia group of L_1/K is the image G_0/G_1 of G_0 (by (i), applied to L and to L_1), of order prime to p; so $e(L_1/K)$ is prime to p and $L_1 \subseteq L_t$. Conversely the image of the p-group G_1 in $\mathrm{Gal}(L_t/K)$ lies in the inertia group of L_t/K, of order $e(L_t/K)$ prime to p; so it is trivial, and $L_t \subseteq L_1$. Hence the image of P_K is G_1, a p-group, and $P_K = \varprojlim_L G_1(L/K)$ is pro-p. If $Q \subseteq I_K$ is pro-p, its image in each $\mathrm{Gal}(L/K)$ is a p-subgroup of G_0, hence lies in the unique Sylow p-subgroup G_1, the image of P_K; as P_K is closed, $Q \subseteq P_K$. □

Corollary 7.46 (G_K is a semidirect product)**.** *Let* $\mathrm{Frob} \in G_K$ *be an arithmetic Frobenius lift and* Z *the closed subgroup it generates. Then* $Z \simeq \hat{\mathbb{Z}}$, $Z \cap I_K = 1$ *and* $G_K = I_K \rtimes Z$. *Consequently a continuous character* ψ *of* I_K *with* $\psi(\mathrm{Frob}\,\sigma\,\mathrm{Frob}^{-1}) = \psi(\sigma)$ *for all* $\sigma \in I_K$ *extends to a continuous character* χ *of* G_K, *by* $\chi(\sigma z) = \psi(\sigma)$ *(*$\sigma \in I_K$, $z \in Z$*).*

Proof. Z is procyclic, so $n \mapsto \mathrm{Frob}^n$ extends to a continuous surjection $\hat{\mathbb{Z}} \to Z$ (each finite quotient of Z is cyclic, generated by the image of Frob). The composite $\hat{\mathbb{Z}} \to Z \to G_K/I_K \simeq \hat{\mathbb{Z}}$ sends 1 to 1, hence is the identity; so $\hat{\mathbb{Z}} \to Z$ is injective, $Z \simeq \hat{\mathbb{Z}}$, $Z \cap I_K = 1$, and Z maps onto G_K/I_K, so $G_K = I_K Z$. The map $I_K \times Z \to G_K$ is a continuous bijection of compact spaces, hence a homeomorphism. For the extension, $(\sigma z)(\sigma' z') = \sigma(z\sigma' z^{-1})zz'$ and $\psi(z\sigma' z^{-1}) = \psi(\sigma')$ (z is a limit of powers of Frob and ψ is continuous), so χ is a homomorphism, continuous by the homeomorphism. □

Theorem 7.47 (the tame character)**.** *Let* m *be prime to* p *and* ϖ *a uniformiser of* K.

(i) $\theta_m \colon I_K \to \mu_m$, $\sigma \mapsto \sigma(\varpi^{1/m})/\varpi^{1/m}$, *is a continuous surjective homomorphism. It does not depend on the root* $\varpi^{1/m}$ *or on the uniformiser* ϖ, *and it does not change when* K *is replaced by a finite unramified extension.*

(ii) For compatible roots, $\theta_{mm'}^{m'} = \theta_m$. *The limit* $\theta \colon I_K \to \varprojlim_{p\nmid m} \mu_m = \prod_{\ell \neq p} \mathbb{Z}_\ell(1)$ *is surjective with kernel* P_K*:*

$$I_K/P_K \;\simeq\; \prod_{\ell \neq p} \mathbb{Z}_\ell(1).$$

This group is abelian and procyclic, and each of its finite quotients has order prime to p.

(iii) For a prime $\ell \neq p$, *the* tame character $t_\ell \colon I_K \to \mathbb{Z}_\ell(1)$, $\sigma \mapsto \left(\sigma(\varpi^{1/\ell^k})/\varpi^{1/\ell^k}\right)_k$, *is the* ℓ*-component of* θ. *It is surjective, every finite quotient of its kernel has order prime to* ℓ, *and* t_ℓ *identifies the maximal pro-*ℓ *quotient* $I_K^{(\ell)}$ *of* I_K *with* $\mathbb{Z}_\ell(1)$. *A topological generator* t *of* $I_K^{(\ell)}$ *(or of* I_K/P_K*) is called a* generator of tame inertia.

(iv) *Every continuous homomorphism from I_K to a pro-ℓ group (for instance to $1+\ell\,\mathrm{M}_n(\mathbb{Z}_\ell)$, or to a group of unipotent matrices over $\mathbb{Z}_\ell$) factors through t_ℓ.*

(v) *If L/K is finite with ramification index e, then $I_L \subseteq I_K$ and $\theta_{m,K}|_{I_L} = \theta_{m,L}^{e}$; so $t_{\ell,K}|_{I_L} = e\,t_{\ell,L}$, and the two have the same kernel.*

Proof. (i) $\mu_m \subset K^{\mathrm{ur}}$ is fixed by I_K. So for another root $\zeta\varpi^{1/m}$ the quotient is unchanged, and $\theta_m(\sigma\tau) = \sigma(\theta_m(\tau)\varpi^{1/m})/\varpi^{1/m} = \theta_m(\tau)\theta_m(\sigma)$. If $\varpi' = u\varpi$ with $u \in \mathcal{O}_K^\times$, then $u^{1/m}$ can be chosen in K^{ur} (Proposition 7.36(iv)), where it is fixed by I_K, and $(\varpi')^{1/m} = \zeta u^{1/m}\varpi^{1/m}$ gives the same character. A finite unramified extension K' has $I_{K'} = I_K$ and ϖ as a uniformiser (Proposition 7.38). θ_m factors through $\mathrm{Gal}(K^{\mathrm{ur}}(\varpi^{1/m})/K^{\mathrm{ur}})$, so it is continuous. Since $X^m - \varpi$ is Eisenstein over every K_f, it is irreducible over K^{ur}, so that Galois group has order m, and it maps injectively to μ_m by θ_m; as I_K maps onto it, θ_m is surjective. (ii) $(\varpi^{1/mm'})^{m'} = \varpi^{1/m}$ gives the compatibility. The kernel of θ is the subgroup fixing every $\varpi^{1/m}$, that is $\mathrm{Gal}(\overline{\mathbb{Q}}_p/K^{\mathrm{tame}}) = P_K$ by Theorem 7.45(ii). The image is closed (compact) and surjects onto every μ_m, so it is everything. By the Chinese remainder theorem $\mu_m = \prod_\ell \mu_{\ell^{v_\ell(m)}}$, so the limit is $\prod_{\ell\neq p}\mathbb{Z}_\ell(1) \simeq \prod_{\ell\neq p}\mathbb{Z}_\ell$, which is procyclic. An open subgroup contains the kernel of some projection to μ_m, so finite quotients are quotients of some μ_m, of order prime to p. (iii) Surjectivity is (ii). The kernel of t_ℓ is an extension of $\prod_{\ell'\neq\ell,p}\mathbb{Z}_{\ell'}(1)$ by P_K; a finite quotient of it is an extension of a quotient of the former (order prime to ℓ) by a quotient of P_K (a p-group), so it has order prime to ℓ. If $f\colon I_K \to H$ is a continuous homomorphism to a pro-ℓ group, the image of $\ker t_\ell$ in each finite quotient of H is an ℓ-group of order prime to ℓ, hence trivial; so f kills $\ker t_\ell$ and factors through $I_K/\ker t_\ell \simeq \mathbb{Z}_\ell(1)$, which is itself pro-$\ell$. This proves (iii) and (iv); $1+\ell\,\mathrm{M}_n(\mathbb{Z}_\ell)$ is pro-ℓ because its quotients by $1+\ell^k\,\mathrm{M}_n(\mathbb{Z}_\ell)$ have order a power of ℓ (Chapter 1). (v) $L^{\mathrm{ur}} = LK^{\mathrm{ur}} \supseteq K^{\mathrm{ur}}$ (as in Proposition 7.38), so $I_L \subseteq I_K$. Write $\varpi_K = \varpi_L^e u$ with $u \in \mathcal{O}_L^\times$ and choose $u^{1/m} \in L^{\mathrm{ur}}$; then $\varpi_K^{1/m} = \zeta(\varpi_L^{1/m})^e u^{1/m}$ for some $\zeta \in \mu_m$, and $\sigma \in I_L$ fixes ζ and $u^{1/m}$. Since $\mathbb{Z}_\ell(1)$ is torsion free, $e\,t_{\ell,L}$ and $t_{\ell,L}$ have the same kernel. □

Corollary 7.48 (open subgroups of inertia)**.** *Every open subgroup U of I_K is I_L for some finite extension L/K. Its maximal pro-ℓ quotient ($\ell \neq p$) is $\mathbb{Z}_\ell(1)$, through $t_{\ell,L}$; equivalently, every continuous homomorphism from U to a pro-ℓ group factors through $t_{\ell,K}|_U$.*

Proof. The fixed field F of U is a finite extension of K^{ur} (Chapter 5), generated by finitely many elements, each algebraic over K; let L be the extension of K they generate. Then $L^{\mathrm{ur}} = LK^{\mathrm{ur}} = F$ (Theorem 7.47(v)), so $I_L = \mathrm{Gal}(\overline{\mathbb{Q}}_p/F) = U$. Now apply Theorem 7.47(iii), (iv) to L and (v). □

Corollary 7.49 (a Frobenius fixing the roots of a uniformiser)**.** *Let ϖ be a uniformiser of K, $(\varpi^{1/m})_{p\nmid m}$ a compatible system of roots and $K_\varpi = K(\varpi^{1/m} : p \nmid m)$. There is an arithmetic Frobenius lift* $\mathrm{Frob} \in G_K$ *fixing K_ϖ; two such lifts differ by an element of P_K.*

Proof. Each $K(\varpi^{1/m})$ is totally ramified over K (Eisenstein), so $K_\varpi \cap K^{\mathrm{ur}} = K$. By the translation theorem (Chapter 5), restriction $G_{K_\varpi} \to \mathrm{Gal}(K^{\mathrm{ur}}/K)$ is surjective, and any preimage of the Frobenius generator is the required lift. Two lifts differ by an element of $G_{K_\varpi} \cap I_K$, which fixes every $\varpi^{1/m}$, so has $\theta = 1$ and lies in P_K. □

Theorem 7.50 (the tame relation)**.** *(i) For $\tau \in G_K$ and $\sigma \in I_K$: $\theta_m(\tau\sigma\tau^{-1}) = \tau(\theta_m(\sigma))$, and $t_\ell(\tau\sigma\tau^{-1}) = \chi_\ell(\tau)\,t_\ell(\sigma)$ (in the additive notation for $\mathbb{Z}_\ell(1)$).*

(ii) For every arithmetic Frobenius lift $\mathrm{Frob} \in G_K$ *and every* $t \in I_K/P_K$,

$$\mathrm{Frob}\; t\; \mathrm{Frob}^{-1} = t^{q}, \qquad \textit{equivalently} \qquad \mathrm{Frob}^{-1}\; t\; \mathrm{Frob} = t^{q^{-1}},$$

where q^{-1} *is the inverse of* q *in the ring* $\prod_{\ell \neq p} \mathbb{Z}_\ell$ *of exponents of the procyclic group* I_K/P_K. *For the geometric Frobenius,* $\Phi\, t\, \Phi^{-1} = t^{q^{-1}}$. *The same relations hold in* $I_K^{(\ell)} \simeq \mathbb{Z}_\ell(1)$, *with* $q^{-1} \in \mathbb{Z}_\ell$.

(iii) Let $\mathrm{Frob} \in G_K$ *be any arithmetic Frobenius lift. Then* $\mathrm{Gal}(K^{\mathrm{tame}}/K) = (I_K/P_K) \rtimes \overline{\langle \mathrm{Frob} \rangle} \simeq \left(\prod_{\ell \neq p} \mathbb{Z}_\ell(1)\right) \rtimes \hat{\mathbb{Z}}$, *the generator* $1 \in \hat{\mathbb{Z}}$ *acting by multiplication by* q. *(Stated.) As a profinite group it is generated by* t *and* Frob *subject to the single relation* $\mathrm{Frob}\; t\; \mathrm{Frob}^{-1} = t^{q}$; *see [143, Chapter VII, Section 5].*

Proof. (i) Put $\alpha = \varpi^{1/m}$. Since $\tau(\alpha)$ is a root of $X^m - \varpi$, $\tau(\alpha) = \zeta_\tau^{-1}\alpha$ for some $\zeta_\tau \in \mu_m$, i.e. $\tau^{-1}(\alpha) = \tau^{-1}(\zeta_\tau)\alpha$. As σ fixes $\mu_m \subset K^{\mathrm{ur}}$,

$$\tau\sigma\tau^{-1}(\alpha) = \tau\sigma\big(\tau^{-1}(\zeta_\tau)\alpha\big) = \tau\big(\tau^{-1}(\zeta_\tau)\theta_m(\sigma)\alpha\big) = \zeta_\tau\, \tau(\theta_m(\sigma))\, \zeta_\tau^{-1}\alpha = \tau(\theta_m(\sigma))\, \alpha.$$

Passing to the limit over $m = \ell^k$ gives the formula for t_ℓ, since τ acts on $\mathbb{Z}_\ell(1)$ through χ_ℓ. (ii) Frob acts on μ_m by $\zeta \mapsto \zeta^q$ (Convention 7.37(a)), so $\theta(\mathrm{Frob}\; \sigma\; \mathrm{Frob}^{-1}) = \theta(\sigma)^q$; and Frob^{-1} acts by the inverse map $\zeta \mapsto \zeta^{q'}$, $qq' \equiv 1 \pmod m$, so $\theta(\mathrm{Frob}^{-1}\, \sigma\, \mathrm{Frob}) = \theta(\sigma)^{q^{-1}}$. As θ identifies I_K/P_K with $\prod \mathbb{Z}_\ell(1)$, these are the stated relations; $\Phi = \mathrm{Frob}^{-1}$ gives the last one, and projecting to the ℓ-component gives the relations in $I_K^{(\ell)}$. (iii) The proof of Corollary 7.46 applies verbatim to the profinite group $\mathrm{Gal}(K^{\mathrm{tame}}/K) = G_K/P_K$, its closed normal subgroup $\mathrm{Gal}(K^{\mathrm{tame}}/K^{\mathrm{ur}}) = I_K/P_K$ (with quotient $G_K/I_K \simeq \hat{\mathbb{Z}}$) and the image of Frob: the closure of $\langle \mathrm{Frob} \rangle$ in G_K/P_K is isomorphic to $\hat{\mathbb{Z}}$, meets I_K/P_K trivially, and $\mathrm{Gal}(K^{\mathrm{tame}}/K)$ is the semidirect product of I_K/P_K by it; the action is (ii). □

Warning 7.51 (the sign in the tame relation). With the arithmetic Frobenius, conjugation by Frob raises tame inertia to the power q; with the geometric one, $\Phi\, t\, \Phi^{-1} = t^{q^{-1}}$. The paper writes "$\mathrm{Frob}^{-1}\, t\, \mathrm{Frob} = t^{q^{-1}}$" in the proof of Lemma lem:tamfactor, with Frob arithmetic: this is the second form in Theorem 7.50(ii), and it is correct. Every q prime to $m \in \{3, 4, 6\}$ satisfies $q \equiv \pm 1 \pmod m$, hence $q^{-1} \equiv q \pmod m$; so the distinction is invisible on inertia images of order 3, 4 or 6 (Corollary 7.52), but not on $\mathbb{Z}_\ell(1)$, where it decides whether Frob acts on $H^1(I_q, \cdot)$ through q or through q^{-1}.

Corollary 7.52 (finite tame images of inertia)**.** *Let* $\rho\colon G_K \to H$ *be a continuous homomorphism to a Hausdorff topological group with* $\rho(I_K)$ *finite of order prime to* p *(for example* $\rho\colon G_K \to \mathrm{GL}_n(\mathbb{Q}_\ell)$ *continuous with such an image of inertia). Then* $\rho(P_K) = 1$; $\rho|_{I_K}$ *factors through* I_K/P_K, *so* $\rho(I_K)$ *is cyclic, generated by* $\rho(t)$ *for any generator* t *of* I_K/P_K; *and for every arithmetic Frobenius lift and every* $h \in \rho(I_K)$,

$$\rho(\mathrm{Frob})\, h\, \rho(\mathrm{Frob})^{-1} = h^{q}.$$

If $\rho(I_K) = \langle g \rangle$ *has order* m, *then* $\rho(\mathrm{Frob})$ *commutes with* g *iff* $q \equiv 1 \pmod m$, *and it conjugates* g *to* g^{-1} *iff* $q \equiv -1 \pmod m$.

Proof. The kernel of $\rho|_{I_K}$ is closed of finite index, hence open, so $N = \ker \rho|_{I_K}$ is an open normal subgroup of I_K. The image of P_K in the finite group I_K/N is a quotient of P_K by an

open subgroup, a p-group (Theorem 7.45(iii)); its order divides $\#\rho(I_K)$, which is prime to p; so $\rho(P_K) = 1$. Then $\rho(I_K)$ is a quotient of the procyclic I_K/P_K, and the image of the dense subgroup $\langle t\rangle$ is a dense subgroup of a finite discrete group, hence everything. For $h = \rho(\sigma)$, $\rho(\mathrm{Frob})h\rho(\mathrm{Frob})^{-1} = \rho(\mathrm{Frob}\ \sigma\ \mathrm{Frob}^{-1}) = \rho(\sigma^q) = h^q$ by Theorem 7.50(ii) (the relation holds modulo P_K, which ρ kills). Another lift is $\mathrm{Frob}\,\sigma'$ with $\sigma' \in I_K$, and $\rho(\sigma')$ commutes with h, $\rho(I_K)$ being abelian. Finally $g^q = g$ iff $m \mid q-1$, and $g^q = g^{-1}$ iff $m \mid q+1$. □

Proposition 7.53 (the image of wild inertia)**.** *Let $\ell \neq p$, E_λ a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}$ and uniformiser ϖ_λ, and $\rho\colon G_K \to \mathrm{GL}_n(\mathcal{O})$ continuous. Then $\rho(P_K)$ is a finite p-group, mapping injectively to $\mathrm{GL}_n(\mathcal{O}/\varpi_\lambda)$. Moreover:*

(i) $I_1 = I_K \cap \rho^{-1}(1 + \ell^2\,\mathrm{M}_n(\mathcal{O}))$ is an open subgroup of I_K, normal in G_K, and $\rho|_{I_1}$ factors through $t_\ell|_{I_1}$;

(ii) ρ is tamely ramified (that is, $\rho(P_K) = 1$) iff $\rho(I_K)$ contains no element of order p; in particular if $\rho(I_K)$ is finite of order prime to p.

Proof. $\Gamma_1 = 1 + \varpi_\lambda\,\mathrm{M}_n(\mathcal{O})$ is an open normal pro-ℓ subgroup of $\mathrm{GL}_n(\mathcal{O})$: its quotients by $1 + \varpi_\lambda^k\,\mathrm{M}_n(\mathcal{O})$ are successive extensions of copies of the additive group $\mathrm{M}_n(\mathcal{O}/\varpi_\lambda)$. The group $P' = P_K \cap \rho^{-1}(\Gamma_1)$ is open in P_K, hence pro-p, and $\rho(P')$ is a compact subgroup of Γ_1, so pro-ℓ, and a continuous image of a pro-p group, so pro-p (its finite quotients are quotients of finite quotients of P'). Hence $\rho(P') = 1$, $\rho(P_K) \cap \Gamma_1 = 1$, and $\rho(P_K)$ embeds in $\mathrm{GL}_n(\mathcal{O}/\varpi_\lambda)$; being a finite continuous image of a pro-p group, it is a p-group. (i) $1 + \ell^2\,\mathrm{M}_n(\mathcal{O})$ is open, normal and pro-ℓ, so I_1 is open in I_K and normal in G_K, and $I_1 = I_L$ for a finite L/K (Corollary 7.48); $\rho|_{I_1}$ is a homomorphism to a pro-ℓ group, so it factors through $t_{\ell,K}|_{I_1}$ by Corollary 7.48. (ii) If $\rho(P_K) \neq 1$ it is a nontrivial p-group, which contains an element of order p. Conversely, if $\rho(P_K) = 1$ then $\rho(I_K)$ is a continuous image of I_K/P_K, a profinite abelian group all of whose finite quotients have order prime to p; so is $\rho(I_K)$, and an element of order p would generate a finite subgroup of order p, whose image in a suitable finite quotient of $\rho(I_K)$ is nontrivial. □

Remark 7.54. Nothing in Proposition 7.53 forbids wild ramification for a general ρ at $p \geq 5$: $\mathrm{GL}_2(\mathbb{Z}_\ell)$ contains elements of order 5 when $\ell \equiv 1 \pmod 5$. For $\rho = \rho_{E,\ell}$ with potentially good reduction, the characteristic polynomials of the elements of $\rho(I_K)$ have integer coefficients independent of ℓ, so their orders lie in $\{1,2,3,4,6\}$, and the image is tame for $p \geq 5$ (Serre and Tate [179, Section 2]; Chapter 10). At $p = 2, 3$ the image can be wild: Q_8 or $\mathrm{SL}_2(\mathbb{F}_3)$ at $p = 2$, cyclic of order 3 or 6 at $p = 3$; an image of order 3 is wild at $p = 3$, because I_K/P_K has no quotient of order 3, and tame at $p = 2$. These are the facts behind Remark rem:wild.

Example 7.55 (the tame relation at a finite level)**.** Let $\ell \neq q$ be primes, $m = \ell^k$, and $L = \mathbb{Q}_q(\mu_m, q^{1/m})$. Fix a primitive $\zeta \in \mu_m$. An element $\sigma \in \mathrm{Gal}(L/\mathbb{Q}_q)$ is determined by (a,b) with $\sigma(\zeta) = \zeta^a$, $\sigma(q^{1/m}) = \zeta^b q^{1/m}$, and $\sigma_{a,b}\sigma_{a',b'} = \sigma_{aa',ab'+b}$, because $\sigma_{a,b}(\zeta^{b'}q^{1/m}) = \zeta^{ab'}\zeta^b q^{1/m}$: the group is a subgroup of the affine group of $\mathbb{Z}/m$ (Chapter 5). Since $\mathbb{Q}_q(\mu_m)$ is unramified with group generated by $\zeta \mapsto \zeta^q$, the values of a are exactly the powers of q; and $X^m - q$ is Eisenstein over $\mathbb{Q}_q(\mu_m)$, hence irreducible, so each automorphism of $\mathbb{Q}_q(\mu_m)$ has m extensions to L, one for each value of b. So the group is $\{(a,b) : a \in \langle q\rangle \subseteq (\mathbb{Z}/m)^\times,\ b \in \mathbb{Z}/m\}$, of order $m \cdot \#\langle q\rangle$. The inertia group fixes the unramified field $\mathbb{Q}_q(\mu_m)$, so it is contained in $\{a = 1\}$, and it has order $e = m$ (Proposition 7.42(i)); so it is $\{a = 1\}$, generated by $t = \sigma_{1,1}$, and $t_\ell \bmod m$ is $\sigma_{1,b} \mapsto \zeta^b$ (as $\sigma_{1,b}^n = \sigma_{1,nb}$). The element $\mathrm{Frob} = \sigma_{q,0}$ is a Frobenius fixing $q^{1/m}$. Then

$$\mathrm{Frob}\ t\ \mathrm{Frob}^{-1} = \sigma_{q,q}\sigma_{q',0} = \sigma_{1,q} = t^q, \qquad \mathrm{Frob}^{-1}\ t\ \mathrm{Frob} = \sigma_{q',q'}\sigma_{q,0} = \sigma_{1,q'} = t^{q'},$$

where $qq' \equiv 1 \pmod m$; here $\mathrm{Frob}^{-1} = \sigma_{q',0}$, since $\sigma_{q,0}\sigma_{q',0} = \sigma_{1,0}$, and the first product is $\mathrm{Frob}\, t = \sigma_{q,0}\sigma_{1,1} = \sigma_{q,q}$ followed by $\sigma_{q,q}\sigma_{q',0} = \sigma_{qq',q\cdot 0+q} = \sigma_{1,q}$. For $(q,\ell,k) = (7,3,2)$ these are t^7 and t^4; for $(13,3,2)$, t^4 and t^7; for $(2,3,2)$, t^2 and t^5 (all checked by composing the pairs).

In the paper 7.56. In the proof of Lemma lem:tamfactor: "The inertia group $I = I_q$ acts through its maximal pro-ℓ tame quotient, generated by an element t" is Theorem 7.47(iii), (iv), since I_q acts on $T_\ell E$ through unipotent matrices over $\mathbb{Z}_\ell$ (a pro-ℓ group); "the kernel of $I \to \langle t\rangle$ has trivial pro-ℓ quotient" is the statement that every finite quotient of $\ker t_\ell$ has order prime to ℓ; and "$\mathrm{Frob}^{-1}\, t\, \mathrm{Frob} = t^{q^{-1}}$" is Theorem 7.50(ii) for the arithmetic Frobenius. In the proof of Lemma lem:IV, "The order 3 is prime to q, so the image is a quotient of the tame inertia group", and in the proof of Lemma lem:euler, "Frobenius centralises σ if $q \equiv 1 \pmod 3$ and inverts it if $q \equiv 2$", are Corollary 7.52, which needs only $q \nmid \#\rho(I_q)$, not $q \geq 5$. In Proposition prop:shapes(ii), the extension of the $G_{\mathbb{Q}_q}$-invariant quadratic character ψ of I_q to $G_{\mathbb{Q}_q} = I_q \rtimes \langle\phi\rangle$ is Corollary 7.46. In Lemma lem:tamadd, the fact that the maximal pro-ℓ abelian quotient of the open subgroup $K \subseteq I_q$ is $\mathbb{Z}_\ell(1)$ is Corollary 7.48.

7.6 Kummer theory over local fields; quadratic characters

The Tate curve makes the Kummer extension of a single element $q_E \in \mathbb{Q}_q^\times$ appear inside $T_\ell E$, and the paper reads off the action of inertia and Frobenius on $T_\ell E$ from the Kummer cocycle of q_E. This section computes that cocycle on inertia ($v_K(x)$ times the tame character) and on Frobenius (the class of the reduction of the unit part), with all the choices made explicit. It then describes the quadratic characters of $G_{\mathbb{Q}_p}$ and the local behaviour of the global characters χ_d, and states local class field theory in the form needed for conductors. The paper uses this in Lemmas lem:tamagawa-exp and lem:tamfactor (Kummer classes), in Lemma lem:twist and Theorem thm:twist (the twist by χ_{q^*} is unramified outside q and tame at odd q), in Lemma lem:euler and Proposition prop:shapes ($V = V' \otimes \chi$ locally) and in Theorem thm:qual. The cohomological statements (Hilbert 90, $H^1(K,\mathbb{Z}_\ell(1)) = \widehat{K^\times}$) are proved in Chapter 17; here we prove the field-theoretic half.

Proposition 7.57 (Kummer theory over K)**.** *Let $\ell \neq p$ and $x \in K^\times$.*

(i) (Chapter 5, recalled.) For a compatible system of roots $(x^{1/\ell^k})_k$ in $\overline{\mathbb{Q}}_p$, the Kummer cocycle *$\kappa_x(\sigma) = \left(\sigma(x^{1/\ell^k})/x^{1/\ell^k}\right)_k \in \mathbb{Z}_\ell(1)$ is continuous and satisfies $\kappa_x(\sigma\tau) = \kappa_x(\sigma) + \chi_\ell(\sigma)\kappa_x(\tau)$. Changing the system changes κ_x by the coboundary $\sigma \mapsto (\chi_\ell(\sigma) - 1)z$, $z \in \mathbb{Z}_\ell(1)$; $\kappa_{xy} = \kappa_x + \kappa_y$ for the product systems; and for any extension $K' \supseteq K(\mu_{\ell^k})$, $\kappa_x \bmod \ell^k$ vanishes on $G_{K'}$ iff $x \in (K'^\times)^{\ell^k}$.*

(ii) (Stated.) The Kummer maps $K^\times/(K^\times)^{\ell^k} \to H^1(K,\mu_{\ell^k})$ and $\widehat{K^\times} = \varprojlim_k K^\times/(K^\times)^{\ell^k} \to H^1(K,\mathbb{Z}_\ell(1))$ are isomorphisms. We do not prove this here; it is proved in Chapter 17 from Hilbert's Theorem 90 (see also [174, Chapter XIV]).

(iii) With Theorem 7.20: $H^1(K,\mathbb{Z}_\ell(1)) \simeq \mathbb{Z}_\ell \times \mathbb{Z}/\ell^v$, $v = v_\ell(q-1)$; the projection to $\mathbb{Z}_\ell$ is induced by v_K, the torsion is the image of the units, $\mathbb{F}_q^\times \otimes \mathbb{Z}_\ell \simeq \mathbb{Z}_\ell(1)/(q-1)\mathbb{Z}_\ell(1)$; and $\#H^1(K,\mu_{\ell^k}) = \ell^k \cdot \#\mu_{\ell^k}(K)$.

Proof. (i) Write $\alpha_k = x^{1/\ell^k}$. Then $\sigma(\alpha_k)/\alpha_k \in \mu_{\ell^k}$, compatible in k, and $\sigma\tau(\alpha_k)/\alpha_k = \sigma\big(\tau(\alpha_k)/\alpha_k\big) \cdot \sigma(\alpha_k)/\alpha_k$, which is the cocycle identity written multiplicatively. Each component

factors through the finite extension $K(\mu_{\ell^k}, \alpha_k)$, so κ_x is continuous. Another system is $(\zeta_k \alpha_k)$ with $z = (\zeta_k) \in \mathbb{Z}_\ell(1)$, which adds $\sigma(\zeta_k)/\zeta_k$, that is $(\chi_\ell(\sigma) - 1)z$. The product rule is clear. For $\sigma \in G_{K'}$, σ fixes μ_{ℓ^k}, and $\kappa_x(\sigma) \equiv 0 \pmod{\ell^k}$ means $\sigma(\alpha_k) = \alpha_k$; this holds for all such σ iff $\alpha_k \in K'$; and if $x = y^{\ell^k}$ with $y \in K'$, then $\alpha_k = \zeta y \in K'$ for some $\zeta \in \mu_{\ell^k}$. (iii) combines (ii) with Theorem 7.20(iv), (v). □

Theorem 7.58 (the Kummer cocycle on inertia and on Frobenius)**.** *Let $\ell \neq p$, ϖ a uniformiser of K, $x \in K^\times$, $a = v_K(x)$ and $x = \varpi^a u$ with $u \in \mathcal{O}_K^\times$. Choose compatible systems of ℓ-power roots of ϖ and u, and give x the product system. Put $v = v_\ell(q-1)$.*

(i) $\kappa_x = a\,\kappa_\varpi + \kappa_u$.

(ii) $\kappa_\varpi|_{I_K} = t_\ell$ *and* $\kappa_u|_{I_K} = 0$*; hence*

$$\kappa_x|_{I_K} = v_K(x) \cdot t_\ell,$$

independently of all choices.

(iii) κ_u *is unramified: it factors through G_K/I_K, so it is determined by* $\kappa_u(\mathrm{Frob})$*, which is well defined modulo $(q-1)\mathbb{Z}_\ell(1)$. Under $\mathbb{Z}_\ell(1)/(q-1)\mathbb{Z}_\ell(1) = \mu_{\ell^v}$ its class is the Teichmüller lift of $\bar{u}^{(q-1)/\ell^v}$; that is, it is the class of $\bar{u}$ in $\mathbb{F}_q^\times/(\mathbb{F}_q^\times)^{\ell^v} = \mathbb{F}_q^\times \otimes \mathbb{Z}_\ell$. In particular κ_u is a coboundary iff $\bar{u} \in (\mathbb{F}_q^\times)^{\ell^v}$.*

(iv) If Frob *fixes the chosen roots of ϖ (Corollary 7.49), then* $\kappa_\varpi(\mathrm{Frob}) = 0$ *and* $\kappa_x(\mathrm{Frob}) = \kappa_u(\mathrm{Frob})$*. For any other lift* $\mathrm{Frob}\,\sigma$ *($\sigma \in I_K$),* $\kappa_x(\mathrm{Frob}\,\sigma) = \kappa_x(\mathrm{Frob}) + q\,a\,t_\ell(\sigma)$*. Hence, after identifying $\mathbb{Z}_\ell(1) \simeq \mathbb{Z}_\ell$, the value $c' = \kappa_x(\mathrm{Frob})$ is well defined modulo the ideal $(a, q-1)\mathbb{Z}_\ell = \ell^{\min(v_\ell(a),v)}\mathbb{Z}_\ell$ when the lift and the roots vary, and* $\min(v_\ell(a), v, v_\ell(c'))$ *does not depend on any choice.*

(v) For $k \geq 1$: I_K fixes the ℓ^k-th roots of x iff $\ell^k \mid a$; the image of I_K in $\mathrm{Gal}(K^{\mathrm{ur}}(x^{1/\ell^k})/K^{\mathrm{ur}}) \subseteq \mu_{\ell^k}$ *has order $\ell^{k-\min(k,v_\ell(a))}$. Equivalently, x is an ℓ^k-th power in K^{ur} iff $\ell^k \mid v_K(x)$.*

Proof. (i) is the product rule. (ii) On I_K, κ_ϖ is by definition t_ℓ (Theorem 7.47(iii)). The ℓ^k-th roots of u lie in K^{ur} (Proposition 7.36(iv), with $\mu_{\ell^k} \subset K^{\mathrm{ur}}$), so I_K fixes them and $\kappa_u|_{I_K} = 0$. A cocycle restricted to I_K, on which $\chi_\ell = 1$, is a homomorphism, and coboundaries $(\chi_\ell - 1)z$ vanish on I_K; so the restriction does not depend on the choices. (iii) For $g \in G_K$ and $\sigma \in I_K$, $\kappa_u(g\sigma) = \kappa_u(g) + \chi_\ell(g)\kappa_u(\sigma) = \kappa_u(g)$, so κ_u factors through G_K/I_K; there Frob is a topological generator, and the coboundaries are $(\chi_\ell(\mathrm{Frob}) - 1)z = (q-1)z$. To compute the class, write $u = [\bar{u}]u_1$ with $u_1 \in U^{(1)}$ (Theorem 7.17). Changing roots changes κ_u by a coboundary, so we may take the unique roots of u_1 in $U^{(1)}$ (Theorem 7.20(i)), for which $\kappa_{u_1} = 0$, and roots $\omega_k = [\bar{u}]^{1/\ell^k}$, which are roots of unity of order prime to p. Since Frob acts on such roots of unity by $y \mapsto y^q$, $\kappa_u(\mathrm{Frob}) = (\omega_k^{q-1})_k$. The projection $\mathbb{Z}_\ell(1) \to \mathbb{Z}_\ell(1)/(q-1)\mathbb{Z}_\ell(1) = \mathbb{Z}_\ell(1)/\ell^v\mathbb{Z}_\ell(1) = \mu_{\ell^v}$ is the component at $k = v$, which is $\omega_v^{q-1} = \omega_v^{\ell^v N} = [\bar{u}]^N$ with $N = (q-1)/\ell^v$. Its reduction is $\bar{u}^N$. Finally $y \mapsto y^N$ maps the cyclic group $\mathbb{F}_q^\times$ onto $\mu_{\ell^v}(\mathbb{F}_q)$ with kernel $(\mathbb{F}_q^\times)^{\ell^v}$ (Theorem 7.20(v)). (iv) If Frob fixes the roots of ϖ, $\kappa_\varpi(\mathrm{Frob}) = 0$ and (i) gives $\kappa_x(\mathrm{Frob}) = \kappa_u(\mathrm{Frob})$. The cocycle identity and (ii) give $\kappa_x(\mathrm{Frob}\,\sigma) = \kappa_x(\mathrm{Frob}) + \chi_\ell(\mathrm{Frob})\,a\,t_\ell(\sigma) = \kappa_x(\mathrm{Frob}) + q\,a\,t_\ell(\sigma)$, and t_ℓ is surjective; changing roots adds $(q-1)z$. As q is a unit in $\mathbb{Z}_\ell$, the ambiguity is the ideal $(a, q-1)$, generated by $\ell^{\min(v_\ell(a),v)}$, and changing c' by an element of it does not change $\min(v_\ell(a), v, v_\ell(c'))$. Changing the identification $\mathbb{Z}_\ell(1) \simeq \mathbb{Z}_\ell$ multiplies c' by a unit. (v) By (ii), $\sigma \in I_K$ moves x^{1/ℓ^k}

by $\zeta^{a\,t(\sigma)}$, with ζ a generator of μ_{ℓ^k} and $t(\sigma) \in \mathbb{Z}/\ell^k$ the image of $t_\ell(\sigma)$; as t_ℓ is surjective, the image of I_K is the subgroup of μ_{ℓ^k} generated by ζ^a, of order $\ell^{k-\min(k,v_\ell(a))}$, which is trivial iff $\ell^k \mid a$. The last statement is also Proposition 7.36(iv). □

A small case shows (iii) at work. Take $K = \mathbb{Q}_7$, $\ell = 3$, so $v = v_3(6) = 1$ and $N = (q-1)/\ell^v = 2$, and $x = u = 2$. Then $\bar{u}^N = 4$, a primitive cube root of unity in $\mathbb{F}_7$ ($4^3 = 64 \equiv 1$), so the class of κ_2 in $\mathbb{Z}_3(1)/(q-1)\mathbb{Z}_3(1) \simeq \mu_3$ is nontrivial: κ_2 is not a coboundary, and 2 is not a cube in $\mathbb{Q}_7$, in agreement with Example 7.22(a). For $x = u = 6$ instead, $\bar{u}^N = 36 \equiv 1$, and κ_6 is a coboundary, matching the fact that $6 \equiv -1 = (-1)^3$ is a cube.

In the paper 7.59. *Lemma lem:tamagawa-exp.* Over $\mathbb{Q}_q^{\mathrm{ur}}$ (or already over the unramified quadratic extension, where the curve is a Tate curve) the ℓ^t-torsion is generated by μ_{ℓ^t} and an ℓ^t-th root of q_E, and inertia acts trivially on $E[\ell^t]$ iff it fixes that root, iff $\ell^t \mid v_q(q_E) = n_q$ by Theorem 7.58(v). This is the precise form of the paper's statement that q_E is an ℓ^t-th power in $\mathbb{Q}_q^{\mathrm{ur}}$ if and only if $\ell^t \mid n_q$. *Lemma lem:tamfactor.* "the restriction of κ to I is n times the tame character" is Theorem 7.58(ii) with $x = q_E$, $a = n$. "$\kappa = n\kappa_q + \kappa_u$, where κ_u is unramified, inflated from the class of u" is (i) and (iii) with $\varpi = q$. "$c' = \varepsilon\kappa(\mathrm{Frob})$ is a cocycle value: it is ε times the class of u for the Frobenius lift fixing a compatible system of ℓ-power roots of q, and in general it is well defined only modulo $\ell^{\min(v_\ell(n),v_\ell(q-1))}$" is (iii) and (iv), together with Corollary 7.49; the factor ε is the twist of Example 7.74. The identification of the class in $H^1(G/I, \mathbb{Z}_\ell(1))$ with the class of $\bar{u}$ is (iii); its cohomological meaning is Chapter 17.

7.6.1 Quadratic extensions and quadratic characters

Proposition 7.60 (quadratic extensions of $\mathbb{Q}_p$)**.** *(i) Let p be odd and $u_0 \in \mathbb{Z}_p^\times$ a non-square. $\mathbb{Q}_p$ has exactly three quadratic extensions: the unramified $\mathbb{Q}_p(\sqrt{u_0}) = \mathbb{Q}_p(\mu_{p^2-1})$ and the ramified $\mathbb{Q}_p(\sqrt{p})$, $\mathbb{Q}_p(\sqrt{u_0 p})$, both tamely ramified. The field $\mathbb{Q}_p(\sqrt{p^*})$ is $\mathbb{Q}_p(\sqrt{p})$ if $p \equiv 1 \pmod 4$ and $\mathbb{Q}_p(\sqrt{-p}) = \mathbb{Q}_p(\sqrt{u_0 p})$ if $p \equiv 3 \pmod 4$.*

(ii) Let p be odd. The quadratic characters of $G_{\mathbb{Q}_p}$ are 1, the unramified η_{ur} ($\eta_{\mathrm{ur}}(\mathrm{Frob}) = -1$) and two ramified ones χ, $\chi\eta_{\mathrm{ur}}$. Every ramified one restricts on I_p to the unique character of order 2 of I_p, which is $\theta_2 \colon \sigma \mapsto \sigma(\sqrt{p})/\sqrt{p}$.

(iii) $\mathbb{Q}_2$ has seven quadratic extensions, $\mathbb{Q}_2(\sqrt{d})$ for $d \in \{-1, \pm 5, \pm 2, \pm 10\}$. The unramified one is $\mathbb{Q}_2(\sqrt{5}) = \mathbb{Q}_2(\sqrt{-3})$; the others are wildly ramified, $\mathbb{Q}_2(\sqrt{-1})$ and $\mathbb{Q}_2(\sqrt{-5}) = \mathbb{Q}_2(\sqrt{3})$ with lower ramification jump 1, and $\mathbb{Q}_2(\sqrt{\pm 2})$, $\mathbb{Q}_2(\sqrt{\pm 10})$ with jump 2 (Example 7.43).

Proof. By Kummer theory for $n = 2$ (Chapter 5), quadratic extensions of $\mathbb{Q}_p$ correspond to the nontrivial elements of $\mathbb{Q}_p^\times/(\mathbb{Q}_p^\times)^2$, through $d \mapsto \mathbb{Q}_p(\sqrt{d})$, and quadratic characters to the same group (the character of $\mathbb{Q}_p(\sqrt{d})$ being $\sigma \mapsto \sigma(\sqrt{d})/\sqrt{d}$). (i) By Theorem 7.20(vi) the nontrivial classes are u_0, p, $u_0 p$. The residue field $\mathbb{F}_{p^2}$ of $\mathbb{Q}_p(\mu_{p^2-1})$ (Theorem 7.34) contains a square root of $\bar{u}_0$, so u_0 is a square there (Theorem 7.20(ii)), and $\mathbb{Q}_p(\sqrt{u_0}) = \mathbb{Q}_p(\mu_{p^2-1})$ is unramified. $X^2 - p$ and $X^2 - u_0 p$ are Eisenstein. If $p \equiv 3 \pmod 4$, -1 is not a square modulo p, so $-p \in u_0 p(\mathbb{Q}_p^\times)^2$. Ramification index 2 is prime to p. (ii) A quadratic character is unramified iff its field is, and η_{ur} is the character of the unramified extension, on whose group Frob acts nontrivially. A ramified quadratic character is nontrivial on I_p. A character of order 2 of I_p is continuous with finite image, so it kills the pro-p group P_p (p odd), and factors through the procyclic $I_p/P_p \simeq \prod_{\ell \neq p} \mathbb{Z}_\ell(1)$, which has exactly one quotient of order 2; and θ_2 (Theorem 7.47, $m = 2$, $\varpi = p$) is such a character. (iii) $\mathbb{Q}_2^\times/(\mathbb{Q}_2^\times)^2$ has order 8 with representatives $\pm 1, \pm 5, \pm 2, \pm 10$ (Theorem 7.20(vi)).

$\alpha = (1+\sqrt{5})/2$ is a root of $X^2 - X - 1 \in \mathbb{Z}_2[X]$, so it lies in the ring of integers of $L = \mathbb{Q}_2(\sqrt{5})$, and its reduction is a root of $X^2 + X + 1$, which is irreducible over $\mathbb{F}_2$. So the residue field of L contains $\mathbb{F}_4$, $f(L/\mathbb{Q}_2) = 2 = [L : \mathbb{Q}_2]$, $e(L/\mathbb{Q}_2) = 1$ and L is unramified (Theorem 7.25); and $-3 \cdot 5 = -15 \equiv 1 \pmod 8$ and $3 \cdot (-5) \equiv 1 \pmod 8$ are squares, so $\mathbb{Q}_2(\sqrt{-3}) = \mathbb{Q}_2(\sqrt{5})$ and $\mathbb{Q}_2(\sqrt{3}) = \mathbb{Q}_2(\sqrt{-5})$. There is only one unramified quadratic extension, so the other six are ramified, of degree 2, hence wild; the jumps are Example 7.43. □

Proposition 7.61 (global quadratic characters locally)**.** *Let d be a fundamental discriminant and χ_d the character of $\mathbb{Q}(\sqrt{d})$ (Chapter 5). Through Proposition 7.32, $\chi_d|_{G_{\mathbb{Q}_p}}$ is the character of $\mathbb{Q}_p(\sqrt{d})$.*

(i) χ_d is unramified at p iff $p \nmid d$, and then $\chi_d(\mathrm{Frob}_p) = \left(\frac{d}{p}\right)$ (Chapter 6).

(ii) For an odd prime q: at every $p \neq q$, including $p = 2$, χ_{q^*} is unramified, with $\chi_{q^*}(\mathrm{Frob}_p) = \left(\frac{p}{q}\right)$; at q it is ramified and tame, and $\chi_{q^*}|_{I_q} = \theta_2$.

(iii) χ_{-3} at 3 is tamely ramified; χ_{-4} at 2 and χ_8, χ_{-8} at 2 are wildly ramified, with ramification jumps 1 and 2.

(iv) For a finite set S of odd primes, $\chi_S = \prod_{q\in S} \chi_{q^*}$ is unramified outside S and restricts to θ_2 on I_q for each $q \in S$.

(v) For any representation ρ of $G_{\mathbb{Q}}$ and odd q: $(\rho \otimes \chi_{q^*})|_{I_p} = \rho|_{I_p}$ for $p \neq q$, and $(\rho \otimes \chi_{q^*})|_{I_q} = \rho|_{I_q} \otimes \theta_2$. So twisting by χ_{q^*} changes nothing on inertia at $p \neq q$ (the image of inertia, V^{I_p}, the conductor exponent), multiplies Frobenius there by the sign $\chi_{q^*}(\mathrm{Frob}_p)$, and at q multiplies the action of inertia by the character θ_2.

(vi) Every quadratic character of $G_{\mathbb{Q}_p}$ is the restriction of a product of characters χ_d: for p odd, of 1, χ_{d_0}, χ_{p^*} or $\chi_{d_0}\chi_{p^*}$, where d_0 is a fundamental discriminant prime to p with $\left(\frac{d_0}{p}\right) = -1$; for $p = 2$, of a product of χ_{-4}, χ_8 and χ_5.

Proof. The local statement follows from the definitions: $\sigma(\sqrt{d}) = \chi_d(\sigma)\sqrt{d}$ for $\sigma \in G_{\mathbb{Q}}$, and the embedding ι of Proposition 7.32 transports this to $\mathbb{Q}_p(\sqrt{d})$. (i) For p odd, d is p times a unit or a unit, according as $p \mid d$ or not; in the first case $X^2 - d$ is Eisenstein, in the second $\mathbb{Q}_p(\sqrt{d})$ is trivial or unramified (Proposition 7.60(i)). For $p = 2$, a fundamental discriminant is $\equiv 1 \pmod 4$ (odd) or divisible by 4; if $d \equiv 1 \pmod 8$ the field is trivial, if $d \equiv 5 \pmod 8$ it is $\mathbb{Q}_2(\sqrt{5})$, unramified, and if $4 \mid d$ then $d/4 \equiv 2, 3 \pmod 4$ and $\mathbb{Q}_2(\sqrt{d}) = \mathbb{Q}_2(\sqrt{d/4})$ is one of the six ramified fields (Proposition 7.60(iii)). The value at Frob_p is Chapter 6. (ii) $q^* \equiv 1 \pmod 4$, so (i) applies; $(q^*/p) = (p/q)$ is quadratic reciprocity (Chapter 6). At q, χ_{q^*} is ramified and q is odd, so Proposition 7.60(ii) gives θ_2. (iii) $\mathbb{Q}_3(\sqrt{-3})$ is tame (Proposition 7.28(ii)); $\mathbb{Q}_2(\sqrt{-1})$, $\mathbb{Q}_2(\sqrt{\pm 2})$ are Example 7.43. (iv) and (v) follow from (ii), since a character is trivial on I_p where it is unramified. (vi) By Proposition 7.60 the classes in $\mathbb{Q}_p^\times/(\mathbb{Q}_p^\times)^2$ are represented by $1, d_0, p^*, d_0p^*$ for p odd (d_0 is a non-square unit; such a d_0 exists: -4 if $p \equiv 3 \pmod 4$, 8 if $p \equiv 5 \pmod 8$, and in general a prime $d_0 \equiv 1 \pmod 4$ that is a quadratic non-residue modulo p, which exists by Dirichlet's theorem, a case of Chebotarev's, Chapter 6), and are generated by -1, 2, 5 for $p = 2$; the characters of $\mathbb{Q}_2(\sqrt{-1})$, $\mathbb{Q}_2(\sqrt{2})$, $\mathbb{Q}_2(\sqrt{5})$ are the restrictions of χ_{-4}, χ_8, χ_5. □

Theorem 7.62 (local class field theory for $\mathbb{Q}_p$)**.** *(i) (Local Kronecker-Weber.) The maximal abelian extension of $\mathbb{Q}_p$ is $\mathbb{Q}_p^{\mathrm{ab}} = \mathbb{Q}_p^{\mathrm{ur}} \cdot \mathbb{Q}_p(\mu_{p^\infty})$.*

(ii) There is a unique continuous homomorphism $\mathrm{Art}\colon \mathbb{Q}_p^\times \to \mathrm{Gal}(\mathbb{Q}_p^{\mathrm{ab}}/\mathbb{Q}_p)$ *such that* $\mathrm{Art}(p)$ *is the arithmetic Frobenius on* $\mathbb{Q}_p^{\mathrm{ur}}$ *and the identity on* $\mathbb{Q}_p(\mu_{p^\infty})$*, and, for* $u \in \mathbb{Z}_p^\times$*,* $\mathrm{Art}(u)$ *is the identity on* $\mathbb{Q}_p^{\mathrm{ur}}$ *and acts on* μ_{p^∞} *by* $\zeta \mapsto \zeta^{u^{-1}}$*. It is injective with dense image,* $\mathrm{Art}(\mathbb{Z}_p^\times)$ *is the image of* I_p*, and* $\mathrm{Art}(1+p^n\mathbb{Z}_p)$ *is the image of the upper ramification group* $G^n_{\mathbb{Q}_p}$ *(*$n \geq 1$*).*

(iii) For a character χ *of* $G_{\mathbb{Q}_p}$ *of finite order, its Artin conductor exponent* $a(\chi)$ *(Definition 7.81) is the least* $n \geq 0$ *with* $\chi(\mathrm{Art}(U^{(n)})) = 1$*, where* $U^{(0)} = \mathbb{Z}_p^\times$ *and* $U^{(n)} = 1+p^n\mathbb{Z}_p$*. For a Dirichlet character* χ *(Chapter 6) the product of the* $p^{a(\chi|_{G_{\mathbb{Q}_p}})}$ *is the conductor of* χ*.*

We do not prove this; see Serre's chapter "Local class field theory" in Cassels and Fröhlich [26], Milne [133, Chapter I], and Neukirch [142, Chapter V].

Warning 7.63 (normalisations of the Artin map). The book's Artin map sends a uniformiser to an *arithmetic* Frobenius, as in Chapter 6; units then act on μ_{p^∞} through u^{-1}. Deligne [41] and many sources on Weil-Deligne representations send uniformisers to geometric Frobenius elements, and units act through u. The book never needs the other normalisation, and uses local class field theory only for the conductors of characters, Theorem 7.62(iii). For example, χ_{-4} is trivial on $\mathrm{Art}(1+4\mathbb{Z}_2)$ but not on $\mathrm{Art}(\mathbb{Z}_2^\times)$, so $a(\chi_{-4}|_{G_{\mathbb{Q}_2}}) = 2$; χ_8 is trivial on $\mathrm{Art}(1+8\mathbb{Z}_2)$ but not on $\mathrm{Art}(1+4\mathbb{Z}_2)$, so $a = 3$; these agree with Theorem 7.82(iv) and with the conductors 4 and 8.

7.7 The Weil group and Weil-Deligne representations

An ℓ-adic representation of G_K ($\ell \neq p$) can have infinite image of inertia, as the Tate module of a curve with multiplicative reduction does; Grothendieck's theorem says that this infinite part is always unipotent, given by a nilpotent "monodromy" operator N. Recording the finite part r and N separately gives the Weil-Deligne representation, in terms of which the local invariants (V^I, L-factors, conductors) are computed in Sections 7.8 and 7.9, independently of ℓ. The paper speaks of "local components" and the "unramified twist of the Steinberg representation" in Lemmas lem:twist(iii) and lem:euler; on the Galois side these are the Weil-Deligne representations $\mathrm{sp}(2) \otimes \mu$ of this section (the automorphic side is Chapter 15).

Convention 7.64 (the norm on the Weil group)**.** For w in the Weil group W_K (Definition 7.65), $d(w) \in \mathbb{Z}$ is defined by $w|_{K^{\mathrm{ur}}} = \mathrm{Frob}^{d(w)}$, and $\|w\| = q^{d(w)}$. So $\|\mathrm{Frob}\| = q$, $\|\Phi\| = q^{-1}$, $\|\cdot\|$ is trivial on I_K, and $\|w\| = \chi_\ell(w)$ for every $\ell \neq p$. A Weil-Deligne representation satisfies

$$r(w)\,N\,r(w)^{-1} = \|w\|\,N, \qquad \text{that is} \qquad r(\mathrm{Frob})\,N\,r(\mathrm{Frob})^{-1} = q\,N, \quad r(\Phi)\,N\,r(\Phi)^{-1} = q^{-1}N.$$

Some sources write $\mathrm{Frob}\,N\,\mathrm{Frob}^{-1} = q^{-1}N$ with Frob geometric; here Frob is arithmetic (Appendix B, convention B-C2(f)). This $\|\cdot\|$ agrees with Tate's normalisation in [194].

Definition 7.65 (the Weil group)**.** The *Weil group* of K is $W_K = \{w \in G_K : \ w|_{K^{\mathrm{ur}}} \in \mathrm{Frob}^{\mathbb{Z}}\}$, the preimage of the subgroup $\mathbb{Z} \subset \hat{\mathbb{Z}} \simeq \mathrm{Gal}(K^{\mathrm{ur}}/K)$. It is given the topology in which I_K, with its profinite topology, is an open subgroup.

Proposition 7.66. *(i)* W_K *is a dense subgroup of* G_K *containing* I_K*, with* $W_K/I_K \simeq \mathbb{Z}$ *generated by the image of* Frob*; its topology is finer than the topology induced from* G_K*, and every* $w \in W_K$ *is uniquely* $w = \Phi^n\sigma$ *with* $n \in \mathbb{Z}$*,* $\sigma \in I_K$*, for a fixed geometric Frobenius lift* $\Phi \in W_K$*.*

(ii) $d\colon W_K \to \mathbb{Z}$ *is a continuous homomorphism,* $\|\mathrm{Frob}\| = q$, $\|\Phi\| = q^{-1}$, *and* $\|w\| = \chi_\ell(w)$ *for* $\ell \neq p$.

(iii) A homomorphism $\mu\colon W_K \to \Omega^\times$ *trivial on* I_K *(an* unramified character*) is determined by* $\mu(\Phi)$*, which may be any element of* $\Omega^\times$*;* $\|\cdot\|$ *is the unramified character with* $\Phi \mapsto q^{-1}$*. A character of* G_K *with values in* $\mathbb{Q}_\ell^\times$ *takes values in* $\mathbb{Z}_\ell^\times$*, but a character of* W_K *need not.*

(iv) (Stated.) The Artin map of Theorem 7.62 identifies $\mathbb{Q}_p^\times$ *with* $W_{\mathbb{Q}_p}^{\mathrm{ab}}$*, and* $\|\mathrm{Art}(x)\| = |x|_p^{-1}$.

Proof. (i) The restriction $G_K \to \hat{\mathbb{Z}}$ is open and surjective, and $\mathbb{Z}$ is dense in $\hat{\mathbb{Z}}$, so the preimage W_K is dense; I_K is the kernel. Open subsets of I_K are open in W_K by definition, and a subset of W_K open in the induced topology is a union of cosets of open subsets of I_K; so the topology is finer. A lift Φ maps to $-1 \in \mathbb{Z}$, a generator. (ii) d is the composite $W_K \to W_K/I_K \simeq \mathbb{Z}$, continuous because I_K is open; χ_ℓ is unramified with $\chi_\ell(\mathrm{Frob}) = q$ (Proposition 7.39). (iii) $W_K/I_K \simeq \mathbb{Z}$ is free on the image of Φ. A continuous character of the compact group G_K has compact image in $\mathbb{Q}_\ell^\times$; its image under v_ℓ is a compact subgroup of $\mathbb{Z}$, hence 0, so the image lies in $\mathbb{Z}_\ell^\times$. The unramified character of W_K with $\Phi \mapsto \ell$ does not. □

Lemma 7.67 (matrix logarithm)**.** *Let* $\mathcal{O}$ *be the ring of integers of a finite extension* E_λ *of* $\mathbb{Q}_\ell$ *and* $\mathfrak{g} = \ell^2\,\mathrm{M}_n(\mathcal{O})$*. Then* $\exp(X) = \sum X^k/k!$ *converges for* $X \in \mathfrak{g}$ *and* $\log(g) = \sum_{k\geq 1}(-1)^{k+1}(g-1)^k/k$ *for* $g \in 1+\mathfrak{g}$*; they are mutually inverse bijections* $\mathfrak{g} \leftrightarrows 1+\mathfrak{g}$*;* $\exp(X+Y) = \exp X \exp Y$ *when* $XY = YX$*; and* $g^a = \exp(a \log g)$ *for* $a \in \mathbb{Z}_\ell$*, where* $g^a = \lim g^{a_k}$ *for integers* $a_k \to a$*. For nilpotent* N *the series* $\exp(tN)$ *is a polynomial in* t *and* $\log\exp(tN) = tN$ *for all* $t \in E_\lambda$.

Proof. Use $\|X\| = \max|x_{ij}|_\ell$, which satisfies $\|XY\| \leq \|X\|\|Y\|$ (ultrametric inequality), and the estimates in the proof of Theorem 7.18 with $c = 2$: the terms are of valuation $\geq 2k - (k-1) = k+1 \geq 2$, so both series converge into $\mathfrak{g}$, resp. $1+\mathfrak{g}$. The identities hold in $\mathbb{Q}[[X,Y]]$ (for commuting variables) and transfer, entry by entry, by Lemma 7.4 with the same bounds, all the matrices involved commuting. For $a \in \mathbb{Z}$, $\exp(a\log g) = \exp(\log g)^a = g^a$; both sides are continuous in a (the left side by the bounds, the right side because $g^{\ell^k} \to 1$ in the pro-ℓ group $1+\mathfrak{g}$), so they agree on $\mathbb{Z}_\ell$. For nilpotent N the series are finite and the identity is a polynomial identity. □

Theorem 7.68 (Grothendieck's ℓ-adic monodromy theorem)**.** *Let* $\ell \neq p$*,* E_λ *a finite extension of* $\mathbb{Q}_\ell$*,* V *a finite-dimensional* E_λ*-vector space and* $\rho\colon G_K \to \mathrm{GL}(V)$ *continuous. Fix a generator* ζ *of* $\mathbb{Z}_\ell(1)$ *and let* $t_\zeta\colon I_K \to \mathbb{Z}_\ell$ *be the tame character followed by* $\zeta \mapsto 1$*. There are an open subgroup* $I_1 \subseteq I_K$*, normal in* G_K*, and a unique nilpotent* $N \in \mathrm{End}(V)$ *with*

$$\rho(\sigma) = \exp\bigl(t_\zeta(\sigma)N\bigr) \qquad \text{for all } \sigma \in I_1,$$

and $\rho(w)\,N\,\rho(w)^{-1} = \|w\|\,N$ *for all* $w \in W_K$*; in particular* $\rho(\mathrm{Frob})N\rho(\mathrm{Frob})^{-1} = qN$*. Moreover* $N = 0$ *iff* $\rho(I_K)$ *is finite, and replacing* ζ *by* ζ^a *(*$a \in \mathbb{Z}_\ell^\times$*) replaces* N *by* aN.

Proof. $\rho(G_K)$ is compact, so it stabilises a lattice T (the stabiliser of any lattice T_0 is open, and the sum of the finitely many translates $\rho(g)T_0$ is stable); in a basis of T, $\rho\colon G_K \to \mathrm{GL}_n(\mathcal{O})$. Let $I_1 = I_K \cap \rho^{-1}(1+\ell^2\,\mathrm{M}_n(\mathcal{O}))$, open in I_K and normal in G_K. By Proposition 7.53(i), $\rho|_{I_1} = \phi \circ t_\zeta|_{I_1}$ for a homomorphism $\phi\colon t_\zeta(I_1) \to 1+\ell^2\,\mathrm{M}_n(\mathcal{O})$, continuous because $t_\zeta|_{I_1}$ is a quotient map of compact groups. The image $t_\zeta(I_1)$ is a closed subgroup of finite index of $\mathbb{Z}_\ell$, so $t_\zeta(I_1) = \ell^m\mathbb{Z}_\ell$. Choose $\sigma_1 \in I_1$ with $t_\zeta(\sigma_1) = \ell^m$, put $g = \rho(\sigma_1)$ and $N = \ell^{-m}\log g$ (Lemma 7.67). For $\sigma \in I_1$

with $t_\zeta(\sigma) = \ell^m b$, $b \in \mathbb{Z}_\ell$, continuity of ϕ gives $\rho(\sigma) = \phi(\ell^m)^b = g^b = \exp(b \log g) = \exp(t_\zeta(\sigma)N)$. For $w \in W_K$, $w\sigma_1 w^{-1} \in I_1$ and $t_\zeta(w\sigma_1 w^{-1}) = \chi_\ell(w)\ell^m = \|w\|\ell^m$ (Theorem 7.50(i)); hence

$$\exp(\rho(w) \log g\, \rho(w)^{-1}) = \rho(w) g \rho(w)^{-1} = \rho(w\sigma_1 w^{-1}) = \exp(\|w\| \log g).$$

Both arguments of exp lie in $\ell^2 \operatorname{M}_n(\mathcal{O})$ ($\rho(w) \in \operatorname{GL}_n(\mathcal{O})$, and $\|w\| \in \mathbb{Z}_\ell^\times$), where exp is injective; so $\rho(w) N \rho(w)^{-1} = \|w\| N$. In particular N is conjugate to qN, so the finite set of eigenvalues of N (in an algebraic closure) is stable under multiplication by q; as $q^i \neq q^j$ for $i \neq j$, all eigenvalues are 0 and N is nilpotent. Uniqueness: if N' is nilpotent with $\rho = \exp(t_\zeta N')$ on an open I_1', pick $\sigma \in I_1 \cap I_1'$ with $t_\zeta(\sigma) = \ell^{m'} \neq 0$; then $\ell^{m'} N = \log \rho(\sigma) = \ell^{m'} N'$ by Lemma 7.67. If $N = 0$ then $\rho(I_1) = 1$ and $\rho(I_K)$ is finite. If $\rho(I_K)$ is finite, g has finite order and $\log(g^k) = k \log g$, so $\log g = 0$ and $N = 0$. Finally $t_{\zeta^a} = a^{-1} t_\zeta$, so $\exp(t_\zeta(\sigma)N) = \exp(t_{\zeta^a}(\sigma)\, aN)$. □

The theorem says that N is the logarithm of the monodromy: just as a unipotent matrix u is $\exp(\log u)$ with $\log u$ nilpotent, the action of an open subgroup of inertia is exp of a multiple of N. The same statement holds for continuous representations of W_K (Deligne [41, Section 8]); we need only G_K.

Definition 7.69 (Weil-Deligne representations)**.** Let Ω be a field of characteristic 0. A *Weil-Deligne representation* of W_K over Ω is a pair (r, N) on a finite-dimensional Ω-vector space V: a homomorphism $r\colon W_K \to \operatorname{GL}(V)$ whose restriction to I_K has open kernel (so $r(I_K)$ is finite), and a nilpotent $N \in \operatorname{End}(V)$ with $r(w) N r(w)^{-1} = \|w\| N$ for all $w \in W_K$. A morphism is a linear map commuting with r and N. (r, N) is *Frobenius-semisimple* if $r(\Phi)$ is semisimple.

Proposition 7.70 (operations on Weil-Deligne representations)**.** *If (r, N, V) and (r', N', V') are Weil-Deligne representations, so are: $V \oplus V'$ with $N \oplus N'$; $V \otimes V'$ with $N \otimes 1 + 1 \otimes N'$; the dual $V^\vee$ with $r^\vee(w) = r(w^{-1})^{\mathsf{T}}$ and $-N^{\mathsf{T}}$; $\operatorname{Hom}(V, V')$ with $f \mapsto N'f - fN$; in particular $\operatorname{End} V$ and its trace-zero part $\operatorname{ad}^0 V$ with $N_{\operatorname{ad}^0} = [N, \cdot\,]$; and the twist $V \otimes \mu$ by a character μ of W_K (with N unchanged). The kernel $\ker N$ and the invariants $V^{r(I_K)}$ are stable under $r(W_K)$. (Stated.) Every (r, N) has a Frobenius-semisimplification, obtained by replacing $r(\Phi^n\sigma)$ by $r(\Phi)^n_{\mathrm{ss}} r(\sigma)$; see [41, Section 8], [194, Section 4.1].*

Proof. Each relation is a one-line check. For example $(r \otimes r')(w)(N \otimes 1 + 1 \otimes N')(r \otimes r')(w)^{-1} = \|w\| N \otimes 1 + 1 \otimes \|w\| N'$; for the dual, $r(w^{-1})^{\mathsf{T}}(-N^{\mathsf{T}}) r(w)^{\mathsf{T}} = -(r(w) N r(w)^{-1})^{\mathsf{T}}$; and for ad^0, $r(w)[N, x] r(w)^{-1} = \|w\| [N, r(w) x r(w)^{-1}]$. Nilpotency is clear in each case ($N \otimes 1$ and $1 \otimes N'$ commute). If $Nv = 0$ then $N r(w) v = \|w\|^{-1} r(w) N v = 0$; and I_K is normal in W_K. □

Theorem 7.71 (the Weil-Deligne representation of an ℓ-adic representation)**.** *Let ρ, ζ, N be as in Theorem 7.68, and fix a geometric Frobenius lift $\Phi \in W_K$. Put*

$$r(\Phi^n \sigma) = \rho(\Phi^n \sigma) \exp(-t_\zeta(\sigma) N) \qquad (n \in \mathbb{Z},\ \sigma \in I_K).$$

(i) $\operatorname{WD}(\rho) = (r, N)$ *is a Weil-Deligne representation over E_λ; $r = \rho$ on Φ, and r is trivial on I_1.*

(ii) Its isomorphism class does not depend on Φ or on ζ.

(iii) (Stated.) $\rho \mapsto \operatorname{WD}(\rho)$ is an equivalence between continuous representations of W_K on finite-dimensional E_λ-spaces and Weil-Deligne representations over E_λ; those coming from G_K are the ones for which the eigenvalues of $r(\Phi)$ are ℓ-adic units. It is compatible with $\oplus$, $\otimes$, duals, ad^0 and twists by characters; $\mathbb{Q}_\ell(1)$ goes to $(\|\cdot\|, 0)$.

(iv) (Stated.) For the Tate module $V_\ell E$ of an elliptic curve over K, the Frobenius semisimplification of $\mathrm{WD}(V_\ell E)$, viewed over an algebraic closure of $\mathbb{Q}_\ell$, is defined over $\mathbb{Q}$ and does not depend on $\ell \neq p$ (Chapter 11, Chapter 15).

Proof. (i) $\exp(-tN)$ is defined for all $t \in \mathbb{Z}_\ell$ (N nilpotent). Let $w = \Phi^n\sigma$, $w' = \Phi^{n'}\sigma'$; then $ww' = \Phi^{n+n'}\sigma''\sigma'$ with $\sigma'' = \Phi^{-n'}\sigma\Phi^{n'}$, and $t_\zeta(\sigma'') = \chi_\ell(\Phi^{-n'})t_\zeta(\sigma) = q^{n'}t_\zeta(\sigma)$ by Theorem 7.50(i). The relation $\rho(w')^{-1}N\rho(w') = \|w'\|^{-1}N = q^{n'}N$ gives $\exp(-tN)\rho(w') = \rho(w')\exp(-tq^{n'}N)$, so

$$r(w)r(w') = \rho(w)\rho(w')\exp(-q^{n'}t_\zeta(\sigma)N)\exp(-t_\zeta(\sigma')N) = \rho(ww')\exp(-t_\zeta(\sigma''\sigma')N) = r(ww').$$

On I_1, $\rho(\sigma) = \exp(t_\zeta(\sigma)N)$, so $r(\sigma) = 1$; the kernel of $r|_{I_K}$ is open. $r(w)Nr(w)^{-1} = \rho(w)N\rho(w)^{-1} = \|w\|N$, as $\exp(tN)$ commutes with N. (ii) Changing ζ to ζ^a leaves r unchanged and replaces N by aN. Let $k \geq 1$ be such that conjugation by $r(\Phi^k)$ is trivial on the finite group $r(I_K)$ (it is an automorphism of finite order). Then $r(\Phi^k)$ commutes with $r(W_K)$, so its generalised eigenspaces V_λ are $r(W_K)$-stable, and $N(V_\lambda) \subseteq V_{q^{-k}\lambda}$ because $r(\Phi^k)N = q^{-k}Nr(\Phi^k)$. Choose a representative λ_0 in each orbit of $q^{k\mathbb{Z}}$ on the eigenvalues and let A act on $V_{\lambda_0 q^{-kj}}$ by a^j. Then A commutes with $r(W_K)$ and $ANA^{-1} = aN$, so $(r, N) \simeq (r, aN)$. Here the eigenvalues lie in a finite Galois extension F of E_λ, and A is first defined on $V \otimes F$; it is defined over E_λ if the representatives are chosen compatibly with $\mathrm{Gal}(F/E_\lambda)$. This is possible: if $\gamma \in \mathrm{Gal}(F/E_\lambda)$ maps an orbit to itself, then $\gamma(\lambda_0) = \lambda_0 q^{-kj}$ for some j, and since γ has finite order m, $\lambda_0 = \gamma^m(\lambda_0) = \lambda_0 q^{-kjm}$, so $j = 0$. Choosing one λ_0 in each $\mathrm{Gal}(F/E_\lambda)$-orbit of orbits and $\gamma(\lambda_0)$ for its transforms is therefore well defined, and then γ maps $V_{\lambda_0 q^{-kj}} \otimes F$ semilinearly onto $V_{\gamma(\lambda_0)q^{-kj}} \otimes F$, so A commutes with $\mathrm{Gal}(F/E_\lambda)$ and descends to E_λ (as $a \in \mathbb{Z}_\ell^\times \subseteq E_\lambda$). If Φ is replaced by $\Phi' = \Phi\sigma_0$ ($\sigma_0 \in I_K$), write $\Phi'^n = \Phi^n\tau_n$ with $\tau_n \in I_K$ and put $c_n = t_\zeta(\tau_n)$. From $\Phi'^{n+1} = \Phi^n\tau_n\Phi\sigma_0 = \Phi^{n+1}(\Phi^{-1}\tau_n\Phi)\sigma_0$ and $t_\zeta(\Phi^{-1}\tau_n\Phi) = \chi_\ell(\Phi^{-1})c_n = qc_n$ (Theorem 7.50(i)) we get $c_{n+1} = qc_n + t_\zeta(\sigma_0)$, with $c_0 = 0$; this recursion determines c_n for all $n \in \mathbb{Z}$ (it can be run backwards), and $c_n = t_\zeta(\sigma_0)\frac{q^n-1}{q-1}$ satisfies it. For $w = \Phi'^n\sigma = \Phi^n\tau_n\sigma$ the two definitions give $r'(w) = \rho(w)\exp(-t_\zeta(\sigma)N)$ and $r(w) = \rho(w)\exp(-(c_n + t_\zeta(\sigma))N)$, so $r'(w) = r(w)\exp(t_\zeta(\sigma_0)\frac{q^n-1}{q-1}N)$. Put $c = t_\zeta(\sigma_0)/(q-1) \in \mathbb{Q}_\ell$ and $B = \exp(-cN)$, which commutes with N. Since $\|w\| = q^{-n}$, $r(w)^{-1}Nr(w) = q^nN$, hence $r(w)^{-1}\exp(cN)r(w) = \exp(cq^nN)$ and

$$B^{-1}r(w)B = r(w)\cdot r(w)^{-1}\exp(cN)r(w)\cdot\exp(-cN) = r(w)\exp\big(c(q^n-1)N\big) = r'(w);$$

so B is an isomorphism $(r', N) \simeq (r, N)$. (iii), (iv) We do not prove these; see Deligne [41, Section 8], Tate [194, Section 4.2] and Rohrlich [166]; (iv) for elliptic curves follows from the description of $V_\ell E$ in Chapters 10 and 11. □

Definition 7.72 (the special representations)**.** For $n \geq 1$, $\mathrm{sp}(n)$ is the Weil-Deligne representation on $V = \bigoplus_{i=0}^{n-1}\Omega e_i$ with $r(w)e_i = \|w\|^i e_i$ and $Ne_i = e_{i+1}$ ($e_n := 0$). For a character μ of W_K, $\mathrm{sp}(n)\otimes\mu$ is the *special* (or *Steinberg*) representation twisted by μ; for $n = 2$ and μ unramified it is an *unramified twist of Steinberg*, and for μ ramified a *ramified twist*.

Proposition 7.73. *(i) $\mathrm{sp}(n)\otimes\mu$ is an indecomposable Weil-Deligne representation. On $\mathrm{sp}(2)$, Φ acts on e_0, e_1 by $1, q^{-1}$ and Frob by $1, q$, and $\ker N = \Omega e_1$.*

(ii) If $\dim V = 2$ and $N \neq 0$, then (r, N) is automatically Frobenius-semisimple, and $(r, N) \simeq \mathrm{sp}(2)\otimes\mu$ for a unique character μ of W_K, namely the character by which W_K acts on $V/\ker N$.

(iii) (Stated.) A Frobenius-semisimple $(r,0)$ of dimension 2 is a sum of two characters or irreducible; an irreducible one is induced from a character of $W_{K'}$ for a quadratic K'/K, except possibly when $p=2$. See [194, Section 4.1] and [166].

Proof. (i) $r(w)Nr(w)^{-1}e_i = \|w\|^{-i}r(w)e_{i+1} = \|w\|e_{i+1}$, so the relation holds. $\ker N = \Omega e_{n-1}$ is a line. If $V = V' \oplus V''$ as Weil-Deligne representations, $\ker N = \ker N|_{V'} \oplus \ker N|_{V''}$, and a nilpotent operator on a nonzero space has a nonzero kernel; so V' or V'' is 0. (ii) $N^2 = 0$ and $\ker N = \operatorname{im} N$ is a line, $r(W_K)$-stable (Proposition 7.70). Let μ' be the character of W_K on $\ker N$ and μ that on $V/\ker N$. From $Nr(w) = \|w\|^{-1}r(w)N$ applied to $v \notin \ker N$ we get $\mu(w)Nv = \|w\|^{-1}\mu'(w)Nv$, so $\mu' = \|\cdot\|\mu$. Since $\mu'(\Phi) = q^{-1}\mu(\Phi) \neq \mu(\Phi)$, the operator $r(\Phi)$ has two distinct eigenvalues, so it is semisimple, and there is an eigenvector $e_0 \notin \ker N$ with $r(\Phi)e_0 = \mu(\Phi)e_0$. For $\sigma \in I_K$, $r(\sigma)$ has finite order, hence is semisimple, with the eigenvalue $\mu(\sigma) = \mu'(\sigma)$ on $\ker N$ and on $V/\ker N$; so $r(\sigma) = \mu(\sigma)$ is a scalar. Hence $r(w)e_0 = \mu(w)e_0$ for all $w = \Phi^n\sigma$. Put $e_1 = Ne_0$; then $r(w)e_1 = \|w\|Nr(w)e_0 = \|w\|\mu(w)e_1$. In the basis e_0, e_1, $(r,N) = \mathrm{sp}(2) \otimes \mu$; and μ is determined as the character on $V/\ker N$. □

Example 7.74 (the Tate shape)**.** Let $\ell \neq p$, $x \in K^\times$ with $a = v_K(x)$, $\varepsilon\colon G_K \to \{\pm 1\}$ unramified, and let ρ act on $\mathbb{Q}_\ell e_1 \oplus \mathbb{Q}_\ell e_2$ by

$$\rho(g) = \begin{pmatrix} \chi_\ell(g)\varepsilon(g) & \varepsilon(g)\kappa_x(g) \\ 0 & \varepsilon(g) \end{pmatrix},$$

with κ_x read in $\mathbb{Z}_\ell$ through ζ. This is a homomorphism: the upper right entry of $\rho(g)\rho(h)$ is $\varepsilon(gh)(\chi_\ell(g)\kappa_x(h) + \kappa_x(g)) = \varepsilon(gh)\kappa_x(gh)$. (It is the twist by ε of the Kummer representation $\left(\begin{smallmatrix}\chi_\ell & \kappa_x \\ 0 & 1\end{smallmatrix}\right)$ of Chapter 5; the corner of the twist is $\varepsilon\kappa_x$, and the matrix with corner κ_x and diagonal $\chi_\ell\varepsilon, \varepsilon$ is not a homomorphism unless $\varepsilon = 1$.)

(i) On I_K, $\rho(\sigma) = \left(\begin{smallmatrix}1 & a\,t_\zeta(\sigma) \\ 0 & 1\end{smallmatrix}\right) = \exp(t_\zeta(\sigma)N)$ with $N = aE_{12}$ ($Ne_2 = ae_1$, $Ne_1 = 0$), by Theorem 7.58(ii); here $I_1 = I_K$, and $N \neq 0$ iff $a \neq 0$. With $\rho(\mathrm{Frob}) = \left(\begin{smallmatrix}\varepsilon q & c' \\ 0 & \varepsilon\end{smallmatrix}\right)$ one checks $\rho(\mathrm{Frob})N\rho(\mathrm{Frob})^{-1} = qN$: for an upper triangular $g = \left(\begin{smallmatrix}x & y \\ 0 & z\end{smallmatrix}\right)$ one has $gE_{12} = xE_{12}$ and $E_{12}g = zE_{12}$, so $gE_{12}g^{-1} = (x/z)E_{12}$, and here $x/z = \varepsilon q/\varepsilon = q$.

(ii) If $a \neq 0$: r is unramified, $r(\Phi) = \rho(\mathrm{Frob})^{-1}$ has the distinct eigenvalues εq^{-1} (on e_1) and ε (on the quotient), with $\varepsilon = \varepsilon(\mathrm{Frob})$, so $\mathrm{WD}(\rho) \simeq \mathrm{sp}(2) \otimes \mu_\varepsilon$ with μ_ε unramified, $\mu_\varepsilon(\Phi) = \varepsilon(\mathrm{Frob})$ (Proposition 7.73(ii)). Moreover $V^{I_K} = \mathbb{Q}_\ell e_1$, on which Φ acts by εq^{-1} and Frob by εq.

(iii) If $a = 0$: ρ is unramified, $N = 0$, and Frob has the distinct eigenvalues εq, ε.

(iv) On the lattice $\mathbb{Z}_\ell e_1 \oplus \mathbb{Z}_\ell e_2$, I_K acts trivially modulo ℓ^k iff $\ell^k \mid a$ (Theorem 7.58(v)).

Chapters 10 and 11 show that $T_\ell E$, at a prime of multiplicative reduction, has exactly this shape, with $x = q_E$ the Tate parameter and ε trivial (split) or the unramified quadratic character (nonsplit).

In the paper 7.75. In Lemma lem:euler (type I_n) and in the proof of Lemma lem:twist(iii), the paper uses that the local component is an unramified twist of the Steinberg representation. On the Galois side this means $\mathrm{WD}(V_\ell E|_{G_{\mathbb{Q}_q}}) \simeq \mathrm{sp}(2) \otimes \mu$ with μ unramified, which is Example 7.74(ii) for the Tate shape; the passage between the automorphic and the Galois side is Chapter 15. The proof of Lemma lem:tamfactor uses exactly the matrices of Example 7.74, with corner $\varepsilon\kappa$ (the paper notes that $\varepsilon\kappa$, not κ, satisfies the cocycle relation for the twisted matrices), $te_2 = e_2 + n'e_1$ with $n' = n\,t_\zeta(t)$, and $v_\ell(n') = v_\ell(n)$ for a generator t of tame inertia.

7.8 Inertia invariants, local L-factors and conductors

The paper's local terms are built from three invariants of $V = V_\ell E$ and of $A_f = \mathrm{ad}^0 V$ at a bad prime: the inertia invariants (the paper's $\delta_p = \dim V^{I_p}$), the local L-factor, read with the geometric Frobenius, and the conductor exponent. This section defines them, proves that they depend only on the Weil-Deligne representation, and fixes the Frobenius convention for L-factors. The paper uses them in Section 1.1 (the definitions of δ_p, $L_p(A_f, s)$ and L_p^{nv}), in Definition def:terms, Lemma lem:euler and the table of Section 1, in Lemma lem:fpr ($L_p(A_f, 1) = L_p(A_f(1), 0)$), in the paragraph after Lemma lem:dfg21, and in Lemmas lem:twist and lem:IV and Remark rem:types (conductor exponents).

Proposition 7.76 (inertia invariants)**.** *Let $\rho\colon G_K \to \mathrm{GL}(V)$ be continuous, $\ell \neq p$, and $\mathrm{WD}(\rho) = (r, N)$ as in Theorem 7.71. Then*

$$V^{\rho(I_K)} = (\ker N)^{r(I_K)},$$

and $\rho(\Phi) = r(\Phi)$ on this space. So $\dim V^{I_K}$ and the characteristic polynomial of Φ on V^{I_K} depend only on the isomorphism class of $\mathrm{WD}(\rho)$.

Proof. For $\sigma \in I_K$, $\rho(\sigma) = r(\sigma)\exp(t_\zeta(\sigma)N)$. If $Nv = 0$ and $r(\sigma)v = v$ for all σ, then $\rho(\sigma)v = v$. Conversely let v be fixed by $\rho(I_K)$. Take $\sigma_1 \in I_1$ with $t_\zeta(\sigma_1) = \ell^m \neq 0$; then $v = \exp(\ell^m N)v$, and $\exp(\ell^m N) - 1 = \ell^m N U$ with $U = \sum_{k\geq 0}(\ell^m N)^k/(k+1)!$ unipotent and commuting with N, so $NUv = UNv = 0$ and $Nv = 0$. Then $r(\sigma)v = \rho(\sigma)\exp(-t_\zeta(\sigma)N)v = \rho(\sigma)v = v$. Finally $r(\Phi) = \rho(\Phi)$ by definition. An isomorphism of Weil-Deligne representations carries $(\ker N)^{r(I_K)}$ to the corresponding space and intertwines $r(\Phi)$. □

For example, $(\ker N)^{r(I_K)}$ is Ωe_1 for $\mathrm{sp}(2) \otimes \mu$ with μ unramified, and 0 for $\mathrm{sp}(2) \otimes \mu$ with μ ramified ($r(I_K)$ acts on $\ker N = \Omega e_1$ by the nontrivial $\mu|_{I_K}$); for $(r, 0)$ it is $V^{r(I_K)}$. The paper's δ_p is $\dim V^{I_p}$ for $V = V_\ell E$ (Section 1.1).

Definition 7.77 (local L-factors)**.** For ρ as in Proposition 7.76, or a Weil-Deligne representation (r, N), the *local L-factor* is

$$L(V, s) = \det\bigl(1 - \Phi\, q^{-s} \mid V^{I_K}\bigr)^{-1} = \det\bigl(1 - r(\Phi)\, q^{-s} \mid (\ker N)^{r(I_K)}\bigr)^{-1},$$

with $\Phi = \mathrm{Frob}^{-1}$ the geometric Frobenius. For $K = \mathbb{Q}_p$ and a representation M of $G_{\mathbb{Q}}$ we write $L_p(M, s)$; this is the paper's $L_p(\cdot, s)$ of Section 1.1 (Appendix B, convention B-C2(d)).

Proposition 7.78. *(i) $L(V, s)$ is well defined (any two geometric Frobenius lifts agree on V^{I_K}) and depends only on the isomorphism class of $\mathrm{WD}(V)$.*

(ii) $L(V \oplus V', s) = L(V, s)L(V', s)$.

(iii) For μ unramified with $\mu(\Phi) = \lambda$, $L(\mu, s) = (1 - \lambda q^{-s})^{-1}$. In particular $L(\mathbb{Q}_\ell(1), s) = (1 - q^{-1-s})^{-1}$, $L(V(1), s) = L(V, s+1)$ and $L(V \otimes \|\cdot\|^k, s) = L(V, s+k)$.

(iv) With the arithmetic Frob *in place of Φ one would get $(1-q^{1-s})^{-1}$ for $\mathbb{Q}_\ell(1)$ and $L(V(1), s) = L(V, s-1)$.*

(v) $L(\mathrm{sp}(2)\otimes\mu,s)=(1-\mu(\Phi)q^{-1-s})^{-1}$ *for* μ *unramified, and* $=1$ *for* μ *ramified. If* $E/\mathbb{Q}$ *has good reduction at* $p\neq\ell$ *and* α,β *are the roots of* X^2-a_pX+p*, the arithmetic Frobenius on* $V_\ell E$ *has eigenvalues* α,β *(Chapter 9), the geometric one* α^{-1},β^{-1}*, and*

$$L_p(V_\ell E,s)=(1-a_pp^{-1-s}+p^{-1-2s})^{-1}=L_p(E,s+1),$$
$$L_p(V_\ell E^\vee,s)=(1-a_pp^{-s}+p^{1-2s})^{-1}=L_p(E,s).$$

Proof. (i) Two lifts differ by an element of I_K, which acts trivially on V^{I_K}; V^{I_K} is Φ-stable because I_K is normal. The second expression and Proposition 7.76 give the independence. (ii) Invariants and determinants are additive. (iii) I_K acts trivially on $\mathbb{Q}_\ell(1)$ and Φ by $\chi_\ell(\Phi)=q^{-1}$; $V(1)^{I_K}=V^{I_K}(1)$, on which Φ acts by q^{-1} times its action on V^{I_K}, so $\det(1-\Phi q^{-s}\mid V(1)^{I_K})=\det(1-\Phi q^{-s-1}\mid V^{I_K})$. The same holds for $\|\cdot\|^k$. (iv) Frob acts on $\mathbb{Q}_\ell(1)$ by q. (v) The first statement is Proposition 7.76 and the example after it, Φ acting on e_1 by $\mu(\Phi)\|\Phi\|=\mu(\Phi)q^{-1}$. For E: $\det(1-\Phi X\mid V_\ell E)=(1-X/\alpha)(1-X/\beta)=1-a_pX/p+X^2/p$; with $X=p^{-s}$ this is $1-a_pp^{-1-s}+p^{-1-2s}$, which is $1-a_pp^{-(s+1)}+p^{1-2(s+1)}$. On $V^\vee$ the geometric Frobenius has the inverse eigenvalues α,β, giving $1-a_pX+pX^2$. □

Warning 7.79 (the paper's L-factors are geometric). The paper's $L_p(A_f,s)$, the table of Section 1, Lemma lem:euler, Lemma lem:fpr ($L_p(A_f,1)^{-1}=L_p(A_f(1),0)^{-1}$), the values of PARI's `lfunsympow` and the conventions of DFG04 [49, Section 1.7.2] all use the geometric Frobenius: by Proposition 7.78(iii), (iv) the identity $L_p(M(1),s)=L_p(M,s+1)$ of Lemma lem:fpr holds for Φ and fails for Frob, and at a multiplicative prime the factor $1-q^{-1-s}$ of the table requires Φ (Proposition 7.88(iii)). On ad^0V at a good prime the eigenvalues $\alpha/\beta,1,\beta/\alpha$ are stable under inversion, so there the choice is invisible.

In the paper 7.80. Section 1.1 defines $L_p(A_f,s)=\det(1-\mathrm{Frob}_p^{-1}p^{-s}\mid A_f^{I_p})^{-1}$: this is Definition 7.77 for $M=A_f$, the geometric Frobenius at p being Frob_p^{-1}. The naive factor $L_p^{\mathrm{nv}}(A_f,s)$ is $L_p(A_f,s)$ when $\delta_p=\dim V^{I_p}>0$ and 1 when $\delta_p=0$. The paragraph after Lemma lem:dfg21 writes "$\det(1-\mathrm{Frob}_p^{-1}\mid(V^D)^{I_p})=L_p(A_f,1)^{-1}\neq0$" with $V^D=A_f(1)$: the left side is $L_p(A_f(1),0)^{-1}$, which equals $L_p(A_f,1)^{-1}$ by Proposition 7.78(iii).

7.8.1 Swan and Artin conductors

Definition 7.81 (Swan and Artin conductors)**.** Let V be a finite-dimensional representation over a field Ω of G_K, W_K or I_K, on which I_K acts through a finite quotient. Choose a finite Galois L/K such that $I_K\cap G_L$ acts trivially (possible because the kernel is open in I_K), so that I_K acts through its image $G_0=I(L/K)$ in $\mathrm{Gal}(L/K)$ (Theorem 7.45(i)); let $G_i=G_i(L/K)$ and $g_i=\#G_i$. The *Swan conductor* and the *Artin conductor* (exponent) are

$$\mathrm{sw}(V)=\sum_{i\geq1}\frac{g_i}{g_0}\dim(V/V^{G_i}),\qquad a(V)=\sum_{i\geq0}\frac{g_i}{g_0}\dim(V/V^{G_i})=\dim V-\dim V^{I_K}+\mathrm{sw}(V).$$

For a continuous ℓ-adic ρ ($\ell\neq p$), P_K acts through a finite quotient (Proposition 7.53), and $\mathrm{sw}(\rho)$ is defined by the same sum, which involves only the G_i with $i\geq1$, the images of P_K.

Theorem 7.82 (properties of the conductors)**.** *(i) (Stated.)* $\mathrm{sw}(V)$ *and* $a(V)$ *do not depend on the choice of* L *(by Herbrand's theorem), and in upper numbering*

$$\mathrm{sw}(V)=\int_0^\infty\dim(V/V^{G_K^u})\,du.$$

(ii) (Stated; Artin.) $\mathrm{sw}(V)$ *and* $a(V)$ *are nonnegative integers.*

(iii) $\mathrm{sw}(V) = 0$ *iff* P_K *acts trivially on* V*;* $\mathrm{sw}(V)$ *depends only on* $V|_{P_K}$*; both are additive in direct sums, unchanged by twisting by an unramified character and by restriction to* $G_{K'}$ *for* K'/K *finite unramified; and if* V *is tamely ramified,* $a(V) = \dim V - \dim V^{I_K}$*.*

(iv) For a character χ*:* $a(\chi) = 0$ *if* χ *is unramified,* $a(\chi) = 1$ *if it is tamely ramified, and* $a(\chi) = 1 + (\text{the largest } i \text{ with } \chi(G_i) \neq 1)$ *for the quadratic characters of Example 7.43. Hence* $a(\chi_{-3}|_{G_{\mathbb{Q}_3}}) = 1$*,* $a(\chi_{q^*}|_{G_{\mathbb{Q}_q}}) = 1$ *for* q *odd,* $a(\chi_{-4}|_{G_{\mathbb{Q}_2}}) = 2$ *and* $a(\chi_{\pm 8}|_{G_{\mathbb{Q}_2}}) = 3$*, in agreement with Theorem 7.62(iii) and with the conductors* 3*,* q*,* 4*,* 8*. (Stated: for a general wildly ramified character,* $a(\chi) = 1 + c$ *with* c *the largest upper jump.)*

(v) The same definitions apply verbatim to representations over $\mathbb{F}_\ell$*, where the image of inertia is finite; this gives the local factor at* q *of the Serre conductor of* $\bar{\rho}_{E,\ell}$ *(Chapter 11).*

Proof of (iii), (iv); references for (i), (ii). (iii) If P_K acts trivially, so does each G_i, $i \geq 1$, and all terms vanish. If $\mathrm{sw}(V) = 0$, then either $G_1 = 1$, or the term $i = 1$ (with $g_1/g_0 > 0$) vanishes and G_1 acts trivially; in both cases P_K, which maps onto G_1, acts trivially. The sum for $i \geq 1$ involves only $V|_{G_1}$, the image of $V|_{P_K}$. Additivity holds because $(V \oplus V')^{G_i} = V^{G_i} \oplus V'^{G_i}$. An unramified character is trivial on I_K, so it does not change any V^{G_i}. If K'/K is unramified and $L' = LK'$, the inertia group of L'/K fixes K', so the ramification groups of L'/K', which are $G_i(L'/K) \cap \mathrm{Gal}(L'/K')$ (Proposition 7.42(i)), equal $G_i(L'/K)$ for $i \geq 0$; by (i) one may compute both conductors with L'. If V is tame, P_K acts trivially and $\mathrm{sw} = 0$. (iv) For a character, $\dim V/V^{G_i}$ is 1 if $\chi(G_i) \neq 1$ and 0 otherwise. If χ is tamely ramified, $\chi(G_0) \neq 1 = \chi(G_1)$ and $a = 1$. For the quadratic characters of Example 7.43 the field L is the quadratic extension itself, $g_i/g_0 = 1$ while $G_i = G$; so $a = 1 + 1 = 2$ for the jump 1 ($\mathbb{Q}_2(i)$, $\mathbb{Q}_2(\sqrt{3})$) and $a = 1 + 2 = 3$ for the jump 2 ($\mathbb{Q}_2(\sqrt{\pm 2})$, $\mathbb{Q}_2(\sqrt{\pm 10})$). The values for the global characters follow from Proposition 7.61(ii), (iii). (i) and (ii) are Serre [174, Chapter IV, Section 3, and Chapter VI, Section 2]; the integrality is Artin's theorem, proved there through the Artin character (see also [173, Chapter 19]). (v) is a definition. □

Definition 7.83 (conductor of a Weil-Deligne representation)**.** The conductor exponent of a Weil-Deligne representation (r, N, V) is

$$a(r, N) = a(r) + \dim V^{r(I_K)} - \dim(\ker N)^{r(I_K)} = \dim V - \dim(\ker N)^{r(I_K)} + \mathrm{sw}(r),$$

and for a continuous ℓ-adic ρ, $a(\rho) = a(\mathrm{WD}(\rho))$.

Proposition 7.84. *(i)* $a(\rho) = \dim V - \dim V^{\rho(I_K)} + \mathrm{sw}(\rho)$*, where* $\mathrm{sw}(\rho) = \mathrm{sw}(\rho|_{P_K})$*.*

(ii) a *is additive in direct sums, unchanged by unramified twists and by unramified base change,* $a(\rho) = 0$ *iff* ρ *is unramified, and* $a(\rho) = \dim V - \dim V^{I_K}$ *if* ρ *is tamely ramified.*

(iii) If V *is unramified and* χ *is a character,* $a(V \otimes \chi) = \dim V \cdot a(\chi)$*. If* χ *is ramified and* μ *unramified,* $a(\mathrm{sp}(2) \otimes \mu) = 1$ *and* $a(\mathrm{sp}(2) \otimes \mu\chi) = 2a(\chi)$*.*

(iv) For an elliptic curve $E/\mathbb{Q}$ *and* $\ell \neq p$*, Chapter 10 defines the exponent of* p *in the conductor of* E *to be* $a(V_\ell E|_{G_{\mathbb{Q}_p}})$*; it does not depend on* ℓ*. (Stated.) Ogg's formula (Saito in general) gives it as* $v_p(\Delta_{\min}) + 1 - m$*, where* m *is the number of irreducible components over* $\overline{\mathbb{F}}_p$ *of the special fibre of the minimal regular model of* E *over* $\mathbb{Z}_p$ *(Chapter 10).*

Proof. (i) By Proposition 7.76, $(\ker N)^{r(I_K)} = V^{\rho(I_K)}$; and $r = \rho$ on P_K, because t_ζ vanishes on P_K; so $\mathrm{sw}(r) = \mathrm{sw}(\rho)$. (ii) follows from (i), Theorem 7.82(iii) and Proposition 7.38; $a(\rho) = 0$ forces $V^{I_K} = V$. (iii) I_K acts on $V \otimes \chi$ by the scalars $\chi(\sigma)$, so $(V \otimes \chi)^{G_i}$ is $V \otimes \chi$ or 0 according as $\chi(G_i) = 1$ or not, and each term of the sum is $\dim V$ times that for χ. For $\mathrm{sp}(2) \otimes \mu$, r is unramified and $\dim(\ker N)^{r(I_K)} = 1$, so $a = 2 - 1 + 0 = 1$. For $\mathrm{sp}(2) \otimes \mu\chi$, $r = (\mu\chi \oplus \|\cdot\|\mu\chi)$ has $a(r) = 2a(\chi)$ by the previous case, and $(\ker N)^{r(I_K)} = V^{r(I_K)} = 0$, so $a = 2a(\chi)$. (iv) The first sentence is a definition. We do not prove the independence of ℓ or Ogg's formula; see [179, Section 2], Ogg [145] and Chapter 10, where Saito's general case is cited. □

Theorem 7.85 (epsilon factors)**.** *(Langlands, Deligne.) Fix a nontrivial additive character ψ of K and a Haar measure dx on K. There is a unique way to attach to each representation r of W_K over $\mathbb{C}$ with $r(I_K)$ finite a constant $\epsilon(r, \psi, dx) \in \mathbb{C}^\times$ that is multiplicative in short exact sequences, inductive in degree 0, and equal to Tate's local constant for characters. For a Weil-Deligne representation one puts*

$$\epsilon(r, N, \psi, dx) = \epsilon(r, \psi, dx)\, \det\!\big(-r(\Phi) \mid V^{r(I_K)}/(\ker N)^{r(I_K)}\big).$$

We do not prove this; see Deligne [41, Sections 4, 5 and 8] and Tate [194, Sections 3 and 4] (Deligne's normalisation of the Artin map is the geometric one, Warning 7.63). The paper does not use epsilon factors; Chapters 15 and 19 recall this statement for root numbers and functional equations.

7.9 The local shapes and their adjoints

This section computes, for each shape of local representation that the paper meets, the inertia invariants, the conductor exponent and the L-factor of V and of its trace-zero adjoint $A = \mathrm{ad}^0 V$. It is the Galois-theoretic content of Lemma lem:euler, of the table of Section 1, of Proposition prop:shapes and of the conductor statements in Lemmas lem:IV and lem:twist. The linear algebra of the inertia actions (unipotent elements, commutants, the table of cyclic inertia shapes) is Chapter 4; the dictionary between shapes and Kodaira types is proved in Chapters 10 and 11 and only quoted here.

Standing hypotheses: $K = \mathbb{Q}_q$, $\ell \neq q$, V a two-dimensional representation of $G_{\mathbb{Q}_q}$ over a finite extension Ω of $\mathbb{Q}_\ell$ with $\det V|_{I_q} = 1$ (true for $V_\ell E$, whose determinant χ_ℓ is unramified at q), $A = \mathrm{ad}^0 V$ with $g \cdot x = \rho(g) x \rho(g)^{-1}$, and Φ the geometric Frobenius. In the basis e_1, e_2 of Example 7.74, $e = e_1 \otimes e_2^\vee$, $h = e_1 \otimes e_1^\vee - e_2 \otimes e_2^\vee$, $f = e_2 \otimes e_1^\vee$ is the paper's basis of $\mathrm{ad}^0 T$ (here e is a vector, not a ramification index).

Proposition 7.86 (unramified V)**.** *If V is unramified with arithmetic Frobenius eigenvalues α, β, then $\mathrm{WD}(V) = (r, 0)$, $a(V) = 0$, $L(V, s)^{-1} = (1 - \alpha^{-1}q^{-s})(1 - \beta^{-1}q^{-s})$, and A is unramified with eigenvalues $\alpha/\beta, 1, \beta/\alpha$ for both* Frob *and Φ. Hence*

$$L(A, s)^{-1} = \Big(1 - \frac{\alpha}{\beta}q^{-s}\Big)(1 - q^{-s})\Big(1 - \frac{\beta}{\alpha}q^{-s}\Big), \qquad L(A, 1)^{-1} = \frac{q-1}{q} \cdot \frac{(q+1)^2 - a^2}{q^2},$$

the last formula when $\alpha + \beta = a$ and $\alpha\beta = q$.

Proof. $N = 0$ since $\rho(I_q) = 1$ is finite, and $a = 0$ by Proposition 7.84(ii). The eigenvalues of Φ on V are α^{-1}, β^{-1}. If Frob has eigenvectors v_1, v_2 (over an extension of Ω, or after triangularising), it acts on $v_i \otimes v_j^\vee$ by α_i/α_j; the trace-zero part has eigenvalues α/β, 1, β/α, a set stable under

inversion. For $s=1$, $(1-\frac{\alpha}{\beta q})(1-\frac{\beta}{\alpha q}) = 1-\frac{\alpha^2+\beta^2}{\alpha\beta q}+\frac{1}{q^2} = 1-\frac{a^2-2q}{q^2}+\frac{1}{q^2} = \frac{(q+1)^2-a^2}{q^2}$ (Chapter 2), using $\alpha^2+\beta^2 = (\alpha+\beta)^2-2\alpha\beta = a^2-2q$; the middle factor contributes $1-q^{-1} = \frac{q-1}{q}$. □

For example, `11a1` has good reduction at 2 with $a_2=-2$ (PARI, `ellap`), so $L_2(A,1)^{-1} = \frac{1}{2}\cdot\frac{9-4}{4} = \frac{5}{8}$. Note that $(q+1)^2-a^2 = (q+1-a)(q+1+a)$, and $q+1-a$ is the number of points of the reduced curve over $\mathbb{F}_q$ (Chapter 9); here $\#\tilde{E}(\mathbb{F}_2)=5$, and the factor 5 in $\frac{5}{8}$ is that count.

Proposition 7.87 (finite cyclic tame image of inertia)**.** *Suppose $\rho(I_q)$ is cyclic of order $m \in \{2,3,4,6\}$ with $q \nmid m$, generated by g. Then $N=0$, the ramification is tame, and:*

(i) If $m=2$, then $g=-1$, $V^{I_q}=0$, $a(V)=2$ and $L(V,s)=1$. For q odd and any ramified quadratic character χ of $G_{\mathbb{Q}_q}$, $V\otimes\chi$ is unramified, and $A=\mathrm{ad}^0(V\otimes\chi)$ is unramified, with $L(A,s)$ as in Proposition 7.86 for $V\otimes\chi$.

(ii) If $m\in\{3,4,6\}$, g has the eigenvalues ζ,ζ^{-1} with ζ a primitive m-th root of unity; $V^{I_q}=0$, $a(V)=2$ and $L(V,s)=1$. Put $m'=3$, $\chi=\chi_{-3}$ if $m\in\{3,6\}$, and $m'=4$, $\chi=\chi_{-4}$ if $m=4$. Then $\rho(\mathrm{Frob})g\rho(\mathrm{Frob})^{-1}=g^{\chi(q)}$. If $\chi(q)=1$, $V\otimes\Omega(\zeta)$ is a sum of two characters of $G_{\mathbb{Q}_q}$ restricting to $\zeta^{\pm1}$ on g; if $\chi(q)=-1$, $\rho(\mathrm{Frob})$ exchanges the two eigenlines of g, and $V\otimes\Omega(\zeta)$ is induced from a character of G_{K_2}, K_2 the unramified quadratic extension of $\mathbb{Q}_q$.

(iii) In case (ii), A^{I_q} is the line spanned by $2g-\operatorname{tr} g$ (which is $\pm(2\sigma+1)$, of square -3, for $m\in\{3,6\}$ with σ the element of order 3 in $\langle g\rangle$, and g itself for $m=4$), and both Frob *and* Φ *act on it by $\chi(q)\in\{\pm1\}$. Hence*

$$L(A,s)^{-1} = 1-\chi(q)\,q^{-s}, \qquad a(A)=2.$$

Proof. $\rho(I_q)$ is finite, so $N=0$ (Theorem 7.68), and of order prime to q, so $\rho(P_q)=1$ (Corollary 7.52). Since $\det g=1$, the eigenvalues of g (semisimple, of finite order in characteristic 0) are λ,λ^{-1} with λ of order m. (i) For $m=2$, $\lambda=\lambda^{-1}$ forces $\lambda=-1$ and $g=-1$. In all cases 1 is not an eigenvalue, so $V^{I_q}=0$, $L(V,s)=1$ and $a(V)=2-0=2$ (tame). If q is odd and χ ramified quadratic, then $\chi|_{I_q}=\theta_2$ (Proposition 7.60(ii)), and $\rho|_{I_q}$ is a character of I_q of order 2 times the identity, so it is $\theta_2\cdot 1$; hence $(V\otimes\chi)|_{I_q}=\theta_2^2=1$. Twisting by a character does not change ad^0. (ii) By Corollary 7.52, $\rho(\mathrm{Frob})g\rho(\mathrm{Frob})^{-1}=g^q$. For $m\in\{3,4\}$, $q\equiv\chi(q) \pmod{m'}$ and $g^q=g^{\chi(q)}$, as g has order $m=m'$. For $m=6$, q is prime to 6, so $q\equiv\pm1 \pmod 6$ and again $g^q=g^{\pm1}$ with the sign $\chi_{-3}(q)$. If $\rho(\mathrm{Frob})$ commutes with g, it preserves the two eigenlines of g in $V\otimes\Omega(\zeta)$, and so does $\rho(I_q)=\langle g\rangle$; by Corollary 7.46 these lines are stable under $G_{\mathbb{Q}_q}$. If $\rho(\mathrm{Frob})g\rho(\mathrm{Frob})^{-1}=g^{-1}$, $\rho(\mathrm{Frob})$ maps the ζ-eigenline D to the ζ^{-1}-eigenline; D is stable under the index-two subgroup $G_{K_2}=I_q\rtimes\overline{\langle\mathrm{Frob}^2\rangle}$, and $V\otimes\Omega(\zeta)=D\oplus\rho(\mathrm{Frob})D$ is induced from the character of G_{K_2} on D. (iii) The commutant of g in $\mathrm{End}\,V$ is $\Omega+\Omega g$, since g has distinct eigenvalues (Chapter 4), so its trace-zero part is spanned by $2g-\mathrm{tr}(g)$; and A^{I_q} is that trace-zero commutant. By Cayley-Hamilton, $g^{-1}=\mathrm{tr}(g)-g$, so $2g^{-1}-\operatorname{tr} g=-(2g-\operatorname{tr} g)$; therefore Frob, which conjugates g to $g^{\chi(q)}$, acts on the line by $\chi(q)$, and so does $\Phi=\mathrm{Frob}^{-1}$. For $m=3$, $\operatorname{tr}\sigma=-1$ and $(2\sigma+1)^2=4(\sigma^2+\sigma)+1=-3$; for $m=6$, $g=-\sigma$; for $m=4$, $\operatorname{tr} g=0$. Finally A is tame (its inertia image is a quotient of $\langle g\rangle$), so $a(A)=3-1=2$. □

Proposition 7.88 (Steinberg and its twists)**.** *Let μ be an unramified and χ a ramified quadratic character of $G_{\mathbb{Q}_q}$.*

(i) $V = \mathrm{sp}(2) \otimes \mu$*:* $V^{I_q} = \ker N$ *is a line on which* Φ *acts by* $\mu(\Phi)q^{-1}$ *(and* Frob *by* $\mu(\mathrm{Frob})q$*);* $a(V) = 1$*;* $L(V,s) = (1 - \mu(\Phi)q^{-1-s})^{-1}$*.*

(ii) $V = \mathrm{sp}(2) \otimes \mu\chi$*:* $V^{I_q} = 0$*,* $L(V,s) = 1$ *and* $a(V) = 2a(\chi)$*, which is* 2 *for* q *odd and* 4 *or* 6 *for* $q = 2$*.*

(iii) For $V = \mathrm{sp}(2) \otimes \mu$ *and* $V = \mathrm{sp}(2) \otimes \mu\chi$*,* $\mathrm{ad}^0 V = \mathrm{ad}^0 \mathrm{sp}(2) \simeq \mathrm{sp}(3) \otimes \|\cdot\|^{-1}$*. In the basis* E_{01}*,* $h = E_{00} - E_{11}$*,* $E_{10} = N$ *(with* $E_{ij} = e_i \otimes e_j^\vee$ *in the basis of Definition 7.72),* Φ *acts by* $q, 1, q^{-1}$*, and* $[N, E_{01}] = -h$*,* $[N,h] = 2N$*,* $[N,N] = 0$*. So* $A^{I_q} = \ker[N,\cdot\,] = \Omega N$*,* Φ *acts on it by* q^{-1} *(*Frob *by* q*),* $a(A) = 2$*, and*

$$L(\mathrm{ad}^0 V, s) = (1 - q^{-1-s})^{-1}.$$

With the arithmetic Frobenius one would get $(1 - q^{1-s})^{-1}$*.*

(iv) The line ΩN *is the line of* $e = e_1 \otimes e_2^\vee$ *in the basis of Example 7.74, the line* $\mathbb{Z}_\ell e$ *of the proof of Lemma lem:tamfactor.*

Proof. (i) and (ii) are Proposition 7.76, Proposition 7.78(v) and Proposition 7.84(iii), with $a(\chi) = 1$ for q odd and $a(\chi) \in \{2,3\}$ for $q = 2$ (Theorem 7.82(iv)). (iii) Twisting by a character does not change ad^0. $r(\Phi)$ acts on e_0, e_1 by $1, q^{-1}$, hence on E_{ij} by the ratio of the eigenvalues of e_i and e_j: q on E_{01}, 1 on h, q^{-1} on E_{10}. The brackets: $E_{10}E_{01} - E_{01}E_{10} = E_{11} - E_{00} = -h$; $E_{10}h - hE_{10} = E_{10} + E_{10} = 2E_{10}$. So $f_0 = E_{01}$, $f_1 = -h$, $f_2 = -2E_{10}$ satisfy $N_{\mathrm{ad}^0} f_i = f_{i+1}$, with Φ-eigenvalues $q^{1-i} = \|\Phi\|^{i-1}$: this is $\mathrm{sp}(3) \otimes \|\cdot\|^{-1}$. In characteristic 0, $\ker N_{\mathrm{ad}^0} = \Omega E_{10} = \Omega N$, and $r(I_q)$ acts trivially on ad^0 (it acts on V by scalars), so $A^{I_q} = \Omega N$ (Proposition 7.76), with Φ-eigenvalue q^{-1}. $a(A) = 3 - 1 + 0 = 2$. (iv) In Example 7.74, $N = aE_{12}$ maps e_2 to e_1, so N is a multiple of $e_1 \otimes e_2^\vee$. □

Theorem 7.89 (the shapes at a tame prime)**.** *Under the standing hypotheses, suppose that* $q \geq 5$*. (Columns* 1 *to* 7*, which do not involve Kodaira types, hold more generally, with the same proofs: rows* 1 *and* 3 *for every* q*, rows* 2 *and* 4 *for every odd* q*, and rows* 5 *and* 6 *whenever* $q \nmid \#\rho(I_q)$*. The Kodaira column is asserted only for* $q \geq 5$*.) The following table lists, for each shape of* $\mathrm{WD}(V)$*, the image of inertia,* $\dim V^{I_q}$*,* $a(V)$*,* $L(V,s)^{-1}$*,* $\dim A^{I_q}$ *and* $L(A,s)^{-1}$ *(*Φ *geometric); the last column, the Kodaira types of an elliptic curve with* $V = V_\ell E$*, is quoted from Chapters 10 and 11.*

$\mathrm{WD}(V)$	$\rho(I_q)$	δ_q	$a(V)$	$L(V,s)^{-1}$	$\dim A^{I_q}$	$L(A,s)^{-1}$	*types*
unramified	1	2	0	$(1 - \frac{X}{\alpha})(1 - \frac{X}{\beta})$	3	$(1 - \frac{\alpha}{\beta}X)(1 - X)(1 - \frac{\beta}{\alpha}X)$	I_0
unram. $\otimes\, \chi$	$\{\pm 1\}$	0	2	1	3	*as in row* 1	I_0^*
$\mathrm{sp}(2) \otimes \mu$	*unipotent*	1	1	$1 - \mu(\Phi)q^{-1}X$	1	$1 - q^{-1}X$	I_n
$\mathrm{sp}(2) \otimes \mu\chi$	$\pm$*unipotent*	0	2	1	1	$1 - q^{-1}X$	I_n^*
order 3 *or* 6	$\langle\sigma\rangle$, $\langle -\sigma\rangle$	0	2	1	1	$1 - \chi_{-3}(q)X$	$\mathrm{IV}, \mathrm{IV}^*$; $\mathrm{II}, \mathrm{II}^*$
order 4	$\langle\tau\rangle$	0	2	1	1	$1 - \chi_{-4}(q)X$	$\mathrm{III}, \mathrm{III}^*$

Here $X = q^{-s}$*,* $\delta_q = \dim V^{I_q}$*,* α, β *are the arithmetic Frobenius eigenvalues of the unramified representation (in the second row, of* $V \otimes \chi$*),* μ *is unramified,* χ *is a ramified quadratic character,* $N = 0$ *in the last two rows, and* $n \geq 1$*. So* δ_q *is* $2, 0, 1, 0, 0, 0$ *down the rows; the naive factor is* $L(A,s)$ *when* $\delta_q > 0$ *and* 1 *when* $\delta_q = 0$*; and the factor that the naive L-function omits is* $L(A,s)^{-1}$ *in rows* 2*,* 4*,* 5*,* 6 *and nothing in rows* 1*,* 3*.*

Proof. Every column but the last is Propositions 7.86 to 7.88. That these are all the shapes with $q \nmid \#\rho(I_q)$ when $\rho(I_q)$ is finite of order in $\{1,2,3,4,6\}$ follows from Proposition 7.73(ii) when $N \neq 0$ (and $\det V|_{I_q} = 1$ forces μ^2 to be trivial on I_q, so μ is unramified or an unramified twist of a ramified quadratic character, Corollary 7.46), and from Chapter 4 when $N = 0$. The orders $1,2,3,4,6$ and the Kodaira column are Chapters 10 and 11 (Serre and Tate [179], Kraus [107]); we do not prove them here. □

In the paper 7.90. Lemma lem:euler and the table of Section 1 are the last column of Theorem 7.89 read through the Kodaira types: $L_q(A_f,s)^{-1}$ is $1-q^{-1-s}$ for I_n and I_n^*, $1-\chi_{-3}(q)q^{-s}$ for $\mathrm{II},\mathrm{II}^*,\mathrm{IV},\mathrm{IV}^*$, $1-\chi_{-4}(q)q^{-s}$ for $\mathrm{III},\mathrm{III}^*$ and the good factor of the twist for I_0^*; $e_\ell(E,q) = v_\ell(L_q(A_f,1)^{-1})$ in the rows with $\delta_q = 0$ gives $v_\ell(q^2-1)$, $v_\ell(q-\chi_{-3}(q))$, $v_\ell(q-\chi_{-4}(q))$ and $v_\ell(q-1)+v_\ell((q+1)^2-a_q(E')^2)$, and $e_\ell = 0$ in the rows with $\delta_q > 0$. "Frobenius centralises σ if $q \equiv 1 \pmod 3$ and inverts it if $q \equiv 2$, for either choice of Frobenius" is Proposition 7.87(ii), (iii). "$(\mathrm{ad}^0 V)^{I_q}$ is a line on which the geometric Frobenius has eigenvalue q^{-1}" (type I_n) is Proposition 7.88(iii). Proposition prop:shapes(i) to (iii) is the same computation organised by $P_q(X) = L_q(A_f, s-1)^{-1}$, $X = q^{-s}$: $1-X$ for the Steinberg rows, $(1-qX)(1-(a^2-2q)X+q^2X^2)$ for row 2, $1-cqX$ with $c = \chi(q)$ for rows 5 and 6. In Lemma lem:twist(iii), the fact that the twist of an unramified twist of the Steinberg representation by a ramified quadratic character has conductor exponent 2 (q odd) is Proposition 7.88(ii). In Lemma lem:twist(ii), "the conductor exponents are the tame ones, $\dim V - \dim V^{I_q}$" holds for the exchanges listed there because twisting a tame representation by the tame χ_{q^*} keeps it tame (Proposition 7.61(v)); at $q = 3$ a general additive curve can be wild (Remark 7.54). In Lemma lem:IV, "the conductor exponent of E is $\dim V - \dim V^{I_q} = 2$, there being no wild part" is row 5 with Proposition 7.84(ii), and "The Serre conductor exponent of $\bar\rho_{E,3}$ at q is $\dim E[3] - \dim E[3]^{I_q} = 1$" is Theorem 7.82(v) for the tame mod 3 representation.

Proposition 7.91 (the primes 2 and 3)**.** *Keep the standing hypotheses, with $q \in \{2,3\}$.*

(i) If $q = 3$ and $\rho(I_3)$ is finite of order divisible by 3, then ρ is wildly ramified and $a(V) \geq 3$. If moreover $\rho(I_3)$ is cyclic of order 3 or 6, A^{I_3} is still the line spanned by $2\sigma+1$, and Frob *still acts on it by $+1$ or -1; but the sign is no longer determined by q, since the tame relation is not available on wild inertia.*

(ii) If $q = 2$ and $\rho(I_2)$ is cyclic of order 3, then Proposition 7.87 applies: $a(V) = 2$, $L(A,s)^{-1} = 1-\chi_{-3}(2)2^{-s} = 1+2^{-s}$, and $L(A,1)^{-1} = \frac{3}{2}$.

(iii) If $\rho(I_q)$ is finite and not abelian, then V is an absolutely irreducible representation of $\rho(I_q)$, $A^{I_q} = 0$ and $L(A,s) = 1$.

(iv) For $q = 2$, $a(\mathrm{sp}(2) \otimes \mu\chi)$ is 4 or 6 according as χ has ramification jump 1 or 2.

Proof. (i) I_3/P_3 has no quotient of order 3 (Theorem 7.47(ii)), so an element of order 3 in $\rho(I_3)$ comes from P_3 (Proposition 7.53(ii)), and $\mathrm{sw}(V) \geq \frac{g_1}{g_0}\dim(V/V^{G_1}) > 0$. An element of order 3 and determinant 1 has the eigenvalues $\zeta_3^{\pm 1}$ and fixes no vector, so $V^{I_3} = 0$; as sw is an integer (Theorem 7.82(ii)), $a(V) = 2+\mathrm{sw}(V) \geq 3$. The computation of the commutant in Proposition 7.87(iii) uses only the cyclicity. Frob normalises $\rho(I_3)$, hence its unique subgroup $\langle\sigma\rangle$ of order 3, so $\rho(\mathrm{Frob})\sigma\rho(\mathrm{Frob})^{-1} = \sigma^{\pm 1}$; as $2\sigma^{-1}+1 = 2\sigma^2+1 = -(2\sigma+1)$ (from $\sigma^2+\sigma+1=0$), Frob acts on the line by ± 1. In the tame case the sign was read off from $g \mapsto g^q$, which used the tame relation; that is not available on wild inertia. (ii) $2 \nmid 3$, so the image is tame; $\chi_{-3}(2) = -1$.

(iii) A two-dimensional faithful representation of a finite non-abelian group in characteristic 0 that fixed a line over $\overline{\Omega}$ would be triangular, hence (being semisimple) diagonal and abelian; so it is absolutely irreducible, its commutant is the scalars (Schur, Chapter 4), and the trace-zero commutant is 0. (iv) is Proposition 7.84(iii) with Theorem 7.82(iv). □

Remark 7.92 (what the paper takes from this at 2 and 3). (a) For a curve of type IV or IV* at 2, the image of inertia on $T_\ell E$ is cyclic of order exactly 3; this is a theorem proved in Chapter 11 from $E[3]^{I_2} \simeq \Phi_2^{\mathrm{geom}}[3]$ and in Chapter 10 from the conductor exponent. With Proposition 7.91(ii) and $L(\mathrm{Sym}^2 f, s) = L(A_f, s-1)$ (Chapter 19), $P_2(X) = 1 + 2X$ and $e_3(E,2) = v_3(3/2) = 1$, as Lemma lem:IV and Remark rem:wild state.

(b) For type II or II* at 2 the Kodaira type does not determine the image of inertia. When the image is non-abelian (Q_8 or $\mathrm{SL}_2(\mathbb{F}_3)$, acting absolutely irreducibly), $P_2 = 1$ by Proposition 7.91(iii); but `336f1` has type II at 2 and $P_2 = 1 + 2X$, and `123211` has type II* at 2 and a cubic P_2. Remark rem:wild says this.

(c) At $q = 2$ a curve of type I_n^* may have potentially good reduction, so the Kodaira type does not determine the Weil-Deligne shape (Definition def:terms: $t_\ell = 0$ then); and in the potentially multiplicative case the conductor exponent is 4 or 6 by Proposition 7.91(iv).

(d) At $q = 3$ the image of inertia for types IV, IV* has order divisible by 3 (Chapters 10 and 11), so by (i) these types are wild; the paper says "At $q = 3$ the types IV, IV* are wildly ramified, and the lemma does not apply." This is why Lemma lem:IV excludes $q = 3$ and Lemma lem:euler assumes $q \geq 5$ for the potentially good rows.

7.10 Exercises

Exercise 7.93. Find the first six 5-adic digits of $1/3$ and of $-1/3$, and check, carry by carry, that their sum is 0. Which rational number has the 7-adic expansion $1 + 2\cdot 7 + 1\cdot 7^2 + 2\cdot 7^3 + \cdots$ (digits $1, 2$ repeated)? (Answers: $2, 3, 1, 3, 1, 3$ and $3, 1, 3, 1, 3, 1$; $-5/16$.)

Exercise 7.94. (a) Show that $\mathbb{Q}_p$ is not algebraically closed. (b) Show that $u \in \mathbb{Q}_p^\times$ lies in $\mathbb{Z}_p^\times$ iff u is an m-th power for infinitely many integers $m \geq 1$ (use Theorem 7.20 and Theorem 7.18). (c) Deduce that every field isomorphism $\mathbb{Q}_p \to \mathbb{Q}_{p'}$ maps $\mathbb{Z}_p^\times$ onto $\mathbb{Z}_{p'}^\times$, and that $\mathbb{Q}_p \not\simeq \mathbb{Q}_{p'}$ as fields for $p \neq p'$. (Hints: (a) $X^2 - p$. (b) A unit is $[\bar{u}]u_1$, and u_1 is an m-th power for every m prime to p; an m-th power x has $m \mid v_p(x)$. (c) The characterisation in (b) uses only the field structure. A field isomorphism is the identity on $\mathbb{Q}$, and $p \notin \mathbb{Z}_p^\times$ while $p \in \mathbb{Z}_{p'}^\times$.)

Exercise 7.95. (a) Find the two square roots of -1 in $\mathbb{Z}_{13}$ modulo 13^3. (b) Show that 2 has exactly one cube root in $\mathbb{Z}_5$ and find it modulo 5^3. (c) Show that $X^3 - 3$ has no root in $\mathbb{Z}_7$. (d) Compute the Teichmüller lift $[2] \in \mathbb{Z}_7$ modulo 7^3 and check that it is a root of $X^2 + X + 1$. (Answers: 239, 1958; 53; 324.)

Exercise 7.96. For $d \in \{-7, 6, 14, -15, 17, -3, 13\}$ decide whether $\mathbb{Q}_2(\sqrt{d})$ is $\mathbb{Q}_2$, the unramified quadratic extension, or ramified, and in the last case give the conductor exponent of its character. Compare with the 2-adic valuation of the discriminant of $\mathbb{Q}(\sqrt{d})$. (Answer: $\mathbb{Q}_2$ for -7, -15, 17 ($d \equiv 1 \pmod 8$); unramified for -3, 13 ($d \equiv 5 \pmod 8$); ramified with conductor exponent 3 for $6 \in -10(\mathbb{Q}_2^\times)^2$ and $14 \in -2(\mathbb{Q}_2^\times)^2$. The discriminants $-7, 24, 56, -15, 17, -3, 13$ have 2-adic valuations $0, 3, 3, 0, 0, 0, 0$: in every case the conductor exponent.)

Exercise 7.97. Let p be odd. (a) Show that $(1+p\mathbb{Z}_p)^p = 1+p^2\mathbb{Z}_p$ and that $\mathbb{Q}_p^\times/(\mathbb{Q}_p^\times)^p \simeq (\mathbb{Z}/p)^2$. (b) Compare with the formula $\#K^\times/(K^\times)^{\ell^k} = \ell^k \cdot \#\mu_{\ell^k}(K)$ of Theorem 7.20(iv), valid for $\ell \neq p$; which factor is missing when $\ell = p$? (c) Show that log is not injective on $1+2\mathbb{Z}_2$, and explain why this does not contradict Theorem 7.18(ii). (Hints: (a) log carries $1+p\mathbb{Z}_p$ onto $p\mathbb{Z}_p$ and p-th powers to $p\mathbb{Z}_p \cdot p = p^2\mathbb{Z}_p$. (b) The factor coming from the $\mathbb{Z}_p$ in $\mathbb{Z}_p^\times \simeq \mathbb{Z}/(p-1)\times\mathbb{Z}_p$; for $\ell \neq p$ the corresponding $U^{(1)}$ is ℓ-divisible. (c) $\log(-1) = \frac{1}{2}\log((-1)^2) = 0$; the theorem concerns $1+4\mathbb{Z}_2$ only.)

Exercise 7.98. Determine $\mathbb{Q}_{13}^\times/(\mathbb{Q}_{13}^\times)^3$ and $\mathbb{Q}_{13}^\times/(\mathbb{Q}_{13}^\times)^9$, and decide which of 2, 3, 5, 8, 65 are cubes in $\mathbb{Q}_{13}$. (Answer: $\mathbb{Z}/3\times\mathbb{Z}/3$ and $\mathbb{Z}/9\times\mathbb{Z}/3$, as $v_3(12) = 1$. The cubes of $\mathbb{F}_{13}^\times$ are $\{1,5,8,12\}$, so 5 and 8 are cubes; 2 and 3 are not; $65 = 13\cdot 5$ is not, as $3 \nmid v_{13}(65)$.)

Exercise 7.99. Let $E =$ `11a1`, which has split multiplicative reduction at 11 with $n_{11} = v_{11}(\Delta_E) = 5$. Using Theorem 7.58(v) and Example 7.74, show that I_{11} acts trivially on $E[5]$ but not on $E[25]$ (the paper's Lemma lem:tamagawa-exp). Using Example 7.22(c), show more: $E[5] \simeq \mathbb{Z}/5 \oplus \mu_5$ as a $G_{\mathbb{Q}_{11}}$-module. (Hint: $E[\ell^k]$ is an extension of $\mathbb{Z}/\ell^k$ by μ_{ℓ^k} whose class is $\kappa_{q_E} \bmod \ell^k$; q_E is a fifth power in $\mathbb{Q}_{11}$, so by Proposition 7.57(i) the cocycle modulo 5 is a coboundary, and the extension splits.)

Exercise 7.100. Redo Example 7.55 for $(q,\ell,k) = (5,3,2)$ and $(11,3,2)$: give the order of $\mathrm{Gal}(\mathbb{Q}_q(\mu_9, q^{1/9})/\mathbb{Q}_q)$, and compute $\mathrm{Frob}\; t\; \mathrm{Frob}^{-1}$ and $\mathrm{Frob}^{-1}\, t\; \mathrm{Frob}$ as powers of t. Then show directly, in the affine model, that $\Phi\, t\, \Phi^{-1} = t^{q'}$ for the geometric Frobenius $\Phi = \mathrm{Frob}^{-1}$. (Answers: 5 and $11 \equiv 2$ both have order 6 modulo 9, so both groups have order 54; for $q=5$, t^5 and t^2; for $q=11$, t^2 and t^5.)

Exercise 7.101. The curve $E =$ `14a1`, $y^2+xy+y = x^3+4x-6$, has split multiplicative reduction of type I_3 at 7, and PARI gives the Tate parameter $q_E = 6\cdot 7^3 + 4\cdot 7^4 + 6\cdot 7^5 + \cdots$. Compute n, the reduction $\bar{u}$ of the unit part, the class c of Lemma lem:tamfactor at $\ell = 3$ and $v_3(c)$, and deduce $v_3(\mathrm{Tam}_7(\mathrm{ad}^0\, T_3 E))$ from the lemma. Do the same for `11a1` at $q = 11$, $\ell = 5$. (Answers: 2 in both cases.)

Exercise 7.102. Let $q \neq \ell$ be primes, $x \in \mathbb{Q}_q^\times$ with $v_q(x) = n \geq 1$, and κ the Kummer cocycle of x for a chosen compatible system of ℓ-power roots, with $\mathbb{Z}_\ell(1) \simeq \mathbb{Z}_\ell$. Working directly from the definition of κ (without quoting Theorem 7.58(iv)): (a) show that replacing the system of roots by another one changes κ by the coboundary $g \mapsto (\chi_\ell(g)-1)z$ for some $z \in \mathbb{Z}_\ell$, so that $c' = \kappa(\mathrm{Frob})$ changes by $(q-1)z$; (b) show that replacing Frob by $\mathrm{Frob}\,\sigma$ ($\sigma \in I_q$) changes c' by $q\, n\, t_\ell(\sigma)$; (c) deduce that $\min(v_\ell(n), v_\ell(q-1), v_\ell(c'))$ does not depend on any choice. This is the quantity in the formula of the paper's Lemma lem:tamfactor. (d) For $q=7$, $\ell=3$ and $x = 7^3 u$ with $u \equiv 3 \pmod 7$, compute this minimum. (Answer: 0, since 3 is not a cube in $\mathbb{F}_7^\times$; contrast Exercise 7.101, where $\bar{u} = 6 = (-1)^3$ is a cube.)

Exercise 7.103. Let q be odd, $K = \mathbb{Q}_q(\sqrt{q^*})$ and $\ell \neq q$. (a) Show that I_K has index 2 in I_q and that $t_{\ell,\mathbb{Q}_q}|_{I_K} = 2t_{\ell,K}$. (b) For ρ the Tate shape of Example 7.74 with $x \in \mathbb{Q}_q^\times$, $a = v_q(x)$, show that $\rho \bmod \ell^k$ is unramified on G_K iff $\ell^k \mid 2a$. (c) Conclude that the criterion of Lemma lem:tamagawa-exp is insensitive to this ramified base change for ℓ odd but not for $\ell = 2$, in contrast with the unramified base change of its proof. (Hints: (a) Proposition 7.38 and Theorem 7.47(v) with $e=2$. (b) On I_K, $\kappa_x = a\, t_{\ell,\mathbb{Q}_q} = 2a\, t_{\ell,K}$, and $t_{\ell,K}$ is surjective. (c) For ℓ odd, $\ell^k \mid 2a$ iff $\ell^k \mid a$.)

Exercise 7.104. Let ρ be the Tate shape of Example 7.74 with $a \neq 0$ and $\varepsilon = 1$. Show that $\mathrm{WD}(\mathrm{Sym}^2 \rho) \simeq \mathrm{sp}(3)$, and compute $L(\mathrm{Sym}^2 V, s)$, $\dim(\mathrm{Sym}^2 V)^{I_K}$ and $a(\mathrm{Sym}^2 V)$. Check your answer against $\mathrm{Sym}^2 V \simeq \mathrm{ad}^0 V \otimes \det V$ and Proposition 7.88(iii). (Answer: $L(\mathrm{Sym}^2 V, s) = (1 - q^{-2-s})^{-1}$, $\dim(\mathrm{Sym}^2 V)^{I_K} = 1$, $a(\mathrm{Sym}^2 V) = 2$; indeed $\det V = \chi_\ell$ corresponds to $\|\cdot\|$, and $\mathrm{sp}(3) \otimes \|\cdot\|^{-1} \otimes \|\cdot\| = \mathrm{sp}(3)$.)

Exercise 7.105. The curve `14a1` has multiplicative reduction at 2 and 7. Using Proposition 7.84 and Proposition 7.61, predict the conductors of its quadratic twists by χ_{-4}, χ_8, χ_{-3} and χ_{-7}. (PARI gives 112, 448, 126 and 98.)

Exercise 7.106. `11a1` has type I_5 at 11, and its twist by χ_{-11} is `121d2`, of type I_5^* at 11. Using Theorem 7.89, compute $L_{11}(A_f, 1)^{-1}$ and the naive factor for both curves, and $e_3(E, 11)$, $e_5(E, 11)$. Explain why the true factor is invariant under the twist and the naive one is not (Definition def:terms). (Answer: $L_{11}(A_f, 1)^{-1} = 1 - 11^{-2} = \frac{120}{121}$ for both curves (rows 3 and 4); the naive factor is $\frac{120}{121}$ for `11a1` ($\delta_{11} = 1$) and 1 for `121d2` ($\delta_{11} = 0$); $e_3 = e_5 = 0$ for `11a1` and $e_3 = v_3(120) = 1$, $e_5 = v_5(120) = 1$ for `121d2`. PARI's `elllocalred` confirms the Kodaira type I_5^* of `121d2` at 11.)

Exercise 7.107. For a prime $q \neq 3$ at which $\rho(I_q)$ is cyclic of order 3, $e_3(E, q) = v_3(q - \chi_{-3}(q))$ (Proposition 7.87). Find all such $q < 60$ with $e_3(E, q) \geq 2$, and the largest value of e_3 among them. (Answer: $e_3 \geq 2$ iff $q \equiv \pm 1 \pmod 9$; for $q < 60$ these are 17, 19, 37, 53, with $e_3 = 2, 2, 2, 3$; the largest is $e_3 = 3$ at $q = 53$, as $53 + 1 = 2 \cdot 3^3$.)

Exercise 7.108. Let $L = \mathbb{Q}_3(\zeta_9)$, $G = \mathrm{Gal}(L/\mathbb{Q}_3) \simeq (\mathbb{Z}/9)^\times$. (a) Using $v_L(\zeta^{a-1} - 1) = 3^{v_3(a-1)}$ for $a \not\equiv 1 \pmod 9$, show that $G_0 = G$, $G_1 = G_2$ is the subgroup of order 3, and $G_3 = 1$. (b) Compute the Swan and Artin conductors of the characters of G of orders 2, 3 and 6, and compare with the conductors of the Dirichlet characters modulo 9. (c) Which of them is χ_{-3}? (Answer: (b) the character of order 2 is trivial on G_1, so it is tame with $\mathrm{sw} = 0$, $a = 1$; those of orders 3 and 6 are nontrivial on $G_1 = G_2$ and trivial on G_3, so $\mathrm{sw} = \frac{3}{6} + \frac{3}{6} = 1$ and $a = 2$; the conductors 3 and 9 of the Dirichlet characters agree. (c) The one of order 2.)

Exercise 7.109. Suppose $\rho(I_q) = \langle \tau \rangle$ is cyclic of order 4 with $\det \rho|_{I_q} = 1$ and $q \equiv 3 \pmod 4$. Show that $\mathrm{tr}\, \rho(\mathrm{Frob}) = 0$ for every Frobenius lift, that $\rho(\mathrm{Frob})^2$ commutes with τ, and that $V \otimes \Omega(i)$ is irreducible as a representation of $G_{\mathbb{Q}_q}$. (Hint: $\rho(\mathrm{Frob})$ conjugates τ to $\tau^q = \tau^{-1}$, so it exchanges the i- and $(-i)$-eigenlines of τ; a $G_{\mathbb{Q}_q}$-stable line would be an eigenline of τ fixed by $\rho(\mathrm{Frob})$.)

Exercise 7.110. (a) Show that for $\ell \neq p$ every continuous character $G_K \to \mathbb{Q}_\ell^\times$ has finite image on I_K. (b) Show that the cyclotomic character χ_p of $G_{\mathbb{Q}_p}$ has infinite image on I_p, and explain which step of the proof of Theorem 7.68 fails for $\ell = p$. (Hints: (a) the target is abelian, so $\psi(\mathrm{Frob}\, \sigma\, \mathrm{Frob}^{-1}) = \psi(\sigma)$. Let $U \subseteq I_K$ be the open subgroup mapping into the torsion-free pro-ℓ part of $\mathbb{Z}_\ell^\times$ ($1 + \ell\mathbb{Z}_\ell$, or $1 + 4\mathbb{Z}_2$); U is normal in G_K, and $\psi|_U$ factors through t_ℓ (Corollary 7.48), so the tame relation gives $\psi(\sigma)^q = \psi(\sigma)$ on U. Hence $\psi(U)$ is torsion free and killed by $q - 1$, so trivial. (b) $\chi_p(I_p) = \mathbb{Z}_p^\times$ (Proposition 7.39(ii)); the step that fails is the factorisation through t_ℓ, as I_p has the huge pro-p quotient P_p.)

Exercise 7.111. (a) For p odd, show that $\mathbb{Q}_p(\sqrt{p + p^3}) = \mathbb{Q}_p(\sqrt{p})$, once by Hensel's lemma and once by Lemma 7.31(i). (b) Show that $\mathbb{Q}_2(\sqrt{10}) \neq \mathbb{Q}_2(\sqrt{2})$ although $|\sqrt{10} - \sqrt{2}|_2 = |\sqrt{2} - (-\sqrt{2})|_2$: the strict inequality in Krasner's lemma cannot be relaxed. (Hints: (a) $(p + p^3)/p = 1 + p^2$

is a square in $\mathbb{Z}_p$; and choosing the sign with $\sqrt{p+p^3}/\sqrt{p} \equiv 1 \pmod p$, $|\sqrt{p+p^3} - \sqrt{p}|_p = |p^3|_p/|\sqrt{p+p^3} + \sqrt{p}|_p = p^{-5/2}$, less than $|\sqrt{p} - (-\sqrt{p})|_p = p^{-1/2}$. (b) $10/2 = 5$ is not a square in $\mathbb{Q}_2$.)

7.11 Notes and references

Absolute values, completions, $\mathbb{Q}_p$, Hensel's lemma and the structure of $\mathbb{Q}_p^\times$ follow Serre's *A Course in Arithmetic* [172, Chapter II] and Neukirch [142, Chapter II, Sections 1 to 5]; the factorisation form of Hensel's lemma and its corollary on coefficients of irreducible polynomials are in Neukirch, Chapter II, Section 4, and many variants are collected in Keith Conrad's notes [33]. Cassels' chapter "Global fields" in Cassels and Fröhlich [26] is a compact alternative. Extensions of the absolute value, e and f, Eisenstein polynomials, unramified and tamely ramified extensions, and Krasner's lemma follow Serre's *Local Fields* [174, Chapters I to IV] and Neukirch, Chapter II, Sections 6 to 10; the comparison of completions of number fields with the global theory (Theorem 7.30, Proposition 7.32) is Neukirch, Chapter II, Sections 8 and 9.

The ramification groups, their quotients and the tame character are Serre [174, Chapter IV, Sections 1 and 2]; Herbrand's theorem, upper numbering and Hasse-Arf are Chapter IV, Section 3, and Chapter V, Section 7 there; the Artin and Swan conductors and Artin's integrality theorem are Chapter VI, Section 2, and the representation-theoretic side is in [173, Chapter 19]. The structure of $\mathrm{Gal}(K^{\mathrm{tame}}/K)$ as a profinite group with two generators is in Neukirch, Schmidt and Wingberg [143, Chapter VII, Section 5]. The use of the tame quotient and of Kummer classes for ℓ-adic representations, and the Tate curve, are in Serre [178, Chapters I and IV] and Silverman [184, Chapter V]; Serre and Tate [179, Sections 1 and 2] prove Grothendieck's theorem in the form used here (their appendix), the criterion of Néron, Ogg and Shafarevich, and the independence of ℓ of the image of inertia for potentially good reduction. Local class field theory is stated after Serre's chapter in [26] and Milne [133, Chapter I].

Weil-Deligne representations, local L-factors, conductors and epsilon factors follow Deligne [41, Section 8] and Tate [194, Section 4]; Rohrlich [166] is a gentle account written for elliptic curves, with the classification of two-dimensional representations. The convention that local L-factors use the geometric Frobenius is the one of [49, Section 1.7.2], which the paper follows.

All chapter and section numbers of books cited in this chapter (Serre, Neukirch, Neukirch-Schmidt-Wingberg, Milne, Cassels-Fröhlich, Silverman, Deligne, Tate, Rohrlich) are recalled and were not checked against printed copies; they are pointers, and no proof in the chapter depends on them. No theorem numbers from these sources are cited. Every numerical example and the answers to the exercises were checked with PARI/GP [148] through `cypari2`, with commands such as the following.

Part III

Curves and elliptic curves

Chapter 8

Algebraic curves, function fields and Riemann surfaces

The paper's objects live on curves: the modular curve $X_0(N)$, the elliptic curve E, the modular parametrisation $\varphi_E\colon X_0(N) \to E$ and its degree, the cohomology $H^1(X_0(N), \mathbb{Z}_\ell)$ with its cup product, and the Jacobian $J_0(N)$ with its torsion and Tate modules. This chapter supplies the theory of curves that these words presuppose, in two languages: algebraic (varieties, function fields, divisors, differentials, Riemann-Roch, morphisms and their degree, Riemann-Hurwitz), in the classical style of Silverman's book, and analytic (compact Riemann surfaces, holomorphic forms, periods, H_1, H^1 and the cup product, the Jacobian as a complex torus), joined by Riemann's existence theorem. It ends with correspondences and the theorem that the adjoint of a correspondence for the cup product is its transpose, which is what makes the Hecke operators self-adjoint for the pairing of Section 4.1 of the paper. It uses Chapter 1 (inverse limits, $\mathbb{Z}_\ell$, Moebius maps), Chapter 2 (polynomial rings, finite fields), Chapter 3 (Nakayama, discrete valuation rings, lattices, saturation, perfect and alternating pairings, adjoints, idempotents), Chapter 4 (contragredients), Chapter 5 (separability, Hilbert 90) and Chapter 6 (the identity $\sum e_i f_i = n$), and the complex analysis of Appendix A.

Core results at a glance

Throughout, k is a perfect field, C a smooth projective curve over k of genus g, X, Y compact Riemann surfaces, $\varphi\colon X \to Y$ a nonconstant morphism of degree n, $\langle\ ,\ \rangle$ the cup product, $A^\dagger$ the adjoint of an operator, and $\mathcal{C} = (C, \alpha, \beta)$ a correspondence with transpose $\mathcal{C}^t = (C, \beta, \alpha)$.

8.1 Conventions. G_k acts on points coordinatewise; φ^* is pullback, φ_* pushforward, $A^\dagger$ an adjoint; cup product $\int_X \theta \wedge \eta$ with the complex orientation; π_q the Frobenius morphism; $l(D)$ the dimension of $\mathcal{L}(D)$. Convention 8.1.

8.2 Affine varieties (definition): zero sets $V(S) \subseteq \mathbb{A}^n(\bar{k})$ with $I(V)$ prime; coordinate ring, function field, dimension = transcendence degree; defined over k. Definition 8.2.

8.3 Nullstellensatz. $I(V(\mathfrak{a})) = \sqrt{\mathfrak{a}}$; for k perfect, V is defined over k iff $\sigma(V) = V$ for all $\sigma \in G_k$. *(stated; reference)* Theorem 8.3.

8.4 Projective varieties (definition): $\mathbb{P}^n = (\bar{k}^{n+1} \setminus 0)/\bar{k}^\times$, homogeneous ideals, charts $U_i \simeq \mathbb{A}^n$, projective closure, function field of quotients of forms of equal degree. Definition 8.4.

8.5 Points over subfields. $\mathbb{P}^n(\bar{k})^{G_L} = \mathbb{P}^n(L)$; $\mathbb{P}^n = \mathbb{A}^n \sqcup \mathbb{P}^{n-1}$; the function field of a projective variety is that of any affine chart. *(proved here)* Proposition 8.5.

8.6 Curves, rational maps, morphisms (definition): a curve is a projective variety of dimension one defined over k; morphisms are rational maps regular everywhere; defined over k iff Galois-equivariant. Definition 8.6.

8.7 Plane curves (definition): $V(F)$, F homogeneous and irreducible over $\bar{k}$; P singular iff $F_X = F_Y = F_Z = 0$ at P. Definition 8.8.

8.8 Affine criterion. $XF_X + YF_Y + ZF_Z = dF$; an affine point is singular iff $f = f_x = f_y = 0$; tangent line $F_X(P)X + F_Y(P)Y + F_Z(P)Z = 0$. *(proved here)* Proposition 8.9.

8.9 Smooth points are discrete valuations. P smooth iff $\dim \mathfrak{m}_P/\mathfrak{m}_P^2 = 1$ iff $\bar{k}[C]_P$ is a discrete valuation ring; a line other than the tangent gives a uniformiser; ord_P is the order of vanishing. *(proved here for plane models; general case stated)* Theorem 8.11.

8.10 Bezout. Plane curves of degrees m, n without common component meet in mn points with multiplicity. *(stated; reference)* Theorem 8.12.

8.11 Smooth models. Every curve is birational over k to a unique smooth projective curve; its points are the valuations of the function field. *(stated; reference)* Theorem 8.13.

8.12 Function fields (definition): finitely generated of transcendence degree one with k algebraically closed in it. Definition 8.14.

8.13 Valuations. Each point gives ord_P; a function has finitely many zeros and poles; a function without poles is constant. *(proved here, given the finiteness of proper closed subsets)* Proposition 8.15.

8.14 Extension of morphisms. A rational map from a smooth curve to a projective variety is a morphism; every $f \in \bar{k}(C)$ is a morphism $C \to \mathbb{P}^1$. *(proved here)* Theorem 8.16.

8.15 Curves and function fields. $C \mapsto k(C)$ is a contravariant equivalence between smooth projective curves with nonconstant morphisms over k and function fields of one variable over k; a morphism of degree one is an isomorphism. *(stated; reference)* Theorem 8.17.

8.16 Galois action. $C(\bar{k})^{G_L} = C(L)$; $(\sigma f)(\sigma P) = \sigma(f(P))$ and $\mathrm{ord}_{\sigma P}\, \sigma f = \mathrm{ord}_P f$; morphisms over k commute with G_k. *(proved here; the fixed field $k(C)$ stated)* Proposition 8.18.

8.17 Divisors (definition): $\mathrm{Div}(C)$, degree, $\mathrm{Div}_k(C) = \mathrm{Div}(C)^{G_k}$, $\mathrm{div}(f) = \sum \mathrm{ord}_P(f)(P)$. Definition 8.21.

8.18 Principal divisors. $\deg \mathrm{div}\, f = 0$ iff f is constant; $\deg \mathrm{div}\, f = 0$, with $\deg \mathrm{div}_0 f = \deg \mathrm{div}_\infty f = [\bar{k}(C) : \bar{k}(f)]$; on $\mathbb{P}^1$, $\mathrm{div}(x - a) = (a) - (\infty)$. *(proved here, given Theorem 8.38)* Proposition 8.22.

8.19 Picard group (definition): $\mathrm{Pic}(C) = \mathrm{Div}(C)/\mathrm{Prin}(C)$, $\mathrm{Pic}^0(C)$ the degree-zero part. Definition 8.23.

8.20 The Picard group. $\mathrm{Pic}^0(\mathbb{P}^1) = 0$; G_k acts; $\mathrm{Div}_k^0(C)/\mathrm{div}(k(C)^\times) \to \mathrm{Pic}^0(C)^{G_k}$ is injective *(proved here)*, and bijective if $C(k) \neq \emptyset$ *(stated; reference)*. Proposition 8.24.

8.21 Differentials (definition): Ω_C, $\operatorname{ord}_P \omega$, $\operatorname{div}\omega$, regular differentials. Definition 8.25.

8.22 Differentials and the canonical class. Ω_C is one-dimensional, ord_P is well defined *(stated; reference)*; all $\operatorname{div}\omega$ form one class K_C; on $\mathbb{P}^1$, $\operatorname{div}(dx) = -2(\infty)$; on $y^2 = h(x)$, $\operatorname{div}(dx/y) = 0$ *(proved here)*. Proposition 8.26.

8.23 Riemann-Roch spaces (definition): $\mathcal{L}(D) = \{f : \operatorname{div} f + D \geq 0\} \cup \{0\}$, $l(D) = \dim \mathcal{L}(D)$. Definition 8.27.

8.24 Riemann-Roch spaces. $\mathcal{L}(0) = \bar{k}$; $\mathcal{L}(D) = 0$ if $\deg D < 0$; $l(D + (P)) \leq l(D) + 1$, so $l(D) \leq \deg D + 1$ for $D \geq 0$; l depends on the class; for D over k, $\mathcal{L}(D)$ has a k-rational basis *(proved here; the rational basis stated)*. Proposition 8.28.

8.25 Riemann-Roch. $l(D) - l(K_C - D) = \deg D - g + 1$. *(stated; reference, with the shape of the proof)* Theorem 8.29.

8.26 Consequences. $l(K_C) = g$; $\deg K_C = 2g - 2$; $l(D) = \deg D - g + 1$ if $\deg D > 2g - 2$; genus 0 with a rational point means $\mathbb{P}^1$; for $g = 1$, $l(D) = \deg D$ ($\deg D \geq 1$), $K_C \sim 0$, and regular differentials have no zeros. *(proved here)* Corollary 8.30.

8.27 Plane curves. A smooth plane curve of degree d has genus $(d-1)(d-2)/2$, in any characteristic. *(proof sketched here)* Theorem 8.31.

8.28 Weierstrass equations. A genus-one curve C with $O \in C(k)$ is isomorphic over k, by $[x : y : 1]$ with $x \in \mathcal{L}(2(O))$, $y \in \mathcal{L}(3(O))$, to a smooth Weierstrass cubic $y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6$, $a_i \in k$, with $O \mapsto [0 : 1 : 0]$; conversely. *(proved here, given that images of projective varieties are closed; the converse in characteristic 2 rests on the sketched Theorem 8.31)* Theorem 8.33.

8.29 Genus one is Pic^0. For $g = 1$ and $O \in C(k)$, $P \mapsto [(P) - (O)]$ is a G_k-equivariant bijection $C(\bar{k}) \to \operatorname{Pic}^0(C)$. *(proved here)* Proposition 8.34.

8.30 Nonconstant morphisms. A morphism of curves is constant or surjective *(stated; reference)*; φ^* embeds $\bar{k}(C_2)$ in $\bar{k}(C_1)$ with finite index *(proved here)*. Theorem 8.36.

8.31 Degree, ramification, pullback (definition): $\deg\varphi = [\bar{k}(C_1) : \varphi^*\bar{k}(C_2)]$; $e_\varphi(P) = \operatorname{ord}_P(\varphi^* t_{\varphi(P)})$; $\varphi^*(Q) = \sum_{\varphi(P)=Q} e_\varphi(P)(P)$; $\varphi_*(P) = (\varphi(P))$. Definition 8.37.

8.32 Degree formula. $\sum_{P\mapsto Q} e_\varphi(P) = \deg\varphi$ for every Q. *(proof sketched here)* Theorem 8.38.

8.33 The degree in three ways. Field degree; $\#\varphi^{-1}(Q) = \deg\varphi$ off the branch points for separable φ; $\deg\varphi^* D = \deg\varphi \deg D$, $\varphi_*\varphi^* = \deg\varphi$, $\varphi^* \operatorname{div} f = \operatorname{div}\varphi^* f$, so $\varphi_*\varphi^* = [\deg\varphi]$ on Pic^0; degrees multiply; degree one means isomorphism; a function without poles is constant. *(proved here, given Theorem 8.38; the norm formula and the inseparable case stated)* Corollary 8.39.

8.34 Separability and Frobenius. Characteristic 0 morphisms are separable *(proved here)*; separable iff $\varphi^*\omega \neq 0$, and the factorisation through Frobenius *(stated; reference)*; π_q is a purely inseparable bijection of degree q with $e = q$ everywhere, fixed points $C(\mathbb{F}_q)$, acting on points as Frob_q *(proved here; the degree sketched)*. Proposition 8.40.

8.35 Ramification (definition): unramified, branch points, tame and wild. Definition 8.42.

8.36 Local computation. For separable φ, $\operatorname{ord}_P \varphi^*\omega = e \operatorname{ord}_Q \omega + \operatorname{ord}_P(d(\varphi^* t_Q)/dt_P)$ with the last term $\geq e-1$, equality iff tame; finitely many ramified points. *(proved here, given Proposition 8.40(b) and Theorem 8.38)* Lemma 8.43.

8.37 Riemann-Hurwitz. $2g_1 - 2 \geq \deg\varphi(2g_2-2) + \sum_P (e_\varphi(P)-1)$ for separable φ, with equality iff all ramification is tame. *(proved here, given Theorem 8.38 and Riemann-Roch)* Theorem 8.44.

8.38 Consequences. $g_1 \geq g_2$ if $g_2 \geq 1$; morphisms of genus-one curves are unramified; hyperelliptic and Fermat genera; for $\varphi\colon X \to E$, $\sum(e_P - 1) = 2g(X) - 2$ (for $\varphi_{\texttt{121a1}}$: 10; $\varphi_{\texttt{539c1}}$: 96). *(proved here, given Theorem 8.44)* Corollary 8.45.

8.39 Riemann surfaces (definition): charts with holomorphic transitions; meromorphic functions; holomorphic maps. Definition 8.46.

8.40 Holomorphic maps. Local normal form $w = z^e$; open, surjective, finite fibres; constant degree $\sum_{P\mapsto Q} \operatorname{mult}_P$; finitely many ramification points; orientation-preserving. *(proved here)* Theorem 8.48.

8.41 Riemann existence and GAGA. Compact Riemann surfaces and smooth projective complex curves are equivalent, compatibly with functions, orders, multiplicities, degrees, differentials, divisors and genus. *(stated; reference)* Theorem 8.49.

8.42 Topology. A compact Riemann surface is a sphere with g handles, $\chi = 2-2g$ *(stated; reference)*; $\chi(X) = d\chi(Y) - \sum(\operatorname{mult}_P - 1)$ *(proof sketched here)*. Theorem 8.50.

8.43 1-forms (definition): meromorphic and holomorphic 1-forms, residues, $H^0(X,\Omega^1)$, smooth forms and Stokes. Definition 8.51.

8.44 Residue theorem. $\sum_P \operatorname{res}_P \omega = 0$. *(proved here)* Theorem 8.52.

8.45 Argument principle. $\deg\operatorname{div} f = \sum \operatorname{res}(df/f) = 0$. *(proved here)* Corollary 8.53.

8.46 Genus and forms. $\dim H^0(X,\Omega^1) = g$; $\deg\operatorname{div}\omega = 2g-2$. *(proved here from Riemann-Roch and GAGA, both stated)* Theorem 8.54.

8.47 Bilinear relations. $\int \omega\wedge\eta = 0$ and $\frac{i}{2}\int \omega\wedge\bar\omega > 0$ for holomorphic forms; $\int \theta\wedge\eta = \sum_j (A_j(\theta)B_j(\eta) - B_j(\theta)A_j(\eta))$ *(proof sketched here)*; Riemann's relations; the periods form a lattice Λ_X *(proved here, given the sketched identity)*. Theorem 8.55.

8.48 First homology (definition): $H_1(X,\mathbb{Z})$, φ_*, $H_1(X,A) = H_1 \otimes A$. Definition 8.56.

8.49 Symplectic bases. $H_1(X,\mathbb{Z}) \simeq \mathbb{Z}^{2g}$ with a symplectic basis; the intersection pairing is perfect and alternating, $a_i \cdot b_j = \delta_{ij}$. *(stated; reference)* Theorem 8.57.

8.50 First cohomology (definition): $H^1(X,A) = \operatorname{Hom}(H_1(X,\mathbb{Z}),A)$; φ^* the transpose of φ_*; de Rham classes; H^2. Definition 8.58.

8.51 Cohomology. $H^1(X,\mathbb{Z}_\ell) = H^1(X,\mathbb{Z}) \otimes \mathbb{Z}_\ell$ free of rank $2g$ *(proved here)*; de Rham and $H^2(X,\mathbb{Z}) = \mathbb{Z}$ *(stated; reference)*; Hodge $H^1(X,\mathbb{C}) = H^0(\Omega^1) \oplus \overline{H^0(\Omega^1)}$ *(proof sketched here)*; $H^1(X,M) = H^1(\pi_1(X),M)$ *(stated; reference)*. Proposition 8.59.

8.52 Cup product. $\langle\theta,\eta\rangle = \int_X \theta\wedge\eta$ is integral, alternating and perfect on $H^1(X,\mathbb{Z})$ with Gram matrix $\left(\begin{smallmatrix} 0 & I_g \\ -I_g & 0\end{smallmatrix}\right)$, and after any base change, in particular on $H^1(X,\mathbb{Z}_\ell)$; Poincare duality $\mathrm{PD}(a_j^\vee) = b_j$, $\mathrm{PD}(b_j^\vee) = -a_j$ is an isometry. *(proved here, given Theorem 8.57 and Theorem 8.55(c))* Theorem 8.60.

8.53 Transfer and projection formula. $\varphi^!\colon H_1(Y)\to H_1(X)$ with $\varphi_*\varphi^! = n$ *(proof sketched here)*; φ_* on H^1 (transpose of $\varphi^!$, the trace of forms); $\langle\varphi_*\eta,\xi\rangle = \langle\eta,\varphi^*\xi\rangle$, $\varphi_*\varphi^* = n$, $\langle\varphi^*x,\varphi^*y\rangle = n\langle x,y\rangle$, $\varphi^* = n$ on H^2 *(proved here)*. Proposition 8.62.

8.54 Which is dual to which. H_1, Λ_X, J, $J[n]$, $T_\ell J$ covariant; $H^1 = \mathrm{Hom}(T_\ell J,\mathbb{Z}_\ell)$, $H^0(\Omega^1)$ contravariant; PD turns $\mathcal{C}^*$ into $(\mathcal{C}^t)_*$; $H^1_{\mathrm{et}} \simeq T_\ell J(-1)$. Convention 8.63.

8.55 Jacobian (definition): $J(C)(\bar k) = \mathrm{Pic}^0(C)$; $J_{\mathrm{an}}(X) = H^0(X,\Omega^1)^\vee/\Lambda_X$. Definition 8.65.

8.56 Abel-Jacobi. AJ: $\mathrm{Div}^0(X)\to J_{\mathrm{an}}(X)$ is a well-defined homomorphism and $\iota\colon X\to J_{\mathrm{an}}$ is a holomorphic injection inducing the period isomorphism on H_1 *(proved here, injectivity given Abel's theorem)*; Abel's theorem and Jacobi inversion, $\mathrm{Pic}^0(X)\simeq J_{\mathrm{an}}(X)$ *(stated; reference)*. Theorem 8.66.

8.57 Jacobian variety. J is an abelian variety of dimension g over k with $J(\bar k) = \mathrm{Pic}^0(C)$, $J(\mathbb{C}) = J_{\mathrm{an}}$, the Albanese universal property, and Mordell-Weil. *(stated; reference)* Theorem 8.67.

8.58 Functoriality. $\varphi_*\colon J(X)\to J(Y)$ and $\varphi^*\colon J(Y)\to J(X)$ with $\varphi_*\varphi^* = [n]$; over $\mathbb{C}$, φ_* is induced by $(\varphi^*)^\vee$ and φ_* on H_1 *(proved here)*, φ^* by the trace and $\varphi^!$ *(proof sketched here)*; for $Y = E$, $\varphi = \varphi_*\circ\iota_X$. Proposition 8.68.

8.59 Tori. For a surjective map of complex tori, $\pi_0(\ker)\simeq M/A(\Lambda)$; for $B\colon W\to V$ $\mathbb{C}$-linear and injective with $B(M)\subseteq\Lambda$, $\ker\simeq \mathrm{sat}(B(M))/B(M)$; maps of one-dimensional tori are $z\mapsto cz$ of degree $[\Lambda' : c\Lambda]$. *(proved here)* Lemma 8.69.

8.60 Degree and cup product. $\langle\varphi^*x,\varphi^*y\rangle = n\langle x,y\rangle$; $\varphi_*\varphi^* = n$; $\varphi^*H^1(Y,\mathbb{Z})$ saturated iff φ_* onto on H_1 iff $\ker(J(X)\to J(Y))$ connected iff φ^* injective on J, the indices all equal; for $Y = E$, the cup product on $\varphi^*H^1(E)$ has ideal of values $n\mathbb{Z}$, Gram determinant n^2, $[H^1 : M\oplus M^\perp] = n^2$ if saturated, and ideal $(n/m_0)\mathbb{Z}$ on the saturation in general, $m_0 = \#\pi_0(\ker(J(X)\to E))$; an isogeny of degree m destroys saturation. *(proved here; the identification of φ^* on J sketched)* Proposition 8.70.

8.61 Torsion. $J(X)[n] = \frac{1}{n}\Lambda_X/\Lambda_X \simeq H_1(X,\mathbb{Z}/n)\simeq(\mathbb{Z}/n)^{2g}$; $J[\mathfrak{m}]$ is a $\mathbb{T}/\mathfrak{m}$-vector space *(proved here)*; $J[n](\bar k)\simeq(\mathbb{Z}/n)^{2g}$ over k, $\mathrm{char}\,k\nmid n$ *(stated; reference)*. Proposition 8.71.

8.62 Tate modules (definition): $T_\ell J = \varprojlim J[\ell^m]$, $V_\ell J = T_\ell J\otimes\mathbb{Q}_\ell$. Definition 8.72.

8.63 Tate module and H^1. $T_\ell J\simeq H_1(X,\mathbb{Z}_\ell)$, free of rank $2g$; $H^1(X,\mathbb{Z}_\ell) = \mathrm{Hom}_{\mathbb{Z}_\ell}(T_\ell J,\mathbb{Z}_\ell)$; PD gives $H^1\simeq T_\ell J$, not Galois-equivariant, turning $\mathcal{C}^*$ into $(\mathcal{C}^t)_*$ *(proved here)*; over k, $T_\ell J$ free of rank $2g$ with G_k-action *(stated; reference)*. Proposition 8.73.

8.64 Weil pairing and etale cohomology. $e_\ell\colon T_\ell J\times T_\ell J\to\mathbb{Z}_\ell(1)$ perfect alternating equivariant; $H^1_{\mathrm{et}} = (T_\ell J)^\vee\simeq T_\ell J(-1)$, comparison with $H^1(C(\mathbb{C}),\mathbb{Z})\otimes\mathbb{Z}_\ell$; for E, $H^1(E,\mathbb{Z}_\ell)\simeq T_\ell E(-1)$ with determinant χ_ℓ^{-1}; Weil's theorem over $\mathbb{F}_q$ and $a_q = \mathrm{tr}(\mathrm{Frob}_q \mid T_\ell E) = \mathrm{tr}(\mathrm{Frob}_q^{-1}\mid H^1)$. *(stated; reference)* Theorem 8.74.

8.65 Correspondences (definition): $\mathcal{C} = (C, \alpha, \beta)$, transpose (C, β, α), graphs, $u\mathcal{C}v$. Definition 8.78.

8.66 Actions (definition): $\mathcal{C}_* = \beta_*\alpha^*$ on divisors and J, $\mathcal{C}_* = \beta_*\alpha^!$ on H_1, $\mathcal{C}^* = \alpha_*\beta^*$ on H^1 and on differentials. Definition 8.79.

8.67 Compatibilities. $\mathcal{C}^*$ on H^1 is the transpose of $\mathcal{C}_*$ on H_1; graphs act by φ^*, φ_*, $\varphi^!$; $u\mathcal{C}v$ acts by $u_*\mathcal{C}_*v_*$ and $v^*\mathcal{C}^*u^*$ *(proved here)*; the action on J and $T_\ell J$ is $\mathcal{C}_*$ *(proof sketched here)*. Proposition 8.80.

8.68 The adjoint is the transpose. $\langle \mathcal{C}^*\xi, \eta\rangle_X = \langle \xi, (\mathcal{C}^t)^*\eta\rangle_Y$, that is $(\mathcal{C}^*)^\dagger = (\mathcal{C}^t)^*$; automorphisms are isometries; $\mathrm{PD} \circ \mathcal{C}^* = (\mathcal{C}^t)_* \circ \mathrm{PD}$. *(proved here, given Proposition 8.62)* Theorem 8.81.

8.69 Twisted pairing. If $t^t = w^*tw^*$ for every t in a commutative $\mathbb{Z}_\ell$-subalgebra $\mathbb{T}$ of $\mathrm{End}_{\mathbb{Z}_\ell}(H^1(X, \mathbb{Z}_\ell))$ spanned by actions of correspondences, w an involution of X, then $\langle x, w^*y\rangle$ is perfect and alternating on $H^1(X, \mathbb{Z}_\ell)$, every $t \in \mathbb{T}$ is self-adjoint for it, and $H^1(X, \mathbb{Z}_\ell) = \bigoplus_{\mathfrak{m}} H^1(X, \mathbb{Z}_\ell)_{\mathfrak{m}}$ is orthogonal with the pairing perfect on each summand. *(proved here)* Corollary 8.82.

Where the paper uses this chapter

- **Abstract and Section 1** (the modular parametrisation $\varphi_E\colon X_0(N) \to E$, the $X_0(N)$-optimal curve "for which the modular parametrisation $\varphi_E\colon X_0(N) \to E$ has minimal degree", the modular degree $\deg \varphi_E$): morphisms and their degree in every sense, Definition 8.37, Theorem 8.38, Corollary 8.39, Table 8.1, Theorem 8.49; Riemann-Hurwitz checks of the quoted degrees, Corollary 8.45(e); why the optimal curve has minimal degree, Proposition 8.70(iv), (v) and Paper link 8.76.

- **Remark rem:degree (Section 4, sec:quant)** (the formula of Zagier and Watkins: Petersson norm over the area of the period lattice): positivity and periods, Theorem 8.55, Example 8.61.

- **Section 1.1 and Proposition prop:ns** ($\rho_{E,\ell}$ and the action of $G_{\mathbb{Q}}$ on $E[3]$ and on the roots of the 3-division polynomial): the Galois action on points, Proposition 8.18, Paper link 8.20.

- **Appendix app:repro** (curves given by Weierstrass coefficients, `ellinit`): Theorem 8.33, Proposition 8.34, Paper link 8.35.

- **Section 4.1 (sec:dfg)** ("perfect and alternating on $H^1(X_0(M^\Sigma), \mathbb{Z}_\ell)$, and the Hecke operators, U_p included, are self-adjoint for it, because $w_{M^\Sigma}T_n w_{M^\Sigma}^{-1}$ is the adjoint of T_n for the cup product"): Theorem 8.60, Definition 8.79, Theorem 8.81, Corollary 8.82, Paper link 8.64, Paper link 8.84.

- **Proposition prop:pullback** (φ^* injective with image $H^1(X_0(N), \mathbb{Z}_\ell)[I_f]$; $\langle \varphi^*a, w_N^*\varphi^*b\rangle = \varepsilon_N(f)\deg\varphi_E\langle a, b\rangle_E$; the congruence ideal is $\deg\varphi_E\,\mathbb{Z}_\ell$): optimality as connectedness, saturation and surjectivity on H_1, Lemma 8.69, Proposition 8.70(iii); the projection formula, Proposition 8.62(iv); Hodge, Proposition 8.59(iii); unimodularity, Theorem 8.60; step-by-step reading in Paper link 8.76.

- **The paragraph after Proposition prop:pullback and Section 4.2** ($M_{f,\lambda} = H^1(E, \mathbb{Z}_\ell)$, which is $\mathrm{Hom}(T_\ell E, \mathbb{Z}_\ell) \simeq T_\ell E(-1)$; "its adjoint is $\mathrm{ad}^0 T_\ell E$"): Proposition 8.73(ii); Theorem 8.74(b), (c); Warning 8.75; Paper link 8.77.
- **Lemma lem:hecke, Lemma lem:ddt417 as applied, and Step 2 of the proof of Theorem thm:quant** ($L = H^1(X_0(N), \mathbb{Z}_\ell)_{\mathfrak{m}}$ "with a perfect $\mathcal{O}$-bilinear pairing for which $\mathbb{T}$ is self-adjoint"; "the idempotent $e_{\mathfrak{m}}$ is self-adjoint for $\hat{\delta}_!$, so $H^1(X_0(N), \mathbb{Z}_\ell)$ splits orthogonally into its local components and the pairing is perfect on each"): Corollary 8.82(iii).
- **Remark rem:free** ($J_0(N)[\mathfrak{m}]$ two-dimensional, the Tate module free of rank two, $T_\ell J_0(N)$ versus $H^1(X_0(N), \mathbb{Z}_\ell)$ through Poincare duality composed with w_N, not Galois equivariant): Proposition 8.71, Proposition 8.73, Theorem 8.81(c), Warning 8.75, Paper link 8.77.

8.1 Affine and projective varieties

This section fixes the language. A reader who knows complex analysis and linear algebra meets here algebraic geometry and algebraic topology at once, so the chapter keeps two languages and one dictionary. The *algebraic* side is the classical language of Silverman [185, Chapters I and II]: a variety is the set of its points over an algebraic closure $\bar{k}$, cut out by polynomials, with the Galois group G_k acting on coordinates; no schemes, no sheaves and no sheaf cohomology are used. The *analytic* side (Sections 8.8 to 8.10) is the theory of compact Riemann surfaces with charts, as in a first course in complex analysis. The dictionary between the two (Riemann's existence theorem and GAGA) is stated once, in Theorem 8.49, and every other comparison is proved from it. What is proved: every statement that is a computation with polynomials, valuations, local normal forms of holomorphic maps, change of variables in integrals, or linear algebra of lattices. What is sketched: the formula $\sum e_P = \deg \varphi$, the genus of plane curves, the degree of the Frobenius morphism, the topological form of Riemann-Hurwitz, Riemann's bilinear relations, the Hodge decomposition, the transfer, the description of φ^* on the Jacobian by the trace and the transfer, and the action of correspondences on the Jacobian. What is stated with a reference: the Nullstellensatz, Bezout's theorem, the equivalence between curves and function fields, Riemann-Roch, Riemann existence and GAGA, the classification of surfaces, Abel's theorem and Jacobi inversion, the algebraicity of the Jacobian, the Weil pairing and etale cohomology. In the paper the objects of this section are the background of every sentence that mentions $X_0(N)$, E or $E(\bar{\mathbb{Q}})$.

Convention 8.1 (conventions of this chapter)**.**

(C1) *Fields.* k is a perfect field ($\mathbb{Q}$, $\mathbb{Q}_p$, a number field, a finite field $\mathbb{F}_q$ with q a power of a prime p: here q is always the size of a finite field, Appendix B, B-C1); $\bar{k}$ is an algebraic closure and $G_k = \mathrm{Gal}(\bar{k}/k)$ (Chapter 5). Over $\mathbb{C}$ we write X for a compact Riemann surface and identify it with the smooth projective curve it defines (Theorem 8.49).

(C2) *Curves.* A *curve over* k is a projective variety of dimension one defined over k; "variety" includes "irreducible over $\bar{k}$". Unless said otherwise curves are smooth and projective; a singular or affine curve birational to C is called a *model* of C. Morphisms are defined over k when k is named, over $\bar{k}$ otherwise. The genus is g.

(C3) *Points and Galois.* $C(L)$ is the set of points with coordinates in L, for $k \subseteq L \subseteq \bar{k}$; $\sigma \in G_k$ acts on $C(\bar{k})$ coordinatewise, on the left, and $C(L) = C(\bar{k})^{G_L}$. This is the action behind $\rho_{E,\ell}$ (Chapters 9 and 11).

(C4) *Pullback, pushforward, transpose, adjoint.* For a nonconstant morphism $\varphi\colon X \to Y$, φ^* is pullback (of functions, divisors, divisor classes, differentials, classes in H^1) and φ_* is pushforward (of divisors, divisor classes, classes in H_1, and on H^1 the transpose of the transfer, Proposition 8.62). A correspondence is $\mathcal{C} = (C, \alpha, \beta)$ and its transpose $\mathcal{C}^t = (C, \beta, \alpha)$. The adjoint of an endomorphism A for a pairing is $A^\dagger$, never A^*, because a star after the name of a map is a pullback (Appendix B, B-C4).

(C5) *Duals.* $M^\vee = \mathrm{Hom}(M, \mathbb{Z})$ or $\mathrm{Hom}_{\mathbb{Z}_\ell}(M, \mathbb{Z}_\ell)$ for lattices; $V^\vee$ for linear duals and contragredients (Chapter 4). Pontryagin duals do not occur in this chapter.

(C6) *Orientation and the cup product.* A Riemann surface is oriented by its complex structure: in a chart $z = x + iy$ the form $dx \wedge dy = \frac{i}{2} dz \wedge d\bar{z}$ is positive. The cup product of classes in H^1 is $\langle \theta, \eta \rangle = \int_X \theta \wedge \eta$ (de Rham representatives). The intersection number $a \cdot b$ of transverse oriented loops counts crossings with sign $+1$ when (tangent of a, tangent of b) is a positive basis. Poincare duality $\mathrm{PD}\colon H^1 \to H_1$ is fixed by $\int_{\mathrm{PD}(\theta)} \eta = \langle \theta, \eta \rangle$. Other books use other signs; the paper needs only properties that do not change under a global sign (perfectness, alternation, adjointness, ideals of values, Gram determinants in even rank), Appendix B, B-C5(d).

(C7) *Frobenius.* The arithmetic Frobenius Frob_q of $G_{\mathbb{F}_q}$ raises coordinates of $\bar{\mathbb{F}}_q$-points to the q-th power; the q-power Frobenius *morphism* of a curve over $\mathbb{F}_q$ is π_q; the geometric Frobenius is Frob_q^{-1} (Appendix B, B-C2).

(C8) *Notation.* We write $l(D)$, not $\ell(D)$, for the dimension of a Riemann-Roch space, because ℓ is a prime; K_C is a canonical divisor and K a field; D is always a divisor. "Riemann-Roch", "Riemann-Hurwitz", "Abel-Jacobi" take plain hyphens.

Definition 8.2 (affine varieties)**.** Let $\mathbb{A}^n = \mathbb{A}^n(\bar{k}) = \bar{k}^n$, with G_k acting coordinatewise, so that $\mathbb{A}^n(L) = \mathbb{A}^n(\bar{k})^{G_L}$. For a set $S \subseteq \bar{k}[x_1, \dots, x_n]$ its zero set $V(S) \subseteq \mathbb{A}^n$ is an *algebraic set*; for $Y \subseteq \mathbb{A}^n$, $I(Y)$ is the ideal of polynomials vanishing on Y. The algebraic sets are the closed sets of a topology, the *Zariski topology* (finite unions and arbitrary intersections of algebraic sets are algebraic: $V(S) \cup V(S') = V(SS')$, $\bigcap V(S_i) = V(\bigcup S_i)$). An *affine variety* is an algebraic set V with $I(V)$ prime. It is *defined over* k if $I(V)$ is generated by polynomials in $k[x]$. Its *coordinate ring* is the domain $\bar{k}[V] = \bar{k}[x]/I(V)$, its *function field* $\bar{k}(V) = \mathrm{Frac}\,\bar{k}[V]$; if V is defined over k, $k[V] = k[x]/(I(V) \cap k[x])$ and $k(V) = \mathrm{Frac}\,k[V]$. A function $f \in \bar{k}(V)$ is *regular at* $P \in V$ if $f = g/h$ with $g, h \in \bar{k}[V]$ and $h(P) \neq 0$; then $f(P) = g(P)/h(P)$ does not depend on the choice. The *dimension* of V is the transcendence degree of $\bar{k}(V)$ over $\bar{k}$ ([109, Chapter VIII, Section 1]; Chapter 5 treats algebraic and transcendental elements).

Theorem 8.3 (Hilbert's Nullstellensatz; stated)**.** *For every ideal $\mathfrak{a}$ of $\bar{k}[x_1, \dots, x_n]$, $I(V(\mathfrak{a})) = \sqrt{\mathfrak{a}}$. Hence $V \mapsto I(V)$ is a bijection from algebraic sets to radical ideals, under which affine varieties correspond to prime ideals and points to maximal ideals. For k perfect, an affine variety V is defined over k iff $\sigma(V) = V$ for all $\sigma \in G_k$.*

We do not prove this; see [72, Chapter 1] and [79, Chapter I, Section 1] for the Nullstellensatz, and [185, Chapter I, Section 1] with its exercises for the Galois criterion. Examples: $\mathbb{A}^1$, with $\bar{k}[\mathbb{A}^1] = \bar{k}[x]$; the parabola $y = x^2$, with $\bar{k}[V] = \bar{k}[x, y]/(y - x^2) \simeq \bar{k}[x]$ and $\dim V = 1$; the affine Weierstrass cubics of Example 8.10.

Why points over $\bar{k}$ and not over k? Over a field that is not algebraically closed a polynomial can have too few zeros to be recovered from them ($x^2 + y^2 + 1$ has no zero in $\mathbb{R}^2$, and neither

has 1), so the dictionary between ideals and zero sets of the Nullstellensatz fails; over $\bar{k}$ it holds, and the arithmetic over k is then recorded by the action of G_k. Two small examples over $k=\mathbb{Q}$ show how the definitions interact. The set $V(x^2-2)\subseteq\mathbb{A}^1$ is $\{\sqrt{2},-\sqrt{2}\}$; its ideal $(x^2-2)\bar{k}[x]=(x-\sqrt{2})(x+\sqrt{2})\bar{k}[x]$ is not prime, so it is an algebraic set but not a variety, although x^2-2 is irreducible over $\mathbb{Q}$. Each of its two points is a variety, $V(x\mp\sqrt{2})$, but neither is defined over $\mathbb{Q}$, and indeed $\sigma(\sqrt{2})=-\sqrt{2}$ for some $\sigma\in G_{\mathbb{Q}}$, so the Galois criterion of the theorem fails for each point while the union is $G_{\mathbb{Q}}$-stable. In the same way $V(x^2+1)\subseteq\mathbb{A}^2$ is the union of the two lines $x=\pm i$, exchanged by complex conjugation: the polynomial x^2+1 is irreducible over $\mathbb{Q}$ but not over $\bar{\mathbb{Q}}$. This is why "variety" means "irreducible over $\bar{k}$" in this chapter (Convention 8.1(C2)).

Definition 8.4 (projective space and projective varieties)**.** $\mathbb{P}^n=\mathbb{P}^n(\bar{k})=(\bar{k}^{n+1}\setminus\{0\})/\bar{k}^\times$, with homogeneous coordinates $[x_0:\cdots:x_n]$; for $n=1$ this is the set of lines of Chapter 1, on which PGL_2 acts by Moebius transformations. G_k acts coordinatewise, and $\mathbb{P}^n(L)$ is the set of points with a representative in L^{n+1}. An ideal of $\bar{k}[x_0,\dots,x_n]$ is *homogeneous* if it is generated by homogeneous polynomials; for a set S of homogeneous polynomials $V(S)\subseteq\mathbb{P}^n$ is well defined (whether $F(x)=0$ does not depend on the representative x) and is a *projective algebraic set*; a *projective variety* is a projective algebraic set whose homogeneous ideal $I(V)$ is prime, *defined over k* if $I(V)$ is generated by polynomials with coefficients in k. The sets $U_i=\{x_i\neq 0\}$ are the standard charts, $U_i\simeq\mathbb{A}^n$ by dividing by x_i. The *projective closure* $\bar{V}$ of an affine variety $V\subseteq\mathbb{A}^n=U_0$ is the zero set of the homogenisations of the elements of $I(V)$; conversely $V\cap U_i$ is obtained by dehomogenising. The *function field* $\bar{k}(V)$ of a projective variety is the field of quotients F/G of homogeneous polynomials of the same degree with $G\notin I(V)$, two quotients being equal when $FG'-F'G\in I(V)$; such an f is *regular at $P\in V$* if $f=F/G$ with $G(P)\neq 0$, and then $f(P)=F(P)/G(P)$.

Proposition 8.5 (points over subfields)**.** *Let $k\subseteq L\subseteq\bar{k}$.*

(i) $\mathbb{P}^n(\bar{k})^{G_L}=\mathbb{P}^n(L)$.

(ii) $\mathbb{P}^n=\mathbb{A}^n\sqcup\mathbb{P}^{n-1}$ *(the chart U_0 and the hyperplane $x_0=0$); in particular* $\mathbb{P}^1=\mathbb{A}^1\sqcup\{\infty\}$.

(iii) For a projective variety V meeting U_i, the map $F/G\mapsto(F/G)(x_0,\dots,1,\dots,x_n)$ (the 1 in position i) is an isomorphism of $\bar{k}(V)$ onto the function field of the affine variety $V\cap U_i$; for $P\in V\cap U_i$, a function is regular at P on V iff its image is regular at P on $V\cap U_i$, with the same value.

Proof. (i) A point with a representative in L^{n+1} is fixed by G_L. Conversely let $P=[x_0:\cdots:x_n]$ be fixed by G_L; choose i with $x_i\neq 0$ and scale so that $x_i=1$. For $\sigma\in G_L$, $\sigma P=P$ means $\sigma(x_j)=cx_j$ for all j with one $c\in\bar{k}^\times$; the coordinate $j=i$ gives $c=1$. So every x_j is fixed by G_L, hence lies in L ($\bar{k}^{G_L}=L$ by Galois theory, Chapter 5, k being perfect). (ii) A point $[x_0:\cdots:x_n]$ either has $x_0\neq 0$, and then it has exactly one representative with $x_0=1$, namely $(1,x_1/x_0,\dots,x_n/x_0)$, which identifies U_0 with $\mathbb{A}^n$; or it has $x_0=0$, and then $[x_1:\cdots:x_n]$ is a well-defined point of $\mathbb{P}^{n-1}$ (not all x_j vanish, and scaling acts on both sides in the same way). For $n=1$ the second set is the single point $[0:1]$, which is called ∞. (iii) A quotient F/G of forms of degree d equals $(F/x_i^d)/(G/x_i^d)$, a quotient of polynomials in the affine coordinates x_j/x_i; conversely a quotient of polynomials in the affine coordinates is homogenised by multiplying numerator and denominator by a power of x_i. The two constructions are inverse, and both respect the ideals. If $G(P)\neq 0$ then $(G/x_i^d)(P)\neq 0$, as $x_i(P)\neq 0$; conversely, if $f=g/h$ with

$h(P) \neq 0$ on $V \cap U_i$, homogenising g and h to forms F, G of the same degree d (multiplying the one of lower degree by a power of x_i) gives $f = F/G$ with $G(P) = x_i(P)^d h(P) \neq 0$. The values agree, since both are computed from the same representative of P with $x_i = 1$. □

Definition 8.6 (curves, rational maps, morphisms)**.** A *curve over k* is a projective variety of dimension one defined over k (Convention 8.1). Let V_1, $V_2 \subseteq \mathbb{P}^n$ be projective varieties. A *rational map* $\varphi = [f_0 : \cdots : f_n] \colon V_1 \dashrightarrow V_2$ is given by $f_i \in \bar{k}(V_1)$, not all zero, such that $\varphi(P) = [f_0(P) : \cdots : f_n(P)] \in V_2$ wherever all f_i are defined and not all zero; $[f_0 : \cdots : f_n]$ and $[gf_0 : \cdots : gf_n]$ define the same map for $g \in \bar{k}(V_1)^\times$. It is *regular* at P if there is g with all gf_i regular at P and some $(gf_i)(P) \neq 0$; a *morphism* is a rational map regular at every point; an *isomorphism* is a morphism with an inverse morphism. φ is *defined over k* if it can be written with all $f_i \in k(V_1)$; for k perfect this holds iff $\varphi(\sigma P) = \sigma(\varphi(P))$ for all $\sigma \in G_k$ and all P ([185, Chapter I, Section 3]; stated).

Example 8.7 (a conic is a line)**.** The map $\psi = [s^2 : st : t^2] \colon \mathbb{P}^1 \to \mathbb{P}^2$ is a morphism onto the conic $C \colon XZ = Y^2$, defined over every k. Its inverse is $[X : Y] = [Y : Z]$, a rational map on C that is regular everywhere: at points with $X \neq 0$ use $[X : Y]$, at points with $Z \neq 0$ use $[Y : Z]$; the two agree on C because $XZ = Y^2$, and $X = Z = 0$ forces $Y = 0$, which is not a point. So $C \simeq \mathbb{P}^1$ over k.

8.2 Plane curves and smoothness

The curves of the paper are given by equations: the elliptic curves by Weierstrass equations (the Appendix of the paper calls `ellinit([1,1,1,-30,-76])`), and $X_0(N)$ by the analytic construction of Chapter 12, whose smooth projective model is the curve of Theorem 8.49. This section says when an equation defines a smooth curve and proves the local fact behind every order of a zero or a pole in the rest of the book: at a smooth point the local ring is a discrete valuation ring (Theorem 8.11). Bezout's theorem is stated for the degree of the divisor of a linear form.

Definition 8.8 (plane curves; singular points)**.** A *plane curve of degree d* is $C = V(F) \subseteq \mathbb{P}^2$ for a homogeneous $F \in k[X, Y, Z]$ of degree d that is irreducible in $\bar{k}[X, Y, Z]$; its affine part is $f(x, y) = F(x, y, 1) = 0$. A point $P \in C(\bar{k})$ is *singular* if $F_X(P) = F_Y(P) = F_Z(P) = 0$ (subscripts are partial derivatives) and *smooth* otherwise; C is *smooth* if it has no singular point in $C(\bar{k})$. For a general variety $V \subseteq \mathbb{P}^n$ with $I(V) = (F_1, \ldots, F_m)$ of dimension one, P is smooth if the Jacobian matrix $(\partial F_i / \partial x_j(P))$ has rank $n - 1$ [185, Chapter I, Section 1].

Proposition 8.9 (the affine criterion; tangent lines)**.** *Let $C = V(F)$ be a plane curve of degree d.*

(i) (Euler) $XF_X + YF_Y + ZF_Z = dF$. Hence a point $P = (a, b)$ of the affine part is singular iff $f(P) = f_x(P) = f_y(P) = 0$; and if $\operatorname{char} k \nmid d$, every common zero in $\mathbb{P}^2$ of F_X, F_Y, F_Z lies on C.

(ii) At a smooth point P the tangent line *is $F_X(P)X + F_Y(P)Y + F_Z(P)Z = 0$; on the affine part it is $f_x(P)(x - a) + f_y(P)(y - b) = 0$.*

Proof. (i) Both sides of Euler's identity are additive in F, and for a monomial $X^i Y^j Z^m$ with $i + j + m = d$ the left side is $(i + j + m)X^i Y^j Z^m$. On the affine part $f_x(a, b) = F_X(a, b, 1)$ and

$f_y(a,b) = F_Y(a,b,1)$, and at a point of C, Euler gives $F_Z(a,b,1) = -aF_X(a,b,1) - bF_Y(a,b,1)$; so the three partials vanish iff f_x and f_y do. If $\operatorname{char} k \nmid d$ and the three partials vanish at P, Euler gives $dF(P) = 0$, so $F(P) = 0$. (ii) The projective equation is a definition. On the affine part put $Z = 1$, $X = x$, $Y = y$ and $P = (a,b,1)$; using $F_Z(P) = -af_x(P) - bf_y(P)$ from (i), the projective equation becomes

$$f_x(P)x + f_y(P)y - af_x(P) - bf_y(P) = f_x(P)(x-a) + f_y(P)(y-b) = 0,$$

the affine tangent line of calculus. □

So for an affine equation one never needs the homogenisation away from infinity: smoothness at (a,b) is the familiar condition that the gradient (f_x, f_y) does not vanish there, and (in the real picture) the tangent line is orthogonal to that gradient. Only the points at infinity require the projective partials, and Example 8.10 shows how they are handled.

Example 8.10 (the paper's curves are smooth; the node and the cusp are not)**.**

(a) The *nodal cubic* $y^2 = x^3 + x^2$ and the *cuspidal cubic* $y^2 = x^3$ have the single singular point $(0,0)$: for $f = y^2 - x^3 - x^2$, $f_y = 2y$ and $f_x = -3x^2 - 2x$ vanish together on the curve only at $(0,0)$ when $\operatorname{char} k \neq 2$ (at $x = -1$, $f_x = -1$), and at infinity ($[0:1:0]$, where $F_Z = Y^2 - X^2 \neq 0$) the curve is smooth; likewise for $y^2 = x^3$. Over $\mathbb{R}$ the node is a loop crossing itself at the origin with two tangent lines $y = \pm x$, and the cusp is a curve with a sharp point at the origin with the single tangent $y = 0$ counted twice.

(b) The *Fermat curve* $X^d + Y^d + Z^d = 0$ is smooth iff $\operatorname{char} k \nmid d$. If $\operatorname{char} k \nmid d$, the partials dX^{d-1}, dY^{d-1}, dZ^{d-1} vanish together only at $X = Y = Z = 0$. If $d = p = \operatorname{char} k$ the polynomial is $(X+Y+Z)^p$, which is not even irreducible; for $p \mid d$ in general all partials vanish identically.

(c) The Weierstrass cubics

$$\texttt{11a1}\colon y^2 + y = x^3 - x^2 - 10x - 20, \qquad \texttt{20a1}\colon y^2 = x^3 + x^2 + 4x + 4,$$
$$\texttt{121a1}\colon y^2 + xy + y = x^3 + x^2 - 30x - 76$$

are smooth over $\bar{\mathbb{Q}}$, including the point $[0:1:0]$ at infinity. At infinity: for $F = Y^2Z + a_1XYZ + a_3YZ^2 - X^3 - a_2X^2Z - a_4XZ^2 - a_6Z^3$ one has $F_Z(0,1,0) = 1$, so $[0:1:0]$ is always smooth. On the affine part of `11a1`, $f_y = 2y+1$ and $f_x = -3x^2+2x+10$; a singular point would have $y = -\frac{1}{2}$ and then x would be a double root of $4x^3 - 4x^2 - 40x - 79$, whose discriminant is $-2^4 \cdot 11^5 \neq 0$ (computed with PARI). The general criterion (a Weierstrass cubic is smooth iff its discriminant Δ is nonzero; $\Delta = -11^5$ for `11a1`, $-2^8 \cdot 5^2$ for `20a1`, -11^2 for `121a1`) is proved in Chapter 9.

Theorem 8.11 (smooth points and discrete valuation rings)**.** *Let C be a curve, $P \in C(\bar{k})$, $\bar{k}[C]_P = \{f \in \bar{k}(C) : f$ regular at $P\}$ (Definition 8.4) its local ring and $\mathfrak{m}_P$ the maximal ideal of functions vanishing at P. The following are equivalent: (a) P is smooth; (b) $\dim_{\bar{k}} \mathfrak{m}_P/\mathfrak{m}_P^2 = 1$; (c) $\bar{k}[C]_P$ is a discrete valuation ring. At a smooth point $P = (a,b)$ of an affine plane model $f = 0$, the class of a linear form $\lambda = u(x-a) + v(y-b)$ is a uniformiser iff the line $\lambda = 0$ is not the tangent line; for instance $x - a$ is a uniformiser if $f_y(P) \neq 0$. The valuation* $\operatorname{ord}_P\colon \bar{k}(C)^\times \to \mathbb{Z}$ *of $\bar{k}[C]_P$ is the* order of vanishing *at P, and $g \in \bar{k}(C)$ is regular at P iff $g = 0$ or $\operatorname{ord}_P g \geq 0$.*

Proof. We prove the theorem for a point of an affine plane model $f(x,y)=0$, f irreducible; for a point of a curve in $\mathbb{P}^n$ the same argument with the Jacobian matrix gives the general case [185, Chapter II, Proposition 1.1]. Translate so that $P=(0,0)$. Let $A=\bar{k}[x,y]$, $\mathfrak{M}=(x,y)$, $R=\bar{k}[C]=A/(f)$ and $\mathfrak{m}=\mathfrak{M}/(f)$. The local ring $\bar{k}[C]_P$ is the localisation $R_{\mathfrak{m}}$ (Chapter 3; regularity may be tested on an affine chart by Proposition 8.5(iii)), with maximal ideal $\mathfrak{m}_P=\mathfrak{m}R_{\mathfrak{m}}$. Since $\mathfrak{m}/\mathfrak{m}^2$ is killed by $\mathfrak{m}$, it is a vector space over $R/\mathfrak{m}=\bar{k}$, and an element $s\in R\setminus\mathfrak{m}$ acts on it as the nonzero scalar $s(P)$ (because $s-s(P)\in\mathfrak{m}$), hence invertibly. So inverting the elements of $R\setminus\mathfrak{m}$ changes nothing: $\mathfrak{m}_P/\mathfrak{m}_P^2=\mathfrak{m}/\mathfrak{m}^2=\mathfrak{M}/(\mathfrak{M}^2+(f))$. Now $\mathfrak{M}/\mathfrak{M}^2$ is the two-dimensional space with basis the classes of x, y, and by Taylor's formula $f\equiv f_x(P)x+f_y(P)y \pmod{\mathfrak{M}^2}$ (as $f(P)=0$). So $\mathfrak{m}_P/\mathfrak{m}_P^2$ is the quotient of $\bar{k}x\oplus\bar{k}y$ by the span of $f_x(P)x+f_y(P)y$: of dimension 1 if P is smooth and 2 if not (Proposition 8.9(i)). This proves (a)$\Leftrightarrow$(b) and shows that a linear form is nonzero in $\mathfrak{m}_P/\mathfrak{m}_P^2$ iff it is not proportional to the tangent form.

The ring $\bar{k}[C]_P$ is a Noetherian local domain (a localisation of a quotient of the Noetherian ring A), and not a field: C has dimension one, so x and y are not both constant on C, and a nonconstant one of them is a nonzero element of $\mathfrak{m}_P$. (b)$\Rightarrow$(c): if $t\in\mathfrak{m}_P$ spans $\mathfrak{m}_P/\mathfrak{m}_P^2$, then $\mathfrak{m}_P=t\bar{k}[C]_P+\mathfrak{m}_P^2$, and Nakayama's lemma (Chapter 3) gives $\mathfrak{m}_P=(t)$; a Noetherian local domain that is not a field and has principal maximal ideal is a discrete valuation ring with uniformiser t (the criterion of Chapter 3). (c)$\Rightarrow$(b): if $\mathfrak{m}_P=(t)$ then $\mathfrak{m}_P/\mathfrak{m}_P^2$ is spanned by the class of t, and it is nonzero because $\mathfrak{m}_P\neq\mathfrak{m}_P^2$ by Nakayama. The last sentence is the description of a discrete valuation ring by its valuation (Chapter 3). □

Two computations show the theorem at work. On the smooth cubic $y^2=h(x)$, h squarefree of degree 3, $\operatorname{char}k\neq 2$, take a root e of h and $P=(e,0)$. There $f_y=2y$ vanishes and $f_x=-h'(e)\neq 0$, so the tangent line is the vertical line $x=e$, and $x-e$ is *not* a uniformiser; y is one. Indeed $x-e=y^2/q(x)$ with $q(x)=h(x)/(x-e)$, and $q(e)=h'(e)\neq 0$, so $q(x)$ is a unit at P and $\operatorname{ord}_P(x-e)=2$: the vertical tangent meets the curve doubly at P. At the node of $y^2=x^3+x^2$ the computation of the proof gives $\mathfrak{m}_P/\mathfrak{m}_P^2=\bar{k}x\oplus\bar{k}y$ (the gradient vanishes), of dimension two, so the local ring at the node is not a discrete valuation ring and no single order of vanishing can be attached to a function there; the smooth model of Theorem 8.13 replaces the node by two points, each with its own valuation.

Theorem 8.12 (Bezout; stated)**.** *Two plane curves of degrees m and n without a common component meet in exactly mn points of $\mathbb{P}^2(\bar{k})$ counted with intersection multiplicity. In particular a line not contained in a plane curve of degree d meets it in d points counted with multiplicity, and a line meets a cubic in three points (the chord-tangent construction of Chapter 9).*

We do not prove this; see [72, Chapter 5, Section 3] and [79, Chapter I, Section 7]. On a smooth plane curve the intersection multiplicity of the curve with a line $L=0$ at P is $\operatorname{ord}_P(L/M)$ for any linear form M with $M(P)\neq 0$ [72, Chapter 3], so the divisor of zeros of L/M (Definition 8.21) has degree d. For example, on a Weierstrass cubic the line at infinity $Z=0$ meets the curve only at $O=[0:1:0]$ (put $Z=0$ in the equation: $X^3=0$), and in the chart $Y=1$ the function $Z/Y=v$ has $\operatorname{ord}_O v=3$ (computed for $y^2=h(x)$ in the proof of Proposition 8.26(iv)): the line at infinity is a flex tangent, meeting the cubic at O with multiplicity $3=d$, as Bezout requires.

Theorem 8.13 (smooth projective models; stated)**.** *Every curve, possibly singular or affine, is birational over k to a smooth projective curve, which is unique up to isomorphism over k. Its points over $\bar{k}$ correspond bijectively to the discrete valuations of $\bar{k}(C)$ trivial on $\bar{k}$.*

We do not prove this; it follows from Theorem 8.17, see [79, Chapter I, Section 6] and [72, Chapter 7]. Example (proved): the nodal cubic $y^2 = x^3 + x^2$ is birational to $\mathbb{P}^1$ through $t = y/x$, with inverse $x = t^2 - 1$, $y = t(t^2 - 1)$: substituting $y = tx$ in the equation gives $x^2(t^2 - x - 1) = 0$. The two branches through the node correspond to $t = \pm 1$: the smooth model separates them. In the paper a curve given by an equation always means the smooth projective model.

8.3 Function fields, points over extensions, the Galois action

This section turns a curve into its field of rational functions, and back. Its uses in the paper are two. The modular parametrisation $\varphi_E \colon X_0(N) \to E$ is the same thing as the field embedding $\varphi_E^* \colon \mathbb{Q}(E) \to \mathbb{Q}(X_0(N))$ (Theorem 8.17), and its degree is the degree of that field extension (Definition 8.37). And the Galois representation $\rho_{E,\ell}$ of Section 1.1 of the paper, and the action of $G_\mathbb{Q}$ on $E[3]$ in Proposition prop:ns, are the action of G_k on points of Proposition 8.18.

Definition 8.14 (function fields of one variable)**.** A *function field of one variable over k* is a finitely generated field extension F/k of transcendence degree one in which k is algebraically closed. For a curve C over k, $k(C)$ is one, and $\bar{k}(C) = \bar{k} \cdot k(C)$ is one over $\bar{k}$ [185, Chapter II, Section 1].

The examples to keep in mind are $k(\mathbb{P}^1) = k(x)$, and, for a Weierstrass cubic E, $k(E) = k(x)[y]/(y^2 + a_1xy + a_3y - x^3 - a_2x^2 - a_4x - a_6)$, a quadratic extension of $k(x)$. "Transcendence degree one" says that the curve has dimension one. The condition that k be algebraically closed in F excludes, for $k = \mathbb{Q}$, a field such as $\mathbb{Q}(i)(y)$: it is finitely generated of transcendence degree one over $\mathbb{Q}$, and it is the function field over $\mathbb{Q}$ of the plane set $x^2 + 1 = 0$, which over $\bar{\mathbb{Q}}$ falls apart into the two conjugate lines $x = \pm i$ (the second example after Theorem 8.3). A function field of one variable over k is thus the function field of a curve that stays irreducible over $\bar{k}$.

Proposition 8.15 (valuations of a function field)**.** *Let C be a smooth curve.*

(i) Each $P \in C(\bar{k})$ gives a discrete valuation ord_P of $\bar{k}(C)$ with $\operatorname{ord}_P(c) = 0$ for $c \in \bar{k}^\times$.

(ii) For $f \in \bar{k}(C)^\times$, $\operatorname{ord}_P f = 0$ for all but finitely many P.

(iii) A rational function without poles is constant (proved in Corollary 8.39(vi)).

Proof. (i) is Theorem 8.11; a nonzero constant is a unit of every local ring. (ii) Cover C by finitely many affine pieces (the charts U_i). On one piece write $f = g/h$ with g, h regular functions, not zero. Off the zero sets $V(g)$ and $V(h)$ of the piece, f is a unit of the local ring, so $\operatorname{ord}_P f = 0$. The zero set of a nonzero regular function on an irreducible curve is a proper closed subset, hence finite (a proper closed subset of an irreducible variety of dimension one has dimension zero; [79, Chapter I, Section 1], stated). (iii) is proved after Theorem 8.38. □

Theorem 8.16 (rational maps from smooth curves are morphisms)**.** *Let C be a smooth curve, $V \subseteq \mathbb{P}^n$ a projective variety and $\varphi = [f_0 : \cdots : f_n] \colon C \dashrightarrow V$ a rational map. Then φ is a morphism. In particular a rational map between smooth projective curves is a morphism, and every $f \in \bar{k}(C)$ defines a morphism $[f : 1] \colon C \to \mathbb{P}^1$ (constant if f is), with $\infty = [1 : 0]$ the image of the poles.*

Proof. Let $P \in C$, t a uniformiser at P (Theorem 8.11) and $m = \min\{\operatorname{ord}_P f_i : f_i \neq 0\}$. Then each $t^{-m} f_i$ has $\operatorname{ord}_P \geq 0$, so is regular at P, and for an index with $\operatorname{ord}_P f_i = m$ the function $t^{-m} f_i$ is a unit at P, nonzero at P. So $g = t^{-m}$ shows that φ is regular at P. For $f \in \bar{k}(C)$ nonconstant this applies to $[f : 1]$; at a pole $m = \operatorname{ord}_P f < 0$ and $[t^{-m} f : t^{-m}](P) = [1 : 0]$. □

Smoothness of the source is essential. On the nodal cubic $y^2 = x^3 + x^2$ the rational map $t = y/x$ to $\mathbb{P}^1$ is not regular at the node. The parametrisation $\psi(t) = (t^2 - 1, t(t^2 - 1))$ of the example after Theorem 8.13 is a morphism $\mathbb{P}^1 \to C$ (extended to ∞ by this theorem, since $\mathbb{P}^1$ is smooth), and $(y/x) \circ \psi$ is the identity of $\mathbb{P}^1$. If y/x were regular at the node S with some value c, then evaluating $(y/x) \circ \psi$ at $t = 1$ and at $t = -1$, both of which map to S, would give $c = 1$ and $c = -1$. The two branches through the node ask for two different values, which a single point cannot provide; the smooth model has two points there.

Theorem 8.17 (curves and function fields; stated)**.** *The functor $C \mapsto k(C)$, $(\varphi\colon C_1 \to C_2) \mapsto (\varphi^*\colon k(C_2) \to k(C_1),\ f \mapsto f \circ \varphi)$ is a contravariant equivalence between the category of smooth projective curves over k with nonconstant morphisms defined over k, and the category of function fields of one variable over k with k-embeddings. In particular two smooth projective curves with k-isomorphic function fields are isomorphic over k, and a nonconstant morphism of degree one (Definition 8.37) is an isomorphism.*

We do not prove this; see [185, Chapter II, Theorem 2.4] and [79, Chapter I, Corollary 6.12]. The idea: the points of the smooth projective model are the discrete valuations of the function field trivial on the constants (Theorem 8.13), and a field embedding pulls back valuations.

Proposition 8.18 (the Galois action on points and functions)**.** *Let C be a curve over k.*

(i) G_k acts on $C(\bar{k})$, and $C(\bar{k})^{G_L} = C(L)$ for $k \subseteq L \subseteq \bar{k}$.

(ii) G_k acts on $\bar{k}(C)$ through the coefficients: for $f = F/G$, $\sigma f = F^\sigma / G^\sigma$. For f regular at P, σf is regular at σP and $(\sigma f)(\sigma P) = \sigma(f(P))$; for C smooth, $\operatorname{ord}_{\sigma P}(\sigma f) = \operatorname{ord}_P f$. The fixed field of G_k on $\bar{k}(C)$ is $k(C)$ (stated).

(iii) A morphism φ defined over k satisfies $\varphi(\sigma P) = \sigma(\varphi(P))$; hence $\varphi(C_1(L)) \subseteq C_2(L)$, and the fibre $\varphi^{-1}(Q)$ over $Q \in C_2(k)$ is G_k-stable.

Proof. (i) $C(\bar{k})$ is G_k-stable: if $F(P) = 0$ for every F in a set of generators of $I(C)$ with coefficients in k, then $F(\sigma P) = \sigma(F(P)) = 0$. The fixed points are given by Proposition 8.5(i). (ii) F^σ (apply σ to the coefficients) is well defined on $\bar{k}(C)$ because $I(C)$ is generated by polynomials with coefficients in k, so σ maps $I(C) \otimes \bar{k}$ to itself. For $f = F/G$ with $G(P) \neq 0$, $F^\sigma(\sigma P) = \sigma(F(P))$ and $G^\sigma(\sigma P) = \sigma(G(P)) \neq 0$. So $f \mapsto \sigma f$ is a field automorphism of $\bar{k}(C)$ (semilinear over σ) that maps the local ring at P onto the local ring at σP and $\mathfrak{m}_P$ onto $\mathfrak{m}_{\sigma P}$; it therefore maps a uniformiser at P to one at σP and preserves valuations. That the fixed field is $k(C)$ is Hilbert's Theorem 90 for the vector space $\bar{k}(C)$ over $\bar{k}$ [185, Chapter II, Section 5]. (iii) If $\varphi = [f_0 : \cdots : f_n]$ with $f_i \in k(C_1)$, then $\sigma f_i = f_i$, and by (ii) $\sigma(\varphi(P)) = [\sigma f_0(\sigma P) : \ldots] = \varphi(\sigma P)$. If some $g \in \bar{k}(C_1)^\times$ is needed to evaluate at P, that is $\varphi(P) = [(gf_0)(P) : \cdots : (gf_n)(P)]$, then $\sigma(\varphi(P)) = [(\sigma g\, f_0)(\sigma P) : \cdots : (\sigma g\, f_n)(\sigma P)]$, and σg does the same job at σP, so this is $\varphi(\sigma P)$. The rest follows from (i). □

Warning 8.19 (a curve need not have a rational point). The conic $X^2 + Y^2 + Z^2 = 0$ over $\mathbb{Q}$ has no point over $\mathbb{R}$, so $C(\mathbb{Q}) = \emptyset$; but $[1 : i : 0] \in C(\mathbb{Q}(i))$. It is a smooth curve of genus 0 (Example 8.32)

that is isomorphic to $\mathbb{P}^1$ over $\mathbb{Q}(i)$ (project from $[1:i:0]$, as in Corollary 8.30(d)) but not over $\mathbb{Q}$, since an isomorphism over $\mathbb{Q}$ would map $\mathbb{P}^1(\mathbb{Q}) \neq \emptyset$ into $C(\mathbb{Q})$ (Proposition 8.18(iii)). Selmer's cubic $3X^3 + 4Y^3 + 5Z^3 = 0$ is smooth of genus one with no point over $\mathbb{Q}$, although it has points over $\mathbb{R}$ and over every $\mathbb{Q}_p$ (stated; see [185, Chapter X], section not verified). So Theorem 8.33 and Proposition 8.34 assume a rational point, and the paper's curves have one: O on E, and the cusp ∞ on $X_0(N)$.

In the paper 8.20. Section 1.1 of the paper: $\rho_{E,\ell}$ is the action of $G_{\mathbb{Q}}$ on $E[\ell^n] \subseteq E(\overline{\mathbb{Q}})$ of Proposition 8.18(i), extended to $T_\ell E = \varprojlim E[\ell^n]$ (Chapters 9 and 11). This action respects the group law because the group law is given by rational functions with coefficients in $\mathbb{Q}$ (Proposition 8.34). Proposition prop:ns: $G_{\mathbb{Q}}$ acts on the eight points of $E[3]\setminus\{O\}$ and hence on the four roots of the 3-division polynomial, the x-coordinates of those points, by Proposition 8.18(ii), (iii) applied to the function x, which is defined over $\mathbb{Q}$: $x(\sigma P) = \sigma(x(P))$.

8.4 Divisors, differentials, the Picard group

Divisors record zeros and poles; the Picard group is the group of divisors modulo divisors of functions, and its degree-zero part is the Jacobian of Section 8.11. Differentials give the canonical class and, through Riemann-Roch, the genus. In the paper these objects stand behind the group law of E (Proposition 8.34), behind the Jacobian $J_0(N)$ of Remark rem:free, and behind the differential ω_E whose pullback $\varphi_E^*\omega_E = c_E \cdot 2\pi i\, f(z)\, dz$ appears in the proof of Proposition prop:pullback (Chapter 14). Throughout, C is a smooth projective curve over k.

Definition 8.21 (divisors)**.** $\mathrm{Div}(C)$ is the free abelian group on $C(\bar{k})$; its elements are finite sums $D = \sum n_P(P)$. The *degree* is $\deg D = \sum n_P$; $D \geq 0$ (*effective*) means all $n_P \geq 0$; $\mathrm{supp}\, D = \{P : n_P \neq 0\}$. G_k acts by $\sigma D = \sum n_P(\sigma P)$, and $\mathrm{Div}_k(C) = \mathrm{Div}(C)^{G_k}$ is the group of divisors *defined over* k; for instance the sum of the points of a G_k-orbit. The *divisor* of $f \in \bar{k}(C)^\times$ is $\mathrm{div}(f) = \sum_P \mathrm{ord}_P(f)(P)$, a finite sum by Proposition 8.15(ii); its positive and negative parts are the divisors of zeros $\mathrm{div}_0(f)$ and of poles $\mathrm{div}_\infty(f)$. Divisors of functions are *principal*; they form a subgroup $\mathrm{Prin}(C)$, since $\mathrm{div}(fg) = \mathrm{div}(f) + \mathrm{div}(g)$.

Proposition 8.22 (principal divisors)**.** *Let $f \in \bar{k}(C)^\times$.*

(i) $\mathrm{div}(f) = 0$ *iff* $f \in \bar{k}^\times$.

(ii) $\deg \mathrm{div}(f) = 0$*; more precisely, for f nonconstant,* $\deg \mathrm{div}_0(f) = \deg \mathrm{div}_\infty(f) = [\bar{k}(C) : \bar{k}(f)]$.

(iii) $\mathrm{div}(\sigma f) = \sigma\, \mathrm{div}(f)$ *for* $\sigma \in G_k$.

(iv) On $\mathbb{P}^1$ with coordinate x: $\mathrm{div}(x - a) = (a) - (\infty)$*, and* $\mathrm{div}\big(c\prod (x - a_i)^{n_i}\big) = \sum n_i(a_i) - (\sum n_i)(\infty)$.

Proof. (i) If $\mathrm{div}(f) = 0$, f has no pole, so it is constant (Proposition 8.15(iii)); constants have divisor 0. (ii) is Corollary 8.39(vi), which uses the degree formula of Section 8.6; over $\mathbb{C}$ a second proof is Corollary 8.53. (iii) is Proposition 8.18(ii). (iv) At $a \in \bar{k}$ the function $x - a$ is a uniformiser; at ∞ the function $t = 1/x$ is one (in the chart $[1:t]$), and $x - a = t^{-1}(1 - at)$ with $1 - at$ a unit at ∞, so $\mathrm{ord}_\infty(x - a) = -1$. The second formula follows by additivity. □

Example: divisors on a cubic. Let C be the smooth cubic $y^2 = h(x) = (x-e_1)(x-e_2)(x-e_3)$, e_i distinct, $\operatorname{char} k \neq 2$, $O = [0:1:0]$ and $T_i = (e_i, 0)$. The orders needed are computed in the remarks after Theorem 8.11 and in the proof of Proposition 8.26(iv) below: y is a uniformiser at each T_i, $\operatorname{ord}_O y = -3$, $\operatorname{ord}_O x = -2$, and at an affine point with $y \neq 0$ the function $x - a$ is a uniformiser. Hence

$$\operatorname{div}(y) = (T_1) + (T_2) + (T_3) - 3(O), \qquad \operatorname{div}(x - e_1) = 2(T_1) - 2(O),$$
$$\operatorname{div}(x - a) = (P) + (P') - 2(O),$$

the last for a not a root of h, with $P, P' = (a, \pm b)$ and $b^2 = h(a) \neq 0$. All three have degree zero, as Proposition 8.22(ii) requires, and the degrees of the zero divisors, 3 and 2, are the field degrees $[\bar{k}(C) : \bar{k}(y)]$ and $[\bar{k}(C) : \bar{k}(x)]$ (the second because y satisfies a quadratic equation over $\bar{k}(x)$ and is not in $\bar{k}(x)$, h not being a square). Note also $\operatorname{div}(y^2) = 2\operatorname{div}(y) = \sum_i \operatorname{div}(x - e_i)$, as it must be, since $y^2 = \prod(x - e_i)$.

Definition 8.23 (linear equivalence; the Picard group)**.** $D \sim D'$ (*linearly equivalent*) iff $D - D'$ is principal. $\operatorname{Pic}(C) = \operatorname{Div}(C)/\operatorname{Prin}(C)$. By Proposition 8.22(ii) the degree induces $\deg\colon \operatorname{Pic}(C) \to \mathbb{Z}$, with kernel $\operatorname{Pic}^0(C) = \operatorname{Div}^0(C)/\operatorname{Prin}(C)$, Div^0 the divisors of degree zero.

Proposition 8.24 (the Picard group)**.**

(i) $\operatorname{Pic}^0(\mathbb{P}^1) = 0$, *and* $\deg\colon \operatorname{Pic}(\mathbb{P}^1) \to \mathbb{Z}$ *is an isomorphism.*

(ii) G_k *acts on* $\operatorname{Pic}(C)$ *and* $\operatorname{Pic}^0(C)$.

(iii) The natural map $\operatorname{Div}^0_k(C)/\operatorname{div}(k(C)^\times) \to \operatorname{Pic}^0(C)^{G_k}$ *is injective; it is bijective when* $C(k) \neq \emptyset$ *(stated).*

Proof. (i) Every $f \in \bar{k}(\mathbb{P}^1)^\times = \bar{k}(x)^\times$ is $c\prod(x - a_i)^{n_i}$ (factor numerator and denominator over $\bar{k}$), so by Proposition 8.22(iv) a divisor $\sum n_i(a_i) + n_\infty(\infty)$ of degree zero, that is with $n_\infty = -\sum n_i$, is $\operatorname{div}\prod(x - a_i)^{n_i}$. (ii) σ preserves degrees and, by Proposition 8.22(iii), principal divisors. (iii) Let $D \in \operatorname{Div}^0_k(C)$ with $D = \operatorname{div}(f)$ for some $f \in \bar{k}(C)^\times$. Choose a finite Galois extension L/k containing the coefficients of f. For $\sigma \in G_k$, $\operatorname{div}(\sigma f) = \sigma D = D$, so $\sigma f = c_\sigma f$ with $c_\sigma \in \bar{k}^\times$ by Proposition 8.22(i); in fact $c_\sigma \in L^\times$ and c_σ depends only on $\sigma|_L$. Indeed, σf is computed by applying $\sigma|_L$ to the coefficients of f, which lie in L, so it depends only on $\sigma|_L$ and again has coefficients in L (L/k being Galois). So $c_\sigma = \sigma f/f$ is a constant lying in $L(C)$, and the constants in $L(C)$ are the elements of L, since L is algebraically closed in $L(C)$ (Definition 8.14, applied over L). From $\sigma\tau f = \sigma(c_\tau)c_\sigma f$ we get $c_{\sigma\tau} = \sigma(c_\tau)c_\sigma$: a 1-cocycle of $\operatorname{Gal}(L/k)$ with values in $L^\times$. By Hilbert's Theorem 90 (Chapter 5) there is $b \in L^\times$ with $c_\sigma = \sigma(b)/b$; then f/b is fixed by G_k, so lies in $k(C)$ (Proposition 8.18(ii)), and $D = \operatorname{div}(f/b)$. This is injectivity. Surjectivity when $C(k) \neq \emptyset$ uses the vanishing of an obstruction in the Brauer group of k; we do not prove it, see [130, Section 1] (section number not verified) and Chapter 17 for Hilbert 90 in cohomological form. □

Definition 8.25 (differentials)**.** The space Ω_C of (meromorphic) *differentials* is the $\bar{k}(C)$-vector space generated by symbols df, $f \in \bar{k}(C)$, subject to $d(f+g) = df + dg$, $d(fg) = f\,dg + g\,df$ and $da = 0$ for $a \in \bar{k}$. For a uniformiser t at P, every $\omega \in \Omega_C$ is $\omega = g\,dt$ with a unique $g = \omega/dt \in \bar{k}(C)$, and $\operatorname{ord}_P \omega := \operatorname{ord}_P g$. Then $\operatorname{div}(\omega) = \sum_P \operatorname{ord}_P(\omega)(P)$; ω is *regular* (or holomorphic) if $\operatorname{div}(\omega) \geq 0$, and the regular differentials form a $\bar{k}$-vector space.

The definition is the algebraic shadow of the expressions $g(z)\,dz$ of complex analysis: the rules are those of the differential calculus, and ω/dt is "the coefficient of dt" in a local coordinate. Differentials are introduced because, unlike functions, they can be regular everywhere on a projective curve without being constant multiples of each other, and the number of independent regular ones turns out to be the genus (Corollary 8.30(a)). For instance on $\mathbb{P}^1$, $d(x^2) = 2x\,dx$, and at $a \neq 0$ with uniformiser $x - a$, $d(x^2)/d(x-a) = 2x$ has order 0 (if $\operatorname{char} k \neq 2$), while at 0 it has order 1.

Proposition 8.26 (differentials; the canonical class)**.**

(i) Ω_C *is one-dimensional over* $\bar{k}(C)$*, and* df *is a basis iff* $\bar{k}(C)/\bar{k}(f)$ *is a finite separable extension (in characteristic* p*,* $d(f^p) = pf^{p-1}df = 0$*). In particular* dt *is a basis for a uniformiser* t *(stated).*

(ii) $\operatorname{ord}_P \omega$ *does not depend on the uniformiser* t*; if* f *is regular at* P*, so is* df/dt*; and* $\operatorname{ord}_P \omega = 0$ *for all but finitely many* P *(stated).*

(iii) $\operatorname{div}(f\omega) = \operatorname{div}(f) + \operatorname{div}(\omega)$*. Hence the divisors of nonzero differentials form one linear equivalence class, the* canonical class*; any* $\operatorname{div}(\omega)$*,* $\omega \neq 0$*, is a* canonical divisor K_C*.*

(iv) Examples. On $\mathbb{P}^1$*,* $\operatorname{div}(dx) = -2(\infty)$*, so* $\mathbb{P}^1$ *has no nonzero regular differential. On the smooth cubic* $y^2 = h(x)$ *with* h *squarefree of degree* 3 *and* $\operatorname{char} k \neq 2$*,* $\operatorname{div}(dx/y) = 0$*.*

Proof. (i) and (ii) are [185, Chapter II, Propositions 4.2 and 4.3]; we do not prove them. (iii) $f\omega = (fg)\,dt$, and $\operatorname{ord}_P(fg) = \operatorname{ord}_P f + \operatorname{ord}_P g$. If $\omega, \omega' \neq 0$ then $\omega' = f\omega$ for some $f \in \bar{k}(C)^\times$ by (i), so $\operatorname{div}\omega' - \operatorname{div}\omega = \operatorname{div} f$; conversely every divisor linearly equivalent to $\operatorname{div}\omega$ is $\operatorname{div}(f\omega)$.

(iv) On $\mathbb{P}^1$, at $a \in \bar{k}$, $dx = d(x-a)$ has order 0; at ∞, with $t = 1/x$, $dx = d(t^{-1}) = -t^{-2}dt$ has order -2. A regular differential $f\,dx$ would need $\operatorname{div} f \geq 2(\infty)$, of positive degree, impossible by Proposition 8.22(ii) unless $f = 0$.

On $y^2 = h(x)$ let $P = (a, b)$. If $b \neq 0$, then $f_y = 2b \neq 0$, so $x - a$ is a uniformiser (Theorem 8.11), $\operatorname{ord}_P dx = 0$ and y is a unit: $\operatorname{ord}_P(dx/y) = 0$. If $b = 0$, then $h(a) = 0$ and $f_x(P) = -h'(a) \neq 0$ as h is squarefree, so y is a uniformiser; differentiating $y^2 = h(x)$ gives $2y\,dy = h'(x)\,dx$, so $dx = \frac{2y}{h'(x)}dy$ with $h'(x)$ a unit at P: $\operatorname{ord}_P dx = 1$ and $\operatorname{ord}_P(dx/y) = 0$. At the point $O = [0:1:0]$ at infinity (write $h = x^3 + c_2x^2 + c_1x + c_0$ after scaling) use the chart $Y = 1$, with coordinates $u = x/y$, $v = 1/y$; the equation $Y^2Z = X^3 + c_2X^2Z + c_1XZ^2 + c_0Z^3$ becomes $v(1 - c_2u^2 - c_1uv - c_0v^2) = u^3$. Its partial derivative in v at $(0,0)$ is 1, so O is smooth and u is a uniformiser (the tangent line is $v = 0$). The bracket is a unit at O, so $\operatorname{ord}_O v = 3$; hence $\operatorname{ord}_O y = -3$ and $\operatorname{ord}_O x = \operatorname{ord}_O(u/v) = -2$. Write $x = u^{-2}w$ with $w = u^3/v$ a unit, $w(O) = 1$; then $dx = (-2u^{-3}w + u^{-2}w')du$ with $w' = dw/du$ regular (by (ii)), and $-2w + uw'$ takes the value $-2 \neq 0$ at O. So $\operatorname{ord}_O dx = -3$ and $\operatorname{ord}_O(dx/y) = 0$. □

The translation invariance of dx/y, the *invariant differential*, is proved in Chapter 9; for a general Weierstrass equation the differential is $dx/(2y + a_1x + a_3)$, with the same divisor (Example 8.32(b)).

8.5 Riemann-Roch and its consequences

Riemann-Roch is the one deep theorem of the algebraic side; it is stated with a reference and the shape of its proof, and everything after it in this section is proved. Its consequences give the

genus as the number of independent regular differentials, show that a genus-one curve with a rational point is a Weierstrass cubic (Theorem 8.33), and identify such a curve with its own Pic^0 (Proposition 8.34). In the paper these are the facts that an elliptic curve over $\mathbb{Q}$ is given by a Weierstrass equation (as in the Appendix app:repro) and that $E = \mathrm{Pic}^0(E)$ is its own Jacobian, which underlies the factorisation $X_0(N) \to J_0(N) \to E$ used in Proposition prop:pullback.

Definition 8.27 (Riemann-Roch spaces)**.** For $D \in \mathrm{Div}(C)$, $\mathcal{L}(D) = \{f \in \bar{k}(C)^\times : \mathrm{div}(f) + D \geq 0\} \cup \{0\}$, the functions whose poles are bounded by D and which vanish where D requires; $l(D) = \dim_{\bar{k}} \mathcal{L}(D)$.

Proposition 8.28 (Riemann-Roch spaces)**.**

(i) $\mathcal{L}(D)$ *is a* $\bar{k}$*-vector space;* $\mathcal{L}(0) = \bar{k}$*;* $\mathcal{L}(D) = 0$ *if* $\deg D < 0$*; if* $D' = D + \mathrm{div}\, h$ *then* $f \mapsto fh^{-1}$ *is an isomorphism* $\mathcal{L}(D) \to \mathcal{L}(D')$*.*

(ii) $l(D + (P)) \leq l(D) + 1$*. Hence* $l(D) \leq \deg D + 1$ *for* $D \geq 0$*, and* $l(D)$ *is finite for every* D*.*

(iii) $l(D)$ *depends only on the class of* D *in* $\mathrm{Pic}(C)$*; so does* $l(K_C - D)$*.*

(iv) If D *is defined over* k*,* $\mathcal{L}(D)$ *has a basis in* $k(C)$*, and* $\mathcal{L}(D) \cap k(C)$ *is a* k*-space of dimension* $l(D)$ *(stated, except the second clause).*

Proof. (i) If $\mathrm{div}\, f \geq -D$ and $\mathrm{div}\, g \geq -D$, then $\mathrm{ord}_P(f+g) \geq \min(\mathrm{ord}_P f, \mathrm{ord}_P g) \geq -n_P$ for every P; scalars do not change divisors. $\mathcal{L}(0)$ is the space of functions without poles, the constants (Proposition 8.15(iii)). If $f \in \mathcal{L}(D)$, $f \neq 0$, then $\mathrm{div}\, f + D \geq 0$ has degree $\deg D$ (Proposition 8.22(ii)), so $\deg D \geq 0$. Finally $\mathrm{div}(fh^{-1}) + D' = \mathrm{div}\, f + D$.

(ii) Let n be the coefficient of P in D and t a uniformiser at P. For $f \in \mathcal{L}(D + (P))$, $\mathrm{ord}_P f \geq -n-1$, so $t^{n+1}f$ is regular at P, and $\lambda(f) = (t^{n+1}f)(P)$ is a linear map $\mathcal{L}(D+(P)) \to \bar{k}$. Its kernel is $\{f : \mathrm{ord}_P f \geq -n\} = \mathcal{L}(D)$. So $l(D+(P)) \leq l(D)+1$. For $D \geq 0$ add the points one at a time starting from $l(0) = 1$. For general D, $\mathcal{L}(D) \subseteq \mathcal{L}(D^+)$, where D^+ keeps the positive coefficients.

(iii) is (i), applied to D and to $K_C - D$. (iv) The first clause is [185, Chapter II, Proposition 5.8] (Hilbert 90 for vector spaces). Given a basis $f_1, \dots, f_m$ in $k(C)$, if $f = \sum c_i f_i \in k(C)$ then $\sigma f = f$ gives $\sum(\sigma c_i - c_i) f_i = 0$, so $c_i \in k$: the k-span of the f_i is $\mathcal{L}(D) \cap k(C)$. □

Theorem 8.29 (Riemann-Roch; stated)**.** *Let* C *be a smooth projective curve over* k *and* K_C *a canonical divisor. There is an integer* $g \geq 0$*, the* genus *of* C*, such that for every* $D \in \mathrm{Div}(C)$

$$l(D) - l(K_C - D) = \deg D - g + 1.$$

We do not prove this; see [185, Chapter II, Theorem 5.4], which refers the proof to Hartshorne and Lang, [79, Chapter IV, Theorem 1.3], [72, Chapter 8] and [136, Chapter VI] (chapter numbers of Miranda not verified). *Shape of the proof.* By Proposition 8.28(ii), $\deg D + 1 - l(D)$ is bounded above as D grows (one compares $\mathcal{L}(D)$ with $\mathcal{L}(D + n(P))$ and uses a function with a single pole); the maximum of this defect is the genus, which gives Riemann's inequality $l(D) \geq \deg D + 1 - g$. The correction term $l(K_C - D)$ is the dimension of the space of obstructions to finding a function with prescribed principal parts bounded by D (the algebraic Mittag-Leffler problem, in the language of repartitions), and residues of differentials make that space dual to $\mathcal{L}(K_C - D)$; this duality is Serre duality. Over $\mathbb{C}$ the obstruction space is the sheaf cohomology group $H^1(X, \mathcal{O}(D))$, the only appearance of sheaf cohomology in the book; it is never used in a proof.

Corollary 8.30 (consequences of Riemann-Roch)**.** *Let C have genus g.*

(a) $l(K_C) = g$*: the genus is the dimension of the space of regular differentials.*

(b) $\deg K_C = 2g - 2$*.*

(c) If $\deg D > 2g - 2$ *then* $l(D) = \deg D - g + 1$*.*

(d) $g(\mathbb{P}^1) = 0$*. Conversely, a curve C of genus 0 with a point $P \in C(k)$ is isomorphic over k to $\mathbb{P}^1$. A curve with two distinct points P, Q such that $(P) \sim (Q)$ has genus 0.*

(e) If $g = 1$*:* $l(D) = \deg D$ *whenever* $\deg D \geq 1$*;* $K_C \sim 0$*; and a nonzero regular differential has no zeros.*

Proof. (a) Take $D = 0$: $1 - l(K_C) = 1 - g$. The map $f \mapsto f\omega$ identifies $\mathcal{L}(\operatorname{div}\omega)$ with the regular differentials, because $\operatorname{div}(f\omega) = \operatorname{div} f + \operatorname{div}\omega$ (Proposition 8.26(iii)) and every differential is $f\omega$. (b) Take $D = K_C$: $g - 1 = \deg K_C - g + 1$. (c) $\deg(K_C - D) < 0$, so $l(K_C - D) = 0$ by Proposition 8.28(i).

(d) $\deg \operatorname{div}(dx) = -2$ on $\mathbb{P}^1$ (Proposition 8.26(iv)), so $2g - 2 = -2$ by (b). Let $g(C) = 0$ and $P \in C(k)$. By (c), $l((P)) = 1 - 0 + 1 = 2$, and by Proposition 8.28(iv) there is a nonconstant $f \in \mathcal{L}((P)) \cap k(C)$. Its divisor of poles is at most (P) and is nonzero (Proposition 8.15(iii)), so it is exactly (P). By Proposition 8.22(ii) the morphism $f\colon C \to \mathbb{P}^1$, defined over k, has degree $[\bar{k}(C) : \bar{k}(f)] = \deg \operatorname{div}_\infty f = 1$, so it is an isomorphism (Theorem 8.17). If $(P) - (Q) = \operatorname{div} f$ with $P \neq Q$, the same argument applies to f, whose divisor of poles is (Q): $C \simeq \mathbb{P}^1$ over $\bar{k}$, and the genus, defined through l and degrees, is invariant under isomorphism, so $g = 0$.

(e) By (b), $\deg K_C = 0$, so (c) gives $l(D) = \deg D$ for $\deg D \geq 1$. By (a), $l(K_C) = 1$: there is $f \neq 0$ with $\operatorname{div} f + K_C \geq 0$; this effective divisor has degree 0, so it is 0, and $K_C \sim 0$. If ω is regular and nonzero, $\operatorname{div}\omega$ is effective of degree 0, hence 0. □

Theorem 8.31 (genus of a smooth plane curve)**.** *A smooth plane curve of degree d over k, in any characteristic, has genus*

$$g = \frac{(d-1)(d-2)}{2}.$$

Sketch of proof. Choose coordinates in general position: so that f_y is not identically zero, the line at infinity $Z = 0$ is tangent to C nowhere (so it meets C in d distinct points, by Theorem 8.12), and $[0 : 1 : 0] \notin C$. On the affine part $f(x, y) = 0$ put $\omega_0 = dx/f_y = -dy/f_x$ (the two agree because $f_x\,dx + f_y\,dy = d(f) = 0$ on C). At an affine point with $f_y \neq 0$, $x - a$ is a uniformiser and $\operatorname{ord}\omega_0 = 0$; at an affine point with $f_y = 0$, $f_x \neq 0$ by smoothness, $y - b$ is a uniformiser and $\operatorname{ord}\omega_0 = \operatorname{ord}(-dy/f_x) = 0$. So ω_0 is regular and nowhere zero on the affine part. At infinity we compute in a chart, as in Proposition 8.26(iv). Since $[0 : 1 : 0] \notin C$, every point P of C on the line $Z = 0$ has $X \neq 0$, so it lies in the chart $X = 1$, with affine coordinates $u = Y/X$, $v = Z/X$ and equation $g(u, v) = F(1, u, v) = 0$. In these coordinates $x = X/Z = 1/v$ and $y = Y/Z = u/v$. The line $Z = 0$ is $v = 0$; it is not the tangent at P, so $g_u(P) \neq 0$ (the tangent is $g_u(P)(u - u(P)) + g_v(P)v = 0$, Proposition 8.9(ii)), and v is a uniformiser at P (Theorem 8.11). Now F_Y is homogeneous of degree $d - 1$, so

$$f_y = F_Y(x, y, 1) = F_Y(v^{-1}, uv^{-1}, 1) = v^{1-d}F_Y(1, u, v) = v^{1-d}g_u(u, v),$$

and g_u is a unit at P: $\operatorname{ord}_P f_y = 1 - d$. Also $dx = d(v^{-1}) = -v^{-2}dv$ has order -2. Hence $\operatorname{ord}_P \omega_0 = -2 - (1 - d) = d - 3$ at each of the d points at infinity. As Z/M (for a linear form M

not vanishing at these points) has a simple zero at each of them and no other zero, this reads $\operatorname{div}(\omega_0) = (d-3)\cdot\operatorname{div}_0(Z/M)$, a divisor of degree $d(d-3)$ (Theorem 8.12). By Corollary 8.30(b), $2g-2 = d(d-3)$, so $g = \frac{d^2-3d+2}{2} = \frac{(d-1)(d-2)}{2}$. For $d=3$ the form ω_0 has no zeros or poles at all, as for $dx/(2y+a_1x+a_3)$ on a Weierstrass cubic. One also finds that the regular differentials are exactly the $h(x,y)\,\omega_0$ with $\deg h \le d-3$, a space of dimension $\binom{d-1}{2}$, in agreement with Corollary 8.30(a). See [72, Chapter 8] and [79, Chapter IV, Section 1, and Chapter I, Section 7] (sections not verified). The argument needs no hypothesis on the characteristic, because such coordinates always exist: the tangent lines of C form at most a one-dimensional family in the two-dimensional family of lines, so a general line is tangent nowhere; and F_X, F_Y, F_Z are not all identically zero (C being smooth), so after a general linear change of coordinates F_Y, hence f_y, is not identically zero (in characteristic p this can fail for special coordinates, when $f \in k[x,y^p]$). □

Example 8.32 (genera)**.**

(a) Lines and smooth conics have genus 0 (Theorem 8.31 with $d = 1, 2$; for the conic, also Example 8.7).

(b) Smooth plane cubics have genus 1; in particular every smooth Weierstrass cubic, such as `11a1`, `20a1`, `121a1`. If $\operatorname{char} k \neq 2$ the substitution $y \mapsto y - \frac{1}{2}(a_1x+a_3)$ turns $y^2 + a_1xy + a_3y = x^3 + \dots$ into $y^2 = h(x)$ and $dx/(2y+a_1x+a_3)$ into $\frac{1}{2}dx/y$; so the differential $\omega = dx/(2y+a_1x+a_3)$ has divisor 0 by Proposition 8.26(iv) (smoothness makes h squarefree), and is regular and nowhere zero. This gives $g = 1$ again, from Corollary 8.30(b).

(c) The Fermat quartic $X^4 + Y^4 + Z^4 = 0$ has genus 3 ($\operatorname{char} k \neq 2$): it is smooth by Example 8.10(b), and $\frac{(4-1)(4-2)}{2} = 3$.

(d) Hyperelliptic curves: the smooth projective model of $y^2 = h(x)$, h squarefree of degree $2g+1$ or $2g+2$, $\operatorname{char} k \neq 2$, has genus g (Corollary 8.45(c)); for instance $y^2 = x^5 - x$ has genus 2, since $x^5 - x = x(x-1)(x+1)(x^2+1)$ has degree $5 = 2\cdot 2 + 1$ and discriminant -2^8, nonzero for $\operatorname{char} k \neq 2$. For $g \ge 2$ the projective closure in $\mathbb{P}^2$ is singular at infinity, so Theorem 8.31 does not apply directly. Indeed, for $\deg h = n \ge 4$ the homogenised equation $Y^2Z^{n-2} = Z^n h(X/Z)$ meets $Z = 0$ only at $[0:1:0]$, and in the chart $Y = 1$ it reads $Z^{n-2} = (\text{leading coefficient})X^n + (\text{terms divisible by } Z)$, whose lowest-degree part at the origin has degree $\min(n-2, n) = n-2 \ge 2$: all partial derivatives vanish there. Were the plane formula applicable it would give $\frac{(n-1)(n-2)}{2}$, which for $n = 5$ is 6, not 2.

(e) Singular plane models have smaller genus: the nodal and cuspidal cubics are rational (Theorem 8.13 and Example 8.10). In general $g = \frac{(d-1)(d-2)}{2} - \sum_P \delta_P$, with a positive local invariant δ_P at each singular point (stated; [72, Chapter 7], [79, Chapter IV, Section 1], sections not verified).

(f) The modular curves are not given as smooth plane curves; their genera come from Riemann-Hurwitz (Corollary 8.45(f) and Chapter 12): $g(X_0(11)) = g(X_0(20)) = 1$, $g(X_0(121)) = 6$, $g(X_0(539)) = 49$. We computed these from the genus formula of Chapter 12 and checked them with PARI's `mfdim([N,2],1)`, which is $\dim S_2(\Gamma_0(N)) = g(X_0(N))$ (Theorem 8.54).

Theorem 8.33 (a genus-one curve with a rational point is a Weierstrass cubic)**.** *Let C be a smooth projective curve of genus one over k and $O \in C(k)$.*

(i) *There are* $x \in \mathcal{L}(2(O))$ *and* $y \in \mathcal{L}(3(O))$, *in* $k(C)$, *with* $\mathcal{L}(2(O)) = \langle 1, x\rangle$, $\mathcal{L}(3(O)) = \langle 1, x, y\rangle$, $\operatorname{ord}_O x = -2$, $\operatorname{ord}_O y = -3$.

(ii) *After rescaling* x *and* y *by elements of* $k^\times$ *they satisfy a Weierstrass equation*

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6, \qquad a_i \in k.$$

(iii) *The morphism* $\varphi = [x : y : 1]\colon C \to \mathbb{P}^2$ *is an isomorphism onto the projective cubic* E *defined by this equation,* E *is smooth, and* $\varphi(O) = [0 : 1 : 0]$.

(iv) *Conversely, a smooth Weierstrass cubic has genus one, and* $[0 : 1 : 0]$ *is a point of it defined over* k.

Proof. (i) By Corollary 8.30(e), $l(n(O)) = n$ for $n \geq 1$; so $\mathcal{L}((O)) = \bar{k}$ and each step $\mathcal{L}((n-1)(O)) \subset \mathcal{L}(n(O))$, $n \geq 2$, adds exactly one dimension, that is, a function with a pole of order exactly n at O and no other pole. By Proposition 8.28(iv) the k-rational parts $\mathcal{L}(n(O)) \cap k(C)$ have k-dimension n, so we can choose $x \in \mathcal{L}(2(O)) \cap k(C)$ not in $\mathcal{L}((O))$ and $y \in \mathcal{L}(3(O)) \cap k(C)$ not in $\mathcal{L}(2(O))$.

(ii) The seven functions $1, x, y, x^2, xy, y^2, x^3$ have poles at O only, of orders $0, 2, 3, 4, 5, 6, 6$, so they lie in $\mathcal{L}(6(O)) \cap k(C)$, a k-space of dimension 6. They are linearly dependent over k. In a nontrivial relation the coefficients A of y^2 and B of x^3 are both nonzero: if one of them were zero, the other term would be the only one with a pole of order 6, so its coefficient would vanish too, and then $1, x, y, x^2, xy$, which have distinct pole orders, would be linearly independent, forcing all coefficients to be zero. Write the relation as $Ay^2 + b_1xy + b_3y = Bx^3 + b_2x^2 + b_4x + b_6$ and substitute $x = ABx'$, $y = AB^2y'$. Then $Ay^2 = A^3B^4y'^2$ and $Bx^3 = A^3B^4x'^3$, so after dividing by A^3B^4 both leading terms have coefficient 1, and the relation becomes

$$y'^2 + \frac{b_1}{AB}x'y' + \frac{b_3}{A^2B^2}y' = x'^3 + \frac{b_2}{AB^2}x'^2 + \frac{b_4}{A^2B^3}x' + \frac{b_6}{A^3B^4},$$

a Weierstrass equation with coefficients in k. The new functions x', y' still have poles of orders exactly 2 and 3 at O and no other pole, so (i) holds for them; we rename them x, y. (A scaling $x = \alpha x'$, $y = \beta y'$ makes both leading coefficients equal exactly when $A\beta^2 = B\alpha^3$; the choice $\alpha = AB$, $\beta = AB^2$ is one solution with $\alpha, \beta \in k^\times$.)

(iii) φ is a morphism (Theorem 8.16) defined over k, with image in E. Writing $\varphi = [x/y : 1 : 1/y]$ and using $\operatorname{ord}_O(x/y) = 1$, $\operatorname{ord}_O(1/y) = 3$ gives $\varphi(O) = [0 : 1 : 0]$. The Weierstrass polynomial is irreducible over $\bar{k}$: it is monic of degree two in y, so no nonconstant polynomial in x alone divides it, and a factorisation would be $(y - p(x))(y - r(x))$ with $p + r = -a_1x - a_3$ and $pr = -(x^3 + a_2x^2 + a_4x + a_6)$. Then $\deg p + \deg r = 3$ is odd, so $\deg p \neq \deg r$, and $\deg(p+r) = \max(\deg p, \deg r) \geq 2$, contradicting $\deg(p+r) \leq 1$. The image of φ is an irreducible closed subset of E (stated: images of projective varieties are closed) and not a point (as x is not constant), so it is all of E. By Proposition 8.22(ii), $[\bar{k}(C) : \bar{k}(x)] = \deg \operatorname{div}_\infty x = 2$ and $[\bar{k}(C) : \bar{k}(y)] = 3$; hence $[\bar{k}(C) : \bar{k}(x, y)]$ divides 2 and 3, so $\bar{k}(C) = \bar{k}(x, y) = \varphi^*\bar{k}(E)$ and φ is birational. If E were singular, it would be birational to $\mathbb{P}^1$: projecting from the singular point S, a line through S meets E in S with multiplicity at least two and in one further point (Theorem 8.12), which gives a birational map $E \dashrightarrow \mathbb{P}^1$, as for the node in Theorem 8.13. Then C would be birational to $\mathbb{P}^1$, hence isomorphic to it (Theorem 8.17), and of genus 0, a contradiction. So E is smooth, φ is a morphism of degree one between smooth projective curves, and it is an isomorphism by Theorem 8.17.

(iv) Genus one is Example 8.32(b); $[0 : 1 : 0]$ has coordinates in k. □

Proposition 8.34 (a genus-one curve is its own Pic^0)**.** *Let C have genus one and $O \in C(k)$. The map*

$$\kappa\colon C(\bar{k}) \to \mathrm{Pic}^0(C), \qquad P \mapsto \text{the class of } (P)-(O),$$

is a bijection, and $\kappa(\sigma P) = \sigma\kappa(P)$ for $\sigma \in G_k$. Hence $C(\bar{k})$ carries a unique group structure, with identity O, for which κ is an isomorphism, and G_k acts by group automorphisms.

Proof. Surjective: for $D \in \mathrm{Div}^0(C)$, $l(D+(O)) = 1$ by Corollary 8.30(e), so there is $f \neq 0$ with $\operatorname{div} f + D + (O) \geq 0$; this effective divisor has degree one, so it is (P) for a point P, and $D \sim (P)-(O)$. Injective: if $(P)-(O) \sim (Q)-(O)$ then $(P) \sim (Q)$, and $P \neq Q$ would force genus 0 (Corollary 8.30(d)). Equivariance: $\sigma((P)-(O)) = (\sigma P)-(O)$ because $\sigma O = O$, and σ preserves principal divisors (Proposition 8.22(iii)). □

Chapter 9 identifies this group law with the chord-tangent law of a Weierstrass cubic: if P, Q, R are the three intersections of a line $L = 0$ with E, then $(P)+(Q)+(R)-3(O) = \operatorname{div}(L/Z)$, so $\kappa(P)+\kappa(Q)+\kappa(R) = 0$. Associativity of the chord-tangent law, which is awkward to check directly, is then automatic.

In the paper 8.35. Appendix app:repro of the paper: every elliptic curve is given by a Weierstrass equation, as `ellinit([1,1,1,-30,-76])` for `121a1`; Theorem 8.33 is why this loses nothing. Proposition 8.34 says $E = \mathrm{Pic}^0(E) = J(E)$: an elliptic curve is its own Jacobian (Definition 8.65), which is what makes φ_E factor through $J_0(N)$ (Proposition 8.68(iv)) and lets the proof of Proposition prop:pullback speak of "the map $J_0(N) \to E$ induced by φ".

8.6 Morphisms and their degree; separability; the Frobenius morphism

The modular degree of the paper is the degree of the morphism $\varphi_E\colon X_0(N) \to E$. This section defines the degree of a nonconstant morphism of curves and proves that its descriptions agree: the degree of the extension of function fields, the number of preimages of a general point, the factor by which pullback multiplies degrees of divisors, and (over $\mathbb{C}$, in Sections 8.8 and 8.10) the topological degree on H^2. It also proves $\varphi_*\varphi^* = [\deg\varphi]$ on divisor classes, the identity behind the fact that $E \to J_0(N) \to E$ is multiplication by $\deg\varphi_E$ (Chapter 14), and introduces the Frobenius morphism used in Chapters 9 and 14.

Theorem 8.36 (nonconstant morphisms)**.** *A morphism $\varphi\colon C_1 \to C_2$ of curves is constant or surjective. If it is nonconstant, $\varphi^*\colon \bar{k}(C_2) \to \bar{k}(C_1)$, $f \mapsto f\circ\varphi$, is a well-defined injective homomorphism of fields fixing $\bar{k}$, and $\bar{k}(C_1)$ is a finite extension of $\varphi^*\bar{k}(C_2)$; if φ is defined over k, the same holds for $k(C_2) \to k(C_1)$.*

Proof. Surjectivity is [185, Chapter II, Theorem 2.3] (it uses that the image of a projective curve is closed); we do not prove it. Let φ be nonconstant, hence surjective. For $f \in \bar{k}(C_2)$, f is regular off a finite set S (Proposition 8.15(ii)), and $\varphi^{-1}(S)$ is a proper closed subset of C_1 (it is not all of C_1, as φ is surjective and $C_2 \neq S$), so $f\circ\varphi$ is a rational function on C_1. The map $f \mapsto f\circ\varphi$ respects sums and products, so it is a field homomorphism, injective as every field homomorphism is. Both fields are finitely generated of transcendence degree one over $\bar{k}$, and $\varphi^*\bar{k}(C_2)$ contains an element transcendental over $\bar{k}$ (the pullback of a nonconstant function); so $\bar{k}(C_1)$ is algebraic and finitely generated over $\varphi^*\bar{k}(C_2)$, hence finite. Over k the argument is the same. □

Definition 8.37 (degree, ramification index, pullback and pushforward)**.** Let $\varphi\colon C_1 \to C_2$ be a nonconstant morphism of smooth curves.

(i) $\deg\varphi = [\bar{k}(C_1) : \varphi^*\bar{k}(C_2)]$; $\deg_s\varphi$ and $\deg_i\varphi$ are the separable and inseparable degrees of this extension (Chapter 5), so $\deg\varphi = \deg_s\varphi \cdot \deg_i\varphi$; φ is *separable* (*purely inseparable*) if the extension is. A constant map has degree 0.

(ii) The *ramification index* of φ at P is $e_\varphi(P) = \operatorname{ord}_P(\varphi^* t_{\varphi(P)}) \geq 1$, for a uniformiser $t_{\varphi(P)}$ at $\varphi(P)$; it does not depend on the choice, since two uniformisers differ by a unit u and φ^*u is a unit at P.

(iii) $\varphi^*\colon \operatorname{Div}(C_2) \to \operatorname{Div}(C_1)$, $(Q) \mapsto \sum_{\varphi(P)=Q} e_\varphi(P)(P)$; $\varphi_*\colon \operatorname{Div}(C_1) \to \operatorname{Div}(C_2)$, $(P) \mapsto (\varphi(P))$; both extended linearly.

Theorem 8.38 (the degree formula)**.** *For a nonconstant morphism $\varphi\colon C_1 \to C_2$ of smooth projective curves and every $Q \in C_2(\bar{k})$,*

$$\sum_{P \in \varphi^{-1}(Q)} e_\varphi(P) = \deg\varphi.$$

Sketch of proof. Let $A = \bar{k}[C_2]_Q$, a discrete valuation ring with uniformiser $t = t_Q$, and B the integral closure of A in $\bar{k}(C_1)$ (identifying $\bar{k}(C_2)$ with its image under φ^*). Two facts are taken from the literature: B is a finitely generated A-module (finiteness of integral closure for finitely generated algebras over a field; [7, Chapter 5]), and the maximal ideals of B are the $\mathfrak{m}_P \cap B$ for the points $P \in \varphi^{-1}(Q)$, with $B_{\mathfrak{m}_P \cap B} = \bar{k}[C_1]_P$ (Theorem 8.13). Then B is a semilocal Dedekind domain, free over the principal ideal domain A (torsion-free and finitely generated, Chapter 3) of rank $n = \deg\varphi$, and $tB = \prod_P (\mathfrak{m}_P \cap B)^{e_\varphi(P)}$ by the definition of $e_\varphi(P)$. The argument of Chapter 6 for $\sum e_i f_i = n$ now applies: $\dim_{\bar{k}} B/tB = n$ by freeness, and by the Chinese remainder theorem $B/tB \simeq \prod_P B/(\mathfrak{m}_P \cap B)^{e_\varphi(P)}$, a product of spaces of dimensions $e_\varphi(P)$, because every residue field is $\bar{k}$ (all residue degrees are 1). See [185, Chapter II, Proposition 2.6] and [79, Chapter II, Proposition 6.9]. In the language of physics: the number of sheets of a branched cover, counted with multiplicity, does not jump. □

The simplest example shows every feature. Let $\varphi\colon \mathbb{P}^1 \to \mathbb{P}^1$, $z \mapsto z^n$, with $n \geq 1$. Then $\varphi^*\bar{k}(w) = \bar{k}(z^n)$, and z is a root of $T^n - z^n$, which is irreducible over $\bar{k}(z^n)$ (Eisenstein at the prime z^n of $\bar{k}[z^n]$), so $\deg\varphi = n$. Suppose $\operatorname{char} k \nmid n$. Over $a \neq 0, \infty$ the fibre is the n distinct roots of $z^n = a$, and at each of them $\varphi^*(w - a) = z^n - a$ has a simple zero: n points with $e = 1$. Over 0 the fibre is the single point 0, with $e_\varphi(0) = \operatorname{ord}_0(z^n) = n$; over ∞, with uniformiser $1/w$, $e_\varphi(\infty) = \operatorname{ord}_\infty(z^{-n}) = n$. In each case $\sum e_\varphi(P) = n$. If instead $n = p = \operatorname{char} k$, then $z^p - a = (z - a^{1/p})^p$, so every fibre is a single point with $e = p$: the map is a bijection on points, of degree p, and $\deg_s\varphi = 1$; this is the Frobenius morphism of Proposition 8.40.

Corollary 8.39 (the degree in three ways)**.** *Let $\varphi\colon C_1 \to C_2$ be a nonconstant morphism of smooth projective curves.*

(i) $\deg\varphi = [\bar{k}(C_1) : \varphi^*\bar{k}(C_2)]$ *(the definition).*

(ii) $\#\varphi^{-1}(Q) = \deg_s\varphi$ *for all but finitely many $Q \in C_2(\bar{k})$; if φ is separable (always in characteristic 0), $\#\varphi^{-1}(Q) = \deg\varphi$ for every Q outside the finite set of branch points (Definition 8.42).*

(iii) $\deg \varphi^* D = \deg\varphi \cdot \deg D$; $\varphi_*\varphi^* D = (\deg\varphi)D$; $\varphi^* \operatorname{div}(f) = \operatorname{div}(\varphi^* f)$; *and* $\varphi_* \operatorname{div}(h) = \operatorname{div}(\mathrm{N}\, h)$, *with* N *the norm from* $\bar{k}(C_1)$ *to* $\varphi^*\bar{k}(C_2)$ *(stated). Hence* φ^* *and* φ_* *induce homomorphisms* $\varphi^*\colon \operatorname{Pic}(C_2) \to \operatorname{Pic}(C_1)$ *and* $\varphi_*\colon \operatorname{Pic}(C_1) \to \operatorname{Pic}(C_2)$, *preserving* Pic^0, *and* $\varphi_*\varphi^* = [\deg\varphi]$ *on* $\operatorname{Pic}^0(C_2)$.

(iv) Over $\mathbb{C}$: $\deg\varphi$ *is the analytic degree of the holomorphic map* φ *(Theorem 8.48(c), Theorem 8.49), and* φ^* *on* $H^2(\cdot,\mathbb{Z}) = \mathbb{Z}$ *is multiplication by* $\deg\varphi$ *(Proposition 8.62(iv)).*

(v) $\deg(\psi\circ\varphi) = \deg\psi \cdot \deg\varphi$; *and* $\deg\varphi = 1$ *iff* φ *is an isomorphism.*

(vi) For nonconstant $f \in \bar{k}(C)$, *the morphism* $f\colon C \to \mathbb{P}^1$ *has degree* $[\bar{k}(C) : \bar{k}(f)] = \deg \operatorname{div}_0(f) = \deg \operatorname{div}_\infty(f)$. *Hence* $\deg \operatorname{div}(f) = 0$, *and a function without poles is constant.*

Proof. (iii) The first two identities follow from Theorem 8.38: $\deg \varphi^*(Q) = \sum_{P\mapsto Q} e_\varphi(P) = \deg\varphi$, and $\varphi_*\varphi^*(Q) = \sum_{P\mapsto Q} e_\varphi(P)(Q) = (\deg\varphi)(Q)$. For the third, let $Q = \varphi(P)$, $e = e_\varphi(P)$, $m = \operatorname{ord}_Q f$, and write $f = u t_Q^m$ with u a unit at Q. Then $\varphi^* f = (\varphi^* u)(\varphi^* t_Q)^m$, with $\varphi^* u$ a unit at P and $\operatorname{ord}_P \varphi^* t_Q = e$, so $\operatorname{ord}_P \varphi^* f = em$: the coefficient of P in $\varphi^* \operatorname{div}(f)$. The norm formula is [185, Chapter II, Section 3] (stated). So φ^* and φ_* map principal divisors to principal divisors and multiply, respectively preserve, degrees; they descend to Pic and Pic^0, and the divisor identity $\varphi_*\varphi^* = \deg\varphi$ descends.

(vi) For f nonconstant, $f^*\bar{k}(\mathbb{P}^1) = f^*\bar{k}(t) = \bar{k}(f)$, so the degree is $[\bar{k}(C) : \bar{k}(f)]$. The coordinate t is a uniformiser at $0 \in \mathbb{P}^1$, so $e_f(P) = \operatorname{ord}_P(f^* t) = \operatorname{ord}_P f$ at a zero P of f; and $1/t$ is a uniformiser at ∞, so $e_f(P) = -\operatorname{ord}_P f$ at a pole. Hence $f^*((0)) = \operatorname{div}_0(f)$ and $f^*((\infty)) = \operatorname{div}_\infty(f)$, both of degree $\deg f$ by Theorem 8.38. So $\deg \operatorname{div} f = 0$, and a nonconstant function has a pole divisor of degree $\deg f \geq 1$. This proves Proposition 8.15(iii) and Proposition 8.22(ii); neither was used in the proof of Theorem 8.38, which rests on the sketched facts named there.

(ii) For separable φ only finitely many points are ramified (Lemma 8.43), and over every other Q all $e_\varphi(P) = 1$, so $\#\varphi^{-1}(Q) = \deg\varphi$ by Theorem 8.38. In general φ factors as a purely inseparable morphism, which is bijective on points, followed by a separable one of degree $\deg_s\varphi$ (Proposition 8.40(b), stated).

(v) The first statement is the tower law for degrees of field extensions. If $\deg\varphi = 1$, φ^* is an isomorphism of function fields and φ is an isomorphism (Theorem 8.17); an isomorphism induces an isomorphism of function fields. (iv) is proved where cited. □

Table 8.1: The degree of a nonconstant morphism of smooth projective curves.

Proposition 8.40 (separability and the Frobenius morphism)**.**

(a) *In characteristic* 0 *every nonconstant morphism of curves is separable.*

(b) *In characteristic* p, φ *is separable iff* $\varphi^*\omega \neq 0$ *for one (equivalently every) nonzero differential* ω *on* C_2, *where* $\varphi^*(f\,dg) = (\varphi^* f)\,d(\varphi^* g)$. *For a power* r *of* p *and a curve* $C \subseteq \mathbb{P}^n$, *let* $C^{[r]}$ *(not to be confused with the twist notation* $E^{(q)}$ *of Appendix B) be the curve whose ideal is generated by the polynomials obtained from generators of* $I(C)$ *by raising their coefficients to the* r*-th power, and* $\pi_r\colon C \to C^{[r]}$, $[x_0 : \cdots : x_n] \mapsto [x_0^r : \cdots : x_n^r]$, *the* r-power Frobenius morphism *(it maps* C *into* $C^{[r]}$ *because* $F^{[r]}(x_0^r, \dots, x_n^r) = F(x_0, \dots, x_n)^r$, *where* $F^{[r]}$ *has the coefficients of* F *raised to the* r*-th power). Every nonconstant* φ *factors as* $C_1 \xrightarrow{\pi_r} C_1^{[r]} \xrightarrow{\lambda} C_2$ *with* $r = \deg_i \varphi$ *and* λ *separable (stated). For* C *defined over* $\mathbb{F}_q$, $C^{[q]} = C$ *and* π_q *is the morphism of the next item.*

(c) *Let* $k = \mathbb{F}_q$ *and* $C \subseteq \mathbb{P}^n$ *a curve defined over* $\mathbb{F}_q$. *The* q-power Frobenius morphism $\pi_q\colon [x_0 : \cdots : x_n] \mapsto [x_0^q : \cdots : x_n^q]$ *maps* C *to itself and is a bijection on* $C(\bar{\mathbb{F}}_q)$; $\pi_q^* \bar{\mathbb{F}}_q(C) = \bar{\mathbb{F}}_q(C)^q$; $d(\pi_q^* f) = 0$ *for every* f; π_q *is purely inseparable of degree* q *and* $e_{\pi_q}(P) = q$ *at every point; its fixed points are* $C(\mathbb{F}_q)$; *and on* $C(\bar{\mathbb{F}}_q)$ *it coincides with the action of the arithmetic Frobenius* $\mathrm{Frob}_q \in G_{\mathbb{F}_q}$.

Proof. (a) Fields of characteristic 0 are perfect, and every algebraic extension of a perfect field is separable (Chapter 5); here $\varphi^* \bar{k}(C_2)$ has characteristic 0. (b) is [185, Chapter II, Proposition 4.2(c) and Corollary 2.12]; we do not prove it.

(c) If F is a homogeneous polynomial with coefficients in $\mathbb{F}_q$, then $F(x_0^q, \dots, x_n^q)$ equals $F(x_0, \dots, x_n)^q$ (the freshman's dream, Chapter 2, and $a^q = a$ for $a \in \mathbb{F}_q$); so π_q maps C into C. On $\bar{\mathbb{F}}_q$ the map $a \mapsto a^q$ is a bijection, so π_q is a bijection of $\mathbb{P}^n(\bar{\mathbb{F}}_q)$ preserving $C(\bar{\mathbb{F}}_q)$; in particular it is nonconstant. For $f = F/G \in \bar{\mathbb{F}}_q(C)$ the pullback $\pi_q^* f = F(x^q)/G(x^q)$ equals $(F'/G')^q$, where the coefficients of F', G' are the q-th roots of those of F, G ($\bar{\mathbb{F}}_q$ is perfect); conversely every $(F'/G')^q$ is of this form. So $\pi_q^* \bar{\mathbb{F}}_q(C) = \bar{\mathbb{F}}_q(C)^q$, and $d(h^q) = q h^{q-1} dh = 0$. The degree $[\bar{\mathbb{F}}_q(C) : \bar{\mathbb{F}}_q(C)^q]$ is q: for a separating transcendental element t (one with $\bar{\mathbb{F}}_q(C)/\bar{\mathbb{F}}_q(t)$ separable, which exists, [185, Chapter II, Section 1]), $\bar{\mathbb{F}}_q(C) = \bar{\mathbb{F}}_q(C)^q(t)$ and t has minimal polynomial $X^q - t^q$ over $\bar{\mathbb{F}}_q(C)^q$ (sketched; [185, Chapter II, Proposition 2.11]). Every point has exactly one preimage, so $e_{\pi_q}(P) = q$ by Theorem 8.38. A point $[x_0 : \cdots : x_n]$, scaled so that some $x_i = 1$, is fixed iff $x_j^q = x_j$ for all j, that is, iff all $x_j \in \mathbb{F}_q$. Finally Frob_q acts on coordinates by $a \mapsto a^q$ (Convention 8.1(C7)). □

On $\mathbb{P}^1$ over $\mathbb{F}_q$ the sketched degree computation is immediate: $\pi_q^* \bar{\mathbb{F}}_q(t) = \bar{\mathbb{F}}_q(t^q)$, and t is a root of $X^q - t^q = (X - t)^q$, irreducible over $\bar{\mathbb{F}}_q(t^q)$ by Eisenstein, so $\deg \pi_q = q$, while $d(t^q) = 0$ shows that the extension is purely inseparable. Two features of (c) matter later. First, the morphism π_q and the Galois element Frob_q have the same effect on points but act differently on functions: $\pi_q^* f = f \circ \pi_q$ is $\bar{\mathbb{F}}_q$-linear in f, whereas Frob_q acts on $\bar{\mathbb{F}}_q(C)$ through the coefficients (Proposition 8.18(ii)), semilinearly. Second, because they agree on points, the arithmetic Frobenius is what π_q induces on torsion points and on $T_\ell J$, and its inverse, the geometric Frobenius, is what appears on H^1 (Theorem 8.74(d), Convention 8.63(e)). Since H^1 is the dual of $T_\ell J$, at a prime p of good reduction $\det(1 - \mathrm{Frob}_p^{-1} X \mid H^1) = \det(1 - \mathrm{Frob}_p X \mid T_\ell J)$; using Frob_p itself on H^1 would replace each eigenvalue α by α^{-1}. This is the convention behind the book's form $\det(1 - \mathrm{Frob}_p^{-1} p^{-s} \mid H^1)$ of the L-factors.

In the paper 8.41. Section 1 of the paper: "the $X_0(N)$-optimal curve, for which the modular parametrisation $\varphi_E\colon X_0(N) \to E$ has minimal degree" and "$\deg \varphi_E$ its *modular degree*". The

degree is that of Definition 8.37, and by Corollary 8.39 and Table 8.1 it is at once $[\mathbb{Q}(X_0(N)) : \varphi_E^*\mathbb{Q}(E)]$ (degrees of field extensions do not change under $\otimes_{\mathbb{Q}}\overline{\mathbb{Q}}$ for function fields of curves defined over $\mathbb{Q}$), the number of points of $X_0(N)(\mathbb{C})$ over a general point of $E(\mathbb{C})$, and the factor $\deg\varphi_E$ in $\varphi_{E*}\varphi_E^* = [\deg\varphi_E]$ on $E = \mathrm{Pic}^0(E)$. The proof of Proposition prop:pullback uses the cohomological form, "φ^* multiplies the fundamental class of H^2 by $\deg\varphi_E$", which is Proposition 8.62(iv). PARI's `ellmoddegree` computes this number (Chapter 22).

8.7 Ramification and the Riemann-Hurwitz formula

The Riemann-Hurwitz formula relates the genera of two curves joined by a morphism. In the book it gives the genus of $X_0(N)$ (Chapter 12), shows that isogenies are unramified (Chapter 9), and checks the modular degrees quoted in the paper against the genera of the modular curves (Corollary 8.45(e)).

Definition 8.42 (ramification)**.** Let $\varphi\colon C_1 \to C_2$ be nonconstant. φ is *unramified* at P if $e_\varphi(P) = 1$ and *ramified* otherwise, and $\varphi(P)$ is then a *branch point*. The ramification at P is *tame* if $\mathrm{char}\,k \nmid e_\varphi(P)$ and *wild* otherwise. φ is *unramified* if it is unramified at every point.

Lemma 8.43 (the local computation)**.** *Let $\varphi\colon C_1 \to C_2$ be nonconstant and separable, $\omega \neq 0$ a differential on C_2, $P \in C_1$, $Q = \varphi(P)$, $e = e_\varphi(P)$, and t_P, t_Q uniformisers. Then $\varphi^*\omega \neq 0$ and*

$$\mathrm{ord}_P(\varphi^*\omega) = e\,\mathrm{ord}_Q(\omega) + \mathrm{ord}_P\Big(\frac{d(\varphi^*t_Q)}{dt_P}\Big), \qquad \mathrm{ord}_P\Big(\frac{d(\varphi^*t_Q)}{dt_P}\Big) \geq e-1,$$

with equality iff $\mathrm{char}\,k \nmid e$. In particular only finitely many points of C_1 are ramified.

Proof. $\varphi^*\omega \neq 0$ by Proposition 8.40(b) (in characteristic 0 by Proposition 8.26(i): d of a separating element is nonzero). Write $\omega = g\,dt_Q$ and $\varphi^*t_Q = ut_P^e$ with u a unit at P. Then $\varphi^*\omega = (\varphi^*g)\,d(ut_P^e)$ and

$$\frac{d(ut_P^e)}{dt_P} = eut_P^{e-1} + t_P^e\frac{du}{dt_P},$$

where du/dt_P is regular at P (Proposition 8.26(ii)). If $\mathrm{char}\,k \nmid e$, the first term has order exactly $e-1$ and the second order at least e, so the sum has order $e-1$. If $\mathrm{char}\,k \mid e$, the first term vanishes and the order is at least e. Since $\mathrm{ord}_P\,\varphi^*g = e\,\mathrm{ord}_Q\,g$ (Corollary 8.39(iii)), the formula follows. At a ramified P the second term is $\geq e-1 \geq 1$; but it equals $\mathrm{ord}_P\,\varphi^*\omega - e\,\mathrm{ord}_Q\,\omega$, which is nonzero only at the finitely many zeros and poles of $\varphi^*\omega$ and points over zeros and poles of ω (Proposition 8.26(ii), Theorem 8.36: fibres are finite by Theorem 8.38). □

Theorem 8.44 (Riemann-Hurwitz)**.** *Let $\varphi\colon C_1 \to C_2$ be a nonconstant separable morphism of smooth projective curves of genera g_1, g_2. Then*

$$2g_1 - 2 \;\geq\; \deg\varphi\,(2g_2-2) + \sum_{P\in C_1}(e_\varphi(P)-1),$$

with equality iff every ramification is tame; in particular with equality in characteristic 0.

Proof. Take $\omega \neq 0$ on C_2 and sum the formula of Lemma 8.43 over $P \in C_1$. The first terms give $\sum_Q \mathrm{ord}_Q(\omega)\sum_{P\mapsto Q} e_\varphi(P) = \deg\varphi\cdot\deg\mathrm{div}(\omega)$ by Theorem 8.38, that is $\deg\varphi\,(2g_2-2)$ by Corollary 8.30(b); the left side is $\deg\mathrm{div}(\varphi^*\omega) = 2g_1-2$. The second terms are $\geq\sum(e_\varphi(P)-1)$, with equality iff equality holds at every P, that is, iff all ramification is tame. □

A topological proof over $\mathbb{C}$ is sketched in Theorem 8.50(c): triangulate C_2 with the branch points among the vertices, lift the triangulation and count $V - E + F$.

For $z \mapsto z^n$ on $\mathbb{P}^1$ with $\operatorname{char} k \nmid n$ (the example after Theorem 8.38) the formula reads $-2 = n(-2) + (n-1) + (n-1)$, with the two ramification points 0 and ∞. Wild ramification is genuinely different. In characteristic p let $\varphi\colon \mathbb{P}^1 \to \mathbb{P}^1$ be $y \mapsto x = y^p - y$ (the Artin-Schreier map). It has degree p (y is a root of $T^p - T - x$, irreducible over $\bar{k}(x)$ because the map is totally ramified at ∞, as we now see) and is separable, because $d(y^p - y) = -dy \neq 0$ (Proposition 8.40(b)). At finite points $dx/dy = -1$ is a unit, so φ is unramified there. At ∞, with uniformisers $t_P = 1/y$ and $t_Q = 1/x$,

$$\varphi^* t_Q = \frac{1}{y^p - y} = \frac{t_P^p}{1 - t_P^{p-1}}, \qquad \frac{d(\varphi^* t_Q)}{dt_P} = \frac{p t_P^{p-1}}{1 - t_P^{p-1}} + \frac{(p-1)t_P^{2p-2}}{(1 - t_P^{p-1})^2} = \frac{-t_P^{2p-2}}{(1 - t_P^{p-1})^2},$$

so $e_\varphi(\infty) = p$, wild, and the order in Lemma 8.43 is $2p-2$, strictly larger than $e - 1 = p - 1$. With $2p-2$ the exact formula of the proof gives $-2 = p(-2) + (2p-2)$, which is correct, while the tame count $\sum(e_\varphi(P) - 1) = p - 1$ gives the strict inequality $-2 > -2p + (p-1)$ of the theorem. (The degree claim: the fibre over ∞ is one point with $e = p$, so $\deg \varphi = p$ by Theorem 8.38, and $T^p - T - x$, having y as a root and degree p, is the minimal polynomial.)

Corollary 8.45 (consequences and examples)**.** *Let $\varphi\colon C_1 \to C_2$ be nonconstant and separable.*

(a) If $g_2 \geq 1$ then $g_1 \geq g_2$. If $g_1 = 0$ then $g_2 = 0$ (Lueroth's theorem, for separable maps).

(b) If $g_1 = g_2 = 1$ then φ is unramified, and $\#\varphi^{-1}(Q) = \deg \varphi$ for every Q. In characteristic 0 this applies to every nonconstant morphism between genus-one curves, in particular to every isogeny (Chapter 9).

(c) The double cover $x\colon C \to \mathbb{P}^1$ of the hyperelliptic curve C given by $y^2 = h(x)$, h squarefree of degree $2g+1$ or $2g+2$, $\operatorname{char} k \neq 2$, is branched exactly at the $2g+2$ points consisting of the roots of h and, if $\deg h$ is odd, ∞; so $g(C) = g$.

(d) The projection $[X : Y : Z] \mapsto [X : Y]$ of the Fermat curve $X^d + Y^d + Z^d = 0$, $\operatorname{char} k \nmid d$, has degree d and is totally ramified ($e = d$) over the d roots of $X^d + Y^d = 0$ and unramified elsewhere; so $2g - 2 = -2d + d(d-1)$ and $g = \frac{(d-1)(d-2)}{2}$, as in Theorem 8.31.

(e) Over $\mathbb{C}$, for a nonconstant $\varphi\colon X \to E$ with $g(E) = 1$: $\sum_P (e_\varphi(P) - 1) = 2g(X) - 2$, whatever $\deg \varphi$. For the paper's curves (genera from Example 8.32(f), degrees from Cremona's tables, checked with PARI's `ellmoddegree`):

φ_E	$g(X_0(N))$	$\deg \varphi_E$	$\sum_P (e_\varphi(P) - 1)$
$X_0(11) \to$ `11a1`	1	1	0
$X_0(20) \to$ `20a1`	1	1	0
$X_0(121) \to$ `121a1`	6	6	10
$X_0(539) \to$ `539c1`	49	$288 = 2^5 \cdot 3^2$	96

A morphism of degree one is an isomorphism, so $X_0(11) \simeq$ `11a1` and $X_0(20) \simeq$ `20a1` over $\mathbb{Q}$: these modular curves are elliptic curves.

(f) (Forward pointer.) The genus formula for $X_0(N)$ in Chapter 12 is Theorem 8.44 for the morphism $X_0(N) \to X_0(1) \simeq \mathbb{P}^1$, of degree $[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)]$, ramified only over $j = 0$, 1728, ∞.

Proof. (a) If $g_2 \geq 1$ the theorem gives $2g_1 - 2 \geq \deg\varphi(2g_2-2) \geq 2g_2 - 2$. If $g_1 = 0$ and $g_2 \geq 1$, the right side is $\geq 0 > -2$, a contradiction. (b) $0 \geq 0 + \sum(e_\varphi(P) - 1)$, so every $e_\varphi(P) = 1$, and Theorem 8.38 gives $\#\varphi^{-1}(Q) = \deg\varphi$ for every Q.

(c) $y \notin \bar{k}(x)$ because h is not a square, so $[\bar{k}(C) : \bar{k}(x)] = 2$, and the map is separable as $\operatorname{char} k \neq 2$. Over $a \in \bar{k}$ the points of C are $(a, \pm\sqrt{h(a)})$: two points, hence $e = 1$ at both, if $h(a) \neq 0$, and one point, hence $e = 2$, if $h(a) = 0$. Over ∞: the smooth projective model is covered by the affine curve $y^2 = h(x)$ and the affine curve $w^2 = H(s)$, $H(s) = s^{2g+2}h(1/s)$, glued by $s = 1/x$, $w = ys^{g+1}$ ([185, Chapter II, Exercise 2.14], exercise number not verified); H is squarefree, $H(0)$ is the leading coefficient of h if $\deg h = 2g+2$, and H has a simple zero at 0 if $\deg h = 2g+1$. So ∞ is a branch point iff $\deg h$ is odd. All ramification is tame, and the theorem gives $2g(C) - 2 = 2(-2) + (2g+2)$.

(d) The map is defined everywhere ($X = Y = 0$ forces $Z = 0$). The fibre over $[a : b]$ is $\{[a : b : z] : z^d = -(a^d + b^d)\}$: d distinct points if $a^d + b^d \neq 0$, and the single point $[a : b : 0]$ otherwise. The extension $\bar{k}(C)/\bar{k}(X/Y)$ is generated by Z/Y, a root of $T^d + (X/Y)^d + 1$, which is irreducible (Eisenstein at a simple root of $s^d + 1$) and separable ($\operatorname{char} k \nmid d$); so the degree is d, and by Theorem 8.38 the single point over a root of $X^d + Y^d$ has $e = d$. All ramification is tame. (e) is the theorem with $g_2 = 1$; the table uses $2g - 2 = 0, 0, 10, 96$. □

8.8 Compact Riemann surfaces and smooth projective complex curves

$X_0(N)$ is built analytically in Chapter 12, as a compact Riemann surface, and used algebraically in Chapter 14 and in the paper, as a curve over $\mathbb{Q}$; the modular parametrisation φ_E is at once a holomorphic map and a morphism. This section introduces compact Riemann surfaces, proves the local normal form of holomorphic maps (which gives the analytic degree), and states the dictionary between the two languages (Theorem 8.49), summarised in Table 8.2. The prerequisites are those of Appendix A: holomorphic functions, zeros of finite order, the inverse function theorem, compactness and connectedness.

Definition 8.46 (Riemann surfaces)**.** A *Riemann surface* is a connected Hausdorff topological space X with a countable basis, together with a maximal atlas of *charts* $z\colon U \to z(U) \subseteq \mathbb{C}$ (homeomorphisms from open sets of X onto open subsets of $\mathbb{C}$, the U covering X) whose transition maps $z_2 \circ z_1^{-1}$ are holomorphic where defined. A function $f\colon U \to \mathbb{C}$ on an open subset is *holomorphic* (*meromorphic*) if $f \circ z^{-1}$ is, for every chart z; $\mathcal{M}(X)$ is the field of meromorphic functions on X (for X connected, Appendix A). A continuous map $F\colon X \to Y$ of Riemann surfaces is *holomorphic* if $w \circ F \circ z^{-1}$ is holomorphic for all charts z of X and w of Y.

Example 8.47 (Riemann surfaces)**.**

(a) $\mathbb{C}$, and every connected open subset of $\mathbb{C}$, with the identity chart.

(b) The Riemann sphere $\mathbb{P}^1(\mathbb{C}) = \mathbb{C} \cup \{\infty\}$, with the charts z on $\mathbb{C}$ and $w = 1/z$ on $\mathbb{P}^1 \setminus \{0\}$; the transition map $w = 1/z$ is holomorphic on $\mathbb{C}^\times$. It is compact.

(c) $\mathbb{C}/\Lambda$ for a lattice $\Lambda = \mathbb{Z}\omega_1 + \mathbb{Z}\omega_2$ (ω_1, ω_2 linearly independent over $\mathbb{R}$): the charts are local inverses of the projection $\mathbb{C} \to \mathbb{C}/\Lambda$ on discs of radius less than half the shortest nonzero vector of Λ; the transition maps are translations $z \mapsto z + \lambda$. It is compact (the image of a closed parallelogram) and, topologically, a torus. Chapter 9 proves that every elliptic curve over $\mathbb{C}$ is of this form.

(d) The smooth points of an affine plane curve $f(x,y)=0$ over $\mathbb{C}$: near a point with $f_y \neq 0$, the holomorphic implicit function theorem writes the curve as a graph $y=y(x)$, and x is a chart; near a point with $f_x \neq 0$, y is a chart; the transition maps are holomorphic.

(e) Hence $C(\mathbb{C})$ is a compact Riemann surface for every smooth projective curve C over $\mathbb{C}$: it is covered by the affine charts, it is closed in the compact space $\mathbb{P}^n(\mathbb{C})$, and it is connected because C is irreducible (stated; [79, Appendix B], [136, Chapter VII], chapter number not verified).

(f) (Forward pointer, Chapter 12.) $\Gamma_0(N)\backslash\mathcal{H}$, compactified by adding the finitely many cusps, with special charts at the cusps and at the elliptic points, is the compact Riemann surface $X_0(N)(\mathbb{C})$.

Theorem 8.48 (holomorphic maps of compact Riemann surfaces)**.** *Let $F\colon X \to Y$ be a nonconstant holomorphic map of compact Riemann surfaces.*

(a) (Local normal form.) For each $P \in X$ there are charts z at P and w at $F(P)$, centred at 0, in which F is $w=z^e$. The integer $e=\operatorname{mult}_P(F)\geq 1$ does not depend on the charts.

(b) F is open and surjective, and its fibres are finite.

(c) The number $d=\sum_{P\in F^{-1}(Q)}\operatorname{mult}_P(F)$ does not depend on $Q\in Y$; it is the degree *of F.*

(d) $\operatorname{mult}_P(F)=1$ except at finitely many points of X; so $\#F^{-1}(Q)=d$ except for finitely many Q.

(e) F preserves orientation: in local coordinates its real Jacobian determinant is $|h'(z)|^2\geq 0$.

Proof. (a) Take any charts z at P and w at $F(P)$, centred at 0, and put $h=w\circ F\circ z^{-1}$, holomorphic near 0 with $h(0)=0$. h is not identically zero near 0: otherwise, by the identity theorem and connectedness of X, F would be constant. So $h(z)=z^e g(z)$ with $e\geq 1$ and $g(0)\neq 0$. On a small disc g has a holomorphic e-th root g_1 (Appendix A: a nonvanishing function on a disc has a holomorphic logarithm), and $\zeta=zg_1(z)$ has $\zeta'(0)=g_1(0)\neq 0$, so it is a chart near P by the inverse function theorem. In the charts ζ, w the map is $w=\zeta^e$. The exponent e is the order of vanishing at 0 of $w\circ F$ in any chart at P; changing the chart at P or at $F(P)$ composes with a biholomorphism fixing 0, whose derivative at 0 is nonzero, and this does not change the order of a zero.

(b) The map $\zeta\mapsto\zeta^e$ is open, so by (a) F is open. Then $F(X)$ is open, and compact, hence closed; Y is connected, so $F(X)=Y$. By (a), P is the only preimage of $F(P)$ near P; so fibres are discrete, and they are closed in the compact X, hence finite.

(c) Let $F^{-1}(Q)=\{P_1,\dots,P_r\}$, with multiplicities e_i and normal-form charts on pairwise disjoint neighbourhoods U_i of P_i. There is a neighbourhood V of Q with $F^{-1}(V)\subseteq\bigcup U_i$: otherwise there are $x_n\notin\bigcup U_i$ with $F(x_n)\to Q$; a subsequence converges (compactness) to some $x\notin\bigcup U_i$ (the complement is closed) with $F(x)=Q$, which is absurd. Shrinking V, every $Q'\in V\setminus\{Q\}$ has exactly e_i preimages in U_i (the e_i-th roots of $w(Q')\neq 0$), each of multiplicity one since $\frac{d}{d\zeta}\zeta^{e_i}\neq 0$ for $\zeta\neq 0$. So $Q'\mapsto\sum_{F(P)=Q'}\operatorname{mult}_P(F)$ is constant on V; it is locally constant, hence constant on the connected Y.

(d) In the normal form at P, every point near P other than P has multiplicity one. So the set of points of multiplicity ≥ 2 is discrete; it is also closed (its complement is open by the same remark), hence finite since X is compact. Over Q outside its finite image, $\#F^{-1}(Q)=d$ by (c).

(e) For $h = u + iv$ holomorphic, $\det\left(\begin{smallmatrix} u_x & u_y \\ v_x & v_y \end{smallmatrix}\right) = u_x^2 + v_x^2 = |h'|^2$ by the Cauchy-Riemann equations. □

The proofs of (a) and the openness in (b) use only that the target is a Riemann surface, not that it is compact. Hence *a holomorphic function $f\colon X \to \mathbb{C}$ on a compact Riemann surface is constant*: otherwise $f(X)$ would be open in $\mathbb{C}$, and also compact, hence closed and bounded, which is impossible for a nonempty open subset of $\mathbb{C}$. (The same follows from the maximum modulus principle, Appendix A.)

Theorem 8.49 (Riemann existence and GAGA for curves; stated)**.**

(a) (Riemann.) On a compact Riemann surface X the meromorphic functions separate points and give local coordinates at every point, and $\mathcal{M}(X)$ is a function field of one variable over $\mathbb{C}$.

(b) (Equivalence.) $X \mapsto$ the smooth projective curve with function field $\mathcal{M}(X)$, and $C \mapsto C(\mathbb{C})$, are inverse equivalences between compact Riemann surfaces with nonconstant holomorphic maps and smooth projective curves over $\mathbb{C}$ with nonconstant morphisms. Under them: meromorphic functions are rational functions; the order of a zero or pole is ord_P*; $\operatorname{mult}_P(F) = e_F(P)$; the analytic degree of Theorem 8.48(c) is* $\deg F$ *of Definition 8.37; meromorphic and holomorphic* 1*-forms (Definition 8.51) are the differentials and the regular differentials of Definition 8.25; divisors, linear equivalence and* Pic *agree.*

(c) The algebraic genus $g = l(K_C)$ equals the topological genus of Theorem 8.50.

We do not prove this; see [136, Chapters VI and VII] (Riemann existence and the algebraic curve of a Riemann surface), [79, Appendix B] (GAGA), and [70, Sections 14 and 16] (all section and chapter numbers not verified). Once (b) is granted, $\operatorname{mult}_P(F) = e_F(P)$ is a tautology: the multiplicity is the order of vanishing of $w \circ F$ at P for a local coordinate w at $F(P)$, which is $\operatorname{ord}_P(F^* t_{F(P)})$. In particular $\deg \varphi_E$ means the same in the analytic and the algebraic sense.

smooth projective curve C over $\mathbb{C}$	compact Riemann surface $X = C(\mathbb{C})$
function field $\mathbb{C}(C)$	meromorphic functions $\mathcal{M}(X)$
$\operatorname{ord}_P f$ (valuation of $\bar{k}[C]_P$)	order of zero or pole in a chart
ramification index $e_\varphi(P)$	multiplicity $\operatorname{mult}_P(\varphi)$, normal form $w = z^e$
$\deg \varphi = [\mathbb{C}(C_1) : \varphi^* \mathbb{C}(C_2)]$	number of sheets; degree on H^2

genus $g = l(K_C)$	$\dim H^0(X, \Omega^1)$; number of handles; $\frac{1}{2}\operatorname{rank} H_1(X, \mathbb{Z})$
$\operatorname{Pic}^0(C)$	$H^0(X, \Omega^1)^\vee / H_1(X, \mathbb{Z})$ (Abel-Jacobi)

Table 8.2: The dictionary of Theorems 8.49, 8.50, 8.54 and 8.66.

Theorem 8.50 (topology of compact Riemann surfaces)**.**

(a) A compact Riemann surface is an orientable compact surface, homeomorphic to a sphere with g handles for a unique $g \geq 0$, its topological genus*; its Euler characteristic is $\chi(X) = 2 - 2g$ (stated).*

(b) This g is the genus of Theorem 8.29 (stated; Theorem 8.49(c)).

(c) *(Topological Riemann-Hurwitz.) For* $F\colon X \to Y$ *holomorphic of degree* d, $\chi(X) = d\,\chi(Y) - \sum_P (\mathrm{mult}_P(F) - 1)$.

Sketch of proof of (c). Triangulate Y so that the finitely many branch points are vertices. Away from the branch points F is a d-sheeted covering (Theorem 8.48(c), (d)), so each open face and each open edge has exactly d lifts, and these lifts triangulate X. A vertex Q has $\#F^{-1}(Q) = d - \sum_{F(P)=Q}(\mathrm{mult}_P(F)-1)$ lifts. Counting, $V_X - E_X + F_X = d(V_Y - E_Y + F_Y) - \sum_P(\mathrm{mult}_P(F)-1)$. For (a) and (b) see [136, Chapters I and II] and [70, Section 17] (not verified). This is Euler's $V - E + F$ for a branched cover; with $\chi = 2 - 2g$ it is Theorem 8.44 over $\mathbb{C}$. □

For example, triangulate the sphere $Y = \mathbb{P}^1(\mathbb{C})$ as a double pyramid over a triangle, with apexes 0 and ∞ and the equator $|w| = 1$ divided into three edges: $V = 5$, $E = 9$, $F = 6$, $\chi = 2$. The map $z \mapsto z^2$ is branched only over 0 and ∞, each with one preimage of multiplicity 2. The three equatorial vertices have two lifts each, every edge and face has two lifts, and the apexes have one lift each: $V = 8$, $E = 18$, $F = 12$, so $\chi(X) = 2 = 2 \cdot 2 - (1 + 1)$, in agreement with (c) and with $X \simeq \mathbb{P}^1$.

8.9 Holomorphic differentials, residues, periods

Holomorphic 1-forms are the analytic face of regular differentials. In the book they are the weight-two cusp forms ($f \mapsto f(z)\,dz$ identifies $S_2(\Gamma_0(N))$ with $H^0(X_0(N), \Omega^1)$, Chapter 12), and their periods give the period lattice Λ_E and the Jacobian. In the paper, positivity (Theorem 8.55(b)) is the positivity of the Petersson norm $\langle f, f\rangle$ and of the area $\mathrm{vol}(\Lambda_E)$ in the formula of Zagier and Watkins (Remark rem:degree; Chapter 14), and $\varphi^* H^1(E, \mathbb{C})$ in the proof of Proposition prop:pullback is spanned by $\varphi^*\omega_E$ and its conjugate (Proposition 8.59(iii)).

Definition 8.51 (1-forms on a Riemann surface)**.** A *meromorphic* (*holomorphic*) 1-form ω on X is given in each chart z by $f(z)\,dz$ with f meromorphic (holomorphic), the expressions in two charts being related by $f(z)\,dz = f(z(w))z'(w)\,dw$. $\mathrm{ord}_P\,\omega = \mathrm{ord}_P\,f$ in a chart at P; $\mathrm{div}\,\omega = \sum \mathrm{ord}_P(\omega)(P)$; the *residue* $\mathrm{res}_P\,\omega$ is the coefficient of z^{-1} in the Laurent expansion of f in a chart centred at P. $H^0(X, \Omega^1)$ is the complex vector space of holomorphic 1-forms. Smooth real or complex 1-forms $p\,dx + q\,dy$ and 2-forms $r\,dx \wedge dy$, the exterior derivative d, the wedge product and $\int_X$ of 2-forms (with the orientation of Convention 8.1(C6)) are defined chartwise as on open subsets of $\mathbb{R}^2$, using a partition of unity for $\int_X$; Stokes' theorem $\int_M d\theta = \int_{\partial M}\theta$ holds for a compact surface M with smooth boundary (Appendix A; [136, Chapter IV]). A 1-form θ is *closed* if $d\theta = 0$, *exact* if $\theta = dg$ for a smooth function g; line integrals $\int_\gamma \theta$ along piecewise smooth paths are defined chartwise.

The residue does not depend on the chart: $\mathrm{res}_P\,\omega = \frac{1}{2\pi i}\oint_\gamma \omega$ for a small positively oriented loop γ around P in a chart, by the residue theorem of complex analysis, and the line integral is chart-independent. A holomorphic 1-form is closed: $d(f\,dz) = \frac{\partial f}{\partial \bar z}\,d\bar z \wedge dz = 0$. Examples: dz on $\mathbb{C}/\Lambda$ is a holomorphic 1-form without zeros (the transition maps are translations, with derivative 1); on $\mathbb{P}^1$, $dz = -w^{-2}dw$ has a double pole at ∞, and there is no nonzero holomorphic 1-form, as in Proposition 8.26(iv).

Theorem 8.52 (the residue theorem on a compact Riemann surface)**.** *For a meromorphic* 1*-form* ω *on a compact Riemann surface* X, $\sum_{P \in X} \mathrm{res}_P\,\omega = 0$.

Proof. ω has finitely many poles $P_1,\dots,P_r$ (they are isolated in the compact X). Choose pairwise disjoint closed coordinate discs Δ_j around P_j and put $M = X \setminus \bigcup_j \operatorname{int}\Delta_j$, a compact surface with boundary $\partial M = \bigcup \partial\Delta_j$, each circle oriented clockwise as seen from its disc (the boundary orientation of M). On M, ω is holomorphic, hence closed, so Stokes gives $0 = \int_M d\omega = \int_{\partial M}\omega = -\sum_j \oint_{\partial\Delta_j}\omega = -2\pi i\sum_j \operatorname{res}_{P_j}\omega$, the circles $\partial\Delta_j$ now oriented counterclockwise. □

On $\mathbb{P}^1$ the form dz/z has residue 1 at 0, and in the chart $w = 1/z$ at ∞ it is $-w^{-2}dw/w^{-1} = -dw/w$, with residue -1: the sum is 0. Compactness is what makes the theorem work: on $\mathbb{C}$ alone, dz/z has the single residue 1. The point at infinity carries the missing residue, just as a closed surface admits no net flux out of it.

Corollary 8.53 (the argument principle)**.** *For $f \in \mathcal{M}(X)^\times$, $\deg\operatorname{div}(f) = \sum_P \operatorname{res}_P(df/f) = 0$.*

Proof. In a chart at P write $f = z^m u$ with $m = \operatorname{ord}_P f$ and u holomorphic and nonzero near 0; then $df/f = m\,dz/z + du/u$, and du/u is holomorphic, so $\operatorname{res}_P(df/f) = m$. Apply Theorem 8.52. □

This is a second proof of Proposition 8.22(ii) over $\mathbb{C}$, independent of Theorem 8.38. In the language of physics: the total charge on a closed surface is zero.

Theorem 8.54 (the genus counts holomorphic forms)**.** *For a compact Riemann surface X of genus g, $\dim_{\mathbb{C}} H^0(X,\Omega^1) = g$, and $\deg\operatorname{div}\omega = 2g-2$ for every meromorphic 1-form $\omega \neq 0$.*

Proof. By Theorem 8.49(b), holomorphic 1-forms are regular differentials and meromorphic ones are differentials, so this is Corollary 8.30(a), (b) (proved there from the stated Riemann-Roch theorem). □

Examples: $H^0(\mathbb{C}/\Lambda,\Omega^1) = \mathbb{C}\,dz$ (a holomorphic form is $f\,dz$ with f holomorphic on the compact $\mathbb{C}/\Lambda$, hence constant); $H^0(\mathbb{P}^1,\Omega^1) = 0$. Forward pointer: $\dim S_2(\Gamma_0(N)) = g(X_0(N))$ (Chapter 12), for instance $\dim S_2(\Gamma_0(121)) = 6$.

Theorem 8.55 (Riemann's bilinear relations)**.** *Let X be a compact Riemann surface of genus $g \geq 1$ and $a_1,\dots,a_g,b_1,\dots,b_g$ a symplectic basis of $H_1(X,\mathbb{Z})$ (Theorem 8.57). For a closed 1-form θ put $A_j(\theta) = \int_{a_j}\theta$ and $B_j(\theta) = \int_{b_j}\theta$.*

(a) For $\omega,\eta \in H^0(X,\Omega^1)$, $\int_X \omega\wedge\eta = 0$.

(b) For $\omega \in H^0(X,\Omega^1)$, $\omega \neq 0$: $\frac{i}{2}\int_X \omega\wedge\bar\omega > 0$.

(c) For closed 1-forms θ, η: $$\int_X \theta\wedge\eta = \sum_{j=1}^{g}\bigl(A_j(\theta)B_j(\eta) - B_j(\theta)A_j(\eta)\bigr).$$

(d) For $\omega,\eta \in H^0(X,\Omega^1)$, and for $\omega \neq 0$ respectively,

$$\sum_j \bigl(A_j(\omega)B_j(\eta) - B_j(\omega)A_j(\eta)\bigr) = 0, \qquad \sum_j \operatorname{Im}\bigl(\overline{A_j(\omega)}B_j(\omega)\bigr) > 0.$$

(e) A holomorphic 1-form with all A-periods zero is zero. The period map $H_1(X,\mathbb{Z}) \to H^0(X,\Omega^1)^\vee$, $\gamma \mapsto (\omega \mapsto \int_\gamma\omega)$, is injective, and its image Λ_X is a lattice in the g-dimensional complex vector space $H^0(X,\Omega^1)^\vee$.

Proof. (a) Locally $\omega \wedge \eta = fg\, dz \wedge dz = 0$. (b) Locally $\omega = f\, dz$ and $\frac{i}{2}\omega \wedge \bar{\omega} = \frac{i}{2}|f|^2 dz \wedge d\bar{z} = |f|^2 dx \wedge dy$, since $dz \wedge d\bar{z} = -2i\, dx \wedge dy$; the integral of this nonnegative density is positive unless $f \equiv 0$. (In physical terms $\frac{i}{2}\int \omega \wedge \bar{\omega} = \int |f|^2\, dx\, dy$ is a squared norm; the Petersson product of Chapter 12 is $\langle f, g\rangle = \frac{i}{2}\int_{X_0(N)} f\, dz \wedge \overline{g\, dz}$, Appendix B, B-C8.) (d) The first identity is (c) with (a). For the second apply (c) to $\theta = \omega$, $\eta = \bar{\omega}$, using $A_j(\bar{\omega}) = \overline{A_j(\omega)}$: $\frac{i}{2}\int \omega \wedge \bar{\omega} = \frac{i}{2}\sum_j (A_j \bar{B}_j - \overline{A_j \bar{B}_j}) = \frac{i}{2} \cdot 2i \operatorname{Im} \sum_j A_j \bar{B}_j = \sum_j \operatorname{Im}(\bar{A}_j B_j)$, positive by (b). (e) If all $A_j(\omega) = 0$, the sum in (d) is zero, so $\omega = 0$. If $\int_\gamma \omega = 0$ for all ω, then also $\int_\gamma \bar{\omega} = 0$, so γ pairs to zero with $H^0(X, \Omega^1) \oplus \overline{H^0(X, \Omega^1)}$, which is all of $H^1(X, \mathbb{C})$ (Proposition 8.59(iii)); as $H_1(X, \mathbb{Z})$ is free and $H^1(X, \mathbb{C}) = \operatorname{Hom}(H_1(X, \mathbb{Z}), \mathbb{C})$, $\gamma = 0$. The same argument with real coefficients shows that the $\mathbb{R}$-linear extension $H_1(X, \mathbb{Z}) \otimes \mathbb{R} \to H^0(X, \Omega^1)^\vee$ is injective; both sides have real dimension $2g$ (Theorem 8.57, Theorem 8.54), so it is an isomorphism, and the image of $H_1(X, \mathbb{Z})$ is a lattice. □

Sketch of proof of (c). Cut X along loops representing the symplectic basis, all through one point; the result is a $4g$-gon Π whose sides are identified in the pattern $a_1 b_1 a_1^{-1} b_1^{-1} \cdots a_g b_g a_g^{-1} b_g^{-1}$. On the simply connected Π, $\theta = dF$ for a smooth function F, and Stokes gives $\int_X \theta \wedge \eta = \int_\Pi d(F\eta) = \int_{\partial\Pi} F\eta$, because $d(F\eta) = dF \wedge \eta + F\, d\eta = \theta \wedge \eta$ (η is closed); here $\partial\Pi$ is traversed counterclockwise, which for the torus of Example 8.61 is the word $aba^{-1}b^{-1}$ with $a \cdot b = +1$. Fix j and label the vertices of the block $a_j b_j a_j^{-1} b_j^{-1}$ as $v_0 \xrightarrow{a_j} v_1 \xrightarrow{b_j} v_2 \xrightarrow{a_j^{-1}} v_3 \xrightarrow{b_j^{-1}} v_4$. A point $p(s)$ on the first side and the point $p'(s)$ on the third side that is glued to it lie over the same point of a_j, the third side running from v_3 ($s = 0$) to v_2 ($s = 1$). The difference $F(p'(s)) - F(p(s))$ is constant in s: its derivative is θ evaluated on the same tangent vector of a_j, minus itself. At $s = 1$ it is $F(v_2) - F(v_1) = \int_{v_1}^{v_2} dF = B_j(\theta)$. As the third side is traversed against a_j, the two sides contribute

$$\int_{a_j} (F(p) - F(p'))\eta = -B_j(\theta) A_j(\eta).$$

In the same way a point $q(s)$ of the second side and the glued point $q'(s)$ of the fourth (running from v_4 at $s = 0$ to v_3 at $s = 1$) have $F(q') - F(q)$ constant, equal at $s = 1$ to $F(v_3) - F(v_2) = -A_j(\theta)$, and the two sides contribute $\int_{b_j} (F(q) - F(q'))\eta = A_j(\theta) B_j(\eta)$. Summing over j gives (c). On the torus, with $\theta = ds$, $\eta = dt$ and $F = s$, the two contributions are 0 and 1. What is not proved here is that cutting along the loops of a symplectic basis gives such a polygon. See [136, Chapter VIII] and [75, Chapter 2, Section 2] (sections not verified). On the torus (Example 8.61) the formula is checked directly. □

In the language of physics: for $X = \mathbb{C}/\Lambda$ and $\omega = dz$, (b) is the area of a period parallelogram, $\frac{i}{2}\int dz \wedge d\bar{z} = \operatorname{Im}(\bar{\omega}_1 \omega_2)$, and the lattice Λ_X of (e) is the crystal lattice of periods (Example 8.61).

8.10 H_1, H^1 and the cup product

This section is the main input of the chapter to Section 4.1 of the paper. The paper works with $H^1(X_0(M^\Sigma), \mathbb{Z}_\ell)$ and states that the cup product is "perfect and alternating" on it and that the Hecke operators are self-adjoint for the cup product composed with w_{M^Σ}; Proposition prop:pullback computes the cup product on $\varphi_E^* H^1(E, \mathbb{Z}_\ell)$. We define H_1 and H^1 of a compact Riemann surface without sheaves ($H^1 := \operatorname{Hom}(H_1, \mathbb{Z})$, with de Rham forms to compute), prove that the cup product is perfect and alternating with Gram matrix $\left(\begin{smallmatrix} 0 & I_g \\ -I_g & 0 \end{smallmatrix}\right)$ in a symplectic basis, and set up pullback, pushforward and the transfer with the projection formula, which is the

cohomological meaning of the degree. The convention box Convention 8.63 says which object is dual to which. Throughout, X and Y are compact Riemann surfaces of genera g_X, g_Y (or g).

Definition 8.56 (first homology)**.** $H_1(X,\mathbb{Z})$ is the abelianisation of the fundamental group $\pi_1(X)$; equivalently, singular homology in degree one. For the reader: an element is represented by a finite formal sum of closed oriented loops, two sums being identified when their difference bounds a (sum of oriented) surface pieces; a loop's class depends only on its free homotopy class. A holomorphic map $\varphi\colon X \to Y$ induces $\varphi_*\colon H_1(X,\mathbb{Z}) \to H_1(Y,\mathbb{Z})$, $[\gamma] \mapsto [\varphi\circ\gamma]$. For an abelian group A, $H_1(X,A) = H_1(X,\mathbb{Z}) \otimes A$; in particular $H_1(X,\mathbb{Z}_\ell) = H_1(X,\mathbb{Z}) \otimes \mathbb{Z}_\ell$ and $H_1(X,\mathbb{Z}/n) = H_1(X,\mathbb{Z})/n$.

Theorem 8.57 (symplectic bases; stated)**.** *Let X have genus g.*

(i) $H_1(X,\mathbb{Z})$ is free of rank $2g$, with a symplectic basis *$a_1,\dots,a_g,b_1,\dots,b_g$: on the model "sphere with g handles", a_j goes around the j-th handle and b_j through it.*

(ii) The intersection pairing $H_1(X,\mathbb{Z}) \times H_1(X,\mathbb{Z}) \to \mathbb{Z}$, which on transverse oriented loops is the signed count of crossings of Convention 8.1(C6), is well defined, bilinear, alternating and perfect, with $a_i \cdot b_j = \delta_{ij}$ and $a_i \cdot a_j = b_i \cdot b_j = 0$.

(iii) Every class in $H_1(X,\mathbb{Z})$ is represented by a sum of loops avoiding any given finite set, and the kernel of $H_1(X\setminus S,\mathbb{Z}) \to H_1(X,\mathbb{Z})$, for a finite set S, is generated by small loops around the points of S.

We do not prove this; see [136, Chapter VIII, Section 1], [70, Section 21], [64, Chapter III, Section 1] and, for (iii), the Mayer-Vietoris sequence in [80, Chapter 2] (all section numbers not verified). In the language of physics, the intersection number is a signed crossing count, like a winding or linking number.

Definition 8.58 (first cohomology)**.** $H^1(X,\mathbb{Z}) = \mathrm{Hom}(H_1(X,\mathbb{Z}),\mathbb{Z})$, and for an abelian group (or ring) A, $H^1(X,A) = \mathrm{Hom}(H_1(X,\mathbb{Z}),A)$. A holomorphic map $\varphi\colon X \to Y$ induces $\varphi^*\colon H^1(Y,A) \to H^1(X,A)$, the transpose of φ_*: $(\varphi^*\xi)(\gamma) = \xi(\varphi_*\gamma)$. A closed 1-form θ defines the class $[\theta] \in H^1(X,\mathbb{C})$, $\gamma \mapsto \int_\gamma \theta$ (well defined by Stokes: the integral over a boundary is zero). $H^2(X,\mathbb{R})$ is the space of smooth 2-forms modulo exact ones, and $H^2(X,\mathbb{Z})$ the subgroup of classes with integral integral.

Proposition 8.59 (cohomology of a compact Riemann surface)**.**

(i) $H^1(X,\mathbb{Z})$ is free of rank $2g$, and $H^1(X,A) = H^1(X,\mathbb{Z}) \otimes A$ for every abelian group A; in particular $H^1(X,\mathbb{Z}_\ell) = H^1(X,\mathbb{Z}) \otimes \mathbb{Z}_\ell$ is free of rank $2g$ over $\mathbb{Z}_\ell$. With the dual basis of a symplectic basis, written $a_1^\vee,\dots,a_g^\vee,b_1^\vee,\dots,b_g^\vee$, $H^1(X,\mathbb{Z}) = \bigoplus \mathbb{Z}a_j^\vee \oplus \bigoplus \mathbb{Z}b_j^\vee$.

(ii) (de Rham; stated.) Every class in $H^1(X,\mathbb{R})$ is $[\theta]$ for a closed real 1-form θ, unique up to an exact form; $H^1(X,\mathbb{Z})$ is the lattice of classes with integral periods. $\int_X\colon H^2(X,\mathbb{R}) \to \mathbb{R}$ is an isomorphism, so $H^2(X,\mathbb{Z}) \simeq \mathbb{Z}$, generated by the class of integral 1; this fixes the isomorphism $H^2(X,\mathbb{Z}) = \mathbb{Z}$.

(iii) (Hodge.) $H^1(X,\mathbb{C}) = H^0(X,\Omega^1) \oplus \overline{H^0(X,\Omega^1)}$: every class is $[\omega+\bar\eta]$ for unique holomorphic ω, η.

(iv) (Stated.) For $g \geq 1$ the universal cover of X is $\mathbb{C}$ or the unit disc, so X is a $K(\pi_1(X),1)$, and $H^1(X,M) = H^1(\pi_1(X),M)$ in the sense of Chapter 16 for every abelian group M with trivial action, compatibly with cup products. This is the bridge to the group cohomology of $\Gamma_0(N)$ used by Diamond, Flach and Guo (Chapter 14).

Proof. (i) $H_1(X,\mathbb{Z}) \simeq \mathbb{Z}^{2g}$ (Theorem 8.57), and $\mathrm{Hom}(\mathbb{Z}^{2g},A) = A^{2g} = \mathrm{Hom}(\mathbb{Z}^{2g},\mathbb{Z}) \otimes A$. The universal coefficient theorem, with H_0 free, identifies this with singular cohomology (stated, [80, Section 3.1]). (ii) is [136, Chapter VIII] and [70, Sections 10 and 19] (not verified); we do not prove it.

(iii) (Sketch, given (ii) and Theorem 8.54.) The map $(\omega,\eta) \mapsto [\omega + \bar{\eta}]$ from $H^0(X,\Omega^1) \oplus H^0(X,\Omega^1)$ to $H^1(X,\mathbb{C})$ is injective: if $\omega + \bar{\eta} = dF$, then $\int_X (\omega+\bar{\eta}) \wedge \bar{\omega} = \int_X d(F\bar{\omega}) = 0$ by Stokes ($\bar{\omega}$ is closed), while $\int_X \bar{\eta} \wedge \bar{\omega} = \overline{\int_X \eta \wedge \omega} = 0$ by Theorem 8.55(a); so $\int_X \omega \wedge \bar{\omega} = 0$ and $\omega = 0$ by Theorem 8.55(b); then $\bar{\eta} = dF$ and the same argument gives $\eta = 0$. Both sides have complex dimension $2g$, by Theorem 8.54 and (i) with (ii). (The proof is complete given the stated inputs; it is labelled a sketch only because de Rham's theorem is.) (iv) We do not prove this; see [80, Section 1.B] (not verified). □

Theorem 8.60 (the cup product)**.** *The* cup product

$$\langle\ ,\ \rangle \colon H^1(X,\mathbb{Z}) \times H^1(X,\mathbb{Z}) \to H^2(X,\mathbb{Z}) = \mathbb{Z}, \qquad \langle \theta,\eta\rangle = \int_X \theta \wedge \eta$$

(de Rham representatives) is well defined, integral, bilinear, alternating and perfect. In the basis dual to a symplectic basis,

$$\langle a_i^\vee, b_j^\vee\rangle = \delta_{ij}, \qquad \langle a_i^\vee, a_j^\vee\rangle = \langle b_i^\vee, b_j^\vee\rangle = 0,$$

so the Gram matrix is $\left(\begin{smallmatrix} 0 & I_g \\ -I_g & 0 \end{smallmatrix}\right)$, of determinant 1*. The map* PD$\colon H^1(X,\mathbb{Z}) \to H_1(X,\mathbb{Z})$ *defined by $\xi(\mathrm{PD}(\theta)) = \langle\theta,\xi\rangle$ for all ξ is an isomorphism (*Poincare duality*) with $\mathrm{PD}(a_j^\vee) = b_j$ and $\mathrm{PD}(b_j^\vee) = -a_j$, and an isometry: $\langle\theta,\eta\rangle = \mathrm{PD}(\theta)\cdot\mathrm{PD}(\eta)$. For every commutative ring R (in particular $\mathbb{Z}_\ell$, $\mathbb{F}_\ell$, $\mathbb{Q}_\ell$, $\mathbb{C}$) the R-bilinear extension to $H^1(X,R)$ is perfect and alternating.*

Proof. Changing θ by dF changes $\int \theta\wedge\eta$ by $\int d(F\eta) = 0$ (Stokes, η closed), so the pairing is well defined; it is bilinear, and alternating because $\theta\wedge\theta = 0$. By Theorem 8.55(c), $\langle\theta,\eta\rangle = \sum_j (\theta(a_j)\eta(b_j) - \theta(b_j)\eta(a_j))$, an integer for integral classes; on the dual basis this gives the displayed values and the Gram matrix, whose determinant is 1. So the pairing is perfect (Chapter 3: perfect iff the Gram determinant is a unit). For PD: $\xi \mapsto \langle\theta,\xi\rangle$ is an element of $\mathrm{Hom}(H^1(X,\mathbb{Z}),\mathbb{Z})$, which is $H_1(X,\mathbb{Z})$ (a free module of finite rank is its double dual); this defines PD, an isomorphism by perfectness. The class b_j has $a_i^\vee(b_j) = 0$ and $b_i^\vee(b_j) = \delta_{ij}$, which are the values $\langle a_j^\vee, a_i^\vee\rangle = 0$ and $\langle a_j^\vee, b_i^\vee\rangle = \delta_{ij}$; so $\mathrm{PD}(a_j^\vee) = b_j$, and likewise $\mathrm{PD}(b_j^\vee) = -a_j$. Then $\mathrm{PD}(a_i^\vee)\cdot\mathrm{PD}(b_j^\vee) = b_i\cdot(-a_j) = a_j\cdot b_i = \delta_{ij} = \langle a_i^\vee, b_j^\vee\rangle$, and the other basis pairs give 0 on both sides; by bilinearity PD is an isometry. Base change: the Gram matrix over R is the image of the integral one, of determinant 1 (Chapter 3), and $\langle x,x\rangle = 0$ holds for $x \in H^1(X,R)$ because it holds on a basis and $\langle x,y\rangle = -\langle y,x\rangle$. □

The input that is only stated is the existence of a symplectic basis and the bilinear identity of Theorem 8.55(c); perfectness is Poincare duality for surfaces, which in general is [80, Section 3.3]. Over $\mathbb{R}$ nondegeneracy also follows from positivity: by Proposition 8.59(iii), $\langle[\omega],[\bar{\omega}]\rangle \neq 0$ for $\omega \neq 0$.

Example 8.61 (the torus)**.** Let $X = \mathbb{C}/\Lambda$, $\Lambda = \mathbb{Z}\omega_1 + \mathbb{Z}\omega_2$ with $\operatorname{Im}(\omega_2/\omega_1) > 0$, and real coordinates $z = s\omega_1 + t\omega_2$, $s, t \in \mathbb{R}/\mathbb{Z}$. From $dz = \omega_1 ds + \omega_2 dt$ one computes

$$dz \wedge d\bar{z} = (\omega_1 ds + \omega_2 dt) \wedge (\bar{\omega}_1 ds + \bar{\omega}_2 dt) = (\omega_1\bar{\omega}_2 - \omega_2\bar{\omega}_1)\, ds \wedge dt = -2i \operatorname{Im}(\bar{\omega}_1\omega_2)\, ds \wedge dt,$$

so $dx \wedge dy = \frac{i}{2} dz \wedge d\bar{z} = \operatorname{Im}(\bar{\omega}_1\omega_2)\, ds \wedge dt$, and $\operatorname{Im}(\bar{\omega}_1\omega_2) = |\omega_1|^2 \operatorname{Im}(\omega_2/\omega_1) > 0$ (as $\bar{\omega}_1\omega_2 = |\omega_1|^2\, \omega_2/\omega_1$); so $ds \wedge dt$ is positive and $\int_X ds \wedge dt = 1$ (the unit square in (s,t) is a fundamental domain).

(a) $H_1(X, \mathbb{Z}) = \Lambda$ (a path from 0 to λ in $\mathbb{C}$ projects to a loop), with a the image of $[0, \omega_1]$ and b that of $[0, \omega_2]$. They meet only at 0, with tangents ∂_s, ∂_t, a positive basis: $a \cdot b = +1$.

(b) $H^1(X, \mathbb{Z})$ has basis $[ds]$, $[dt]$, dual to a, b; $\langle ds, dt\rangle = \int ds \wedge dt = 1$; $\mathrm{PD}(ds) = b$, $\mathrm{PD}(dt) = -a$; and Theorem 8.55(c) reads $1 = A(ds)B(dt) - B(ds)A(dt) = 1 \cdot 1 - 0 \cdot 0$.

(c) The holomorphic form $dz = \omega_1 ds + \omega_2 dt$ has periods $A = \omega_1$, $B = \omega_2$, and $\frac{i}{2}\int dz \wedge d\bar{z} = \operatorname{Im}(\bar{\omega}_1\omega_2)$ is the area of the period parallelogram: Theorem 8.55(b), (d). For $\Lambda = \mathbb{Z} + \tau\mathbb{Z}$ the inequality of (d) is $\operatorname{Im}\tau > 0$.

(d) $[-1]\colon z \mapsto -z$ acts by -1 on H_1 and H^1, and is an isometry: $\langle -x, -y\rangle = \langle x, y\rangle$. Multiplication by an integer $m \neq 0$ acts by m on H_1 and on H^1 (it pulls ds back to $m\, ds$), and by m^2 on H^2 (it pulls $ds \wedge dt$ back to $m^2 ds \wedge dt$), so it has degree m^2 (Proposition 8.62(iv)); directly, the fibre over 0 is $\frac{1}{m}\Lambda/\Lambda$, with m^2 points, all unramified.

In the language of physics, Λ is a crystal lattice, $H^1(X, \mathbb{Z}) = \operatorname{Hom}(\Lambda, \mathbb{Z})$ its reciprocal lattice, and $ds \wedge dt$ the normalised volume form of the periodic box.

Proposition 8.62 (pullback, pushforward, transfer; the projection formula)**.** *Let $\varphi\colon X \to Y$ be a nonconstant holomorphic map of compact Riemann surfaces, $n = \deg\varphi$, $B \subseteq Y$ its finite set of branch points, $Y' = Y \setminus B$, $X' = \varphi^{-1}(Y')$.*

(i) On de Rham classes $\varphi^*[\theta] = [\varphi^*\theta]$: $\int_\gamma \varphi^*\theta = \int_{\varphi_*\gamma} \theta$ (change of variables). $\varphi\colon X' \to Y'$ is an n-sheeted covering map, locally the disjoint union of n biholomorphisms, each orientation-preserving.

(ii) (Transfer.) There is a unique homomorphism $\varphi^!\colon H_1(Y, \mathbb{Z}) \to H_1(X, \mathbb{Z})$ sending the class of a loop γ in Y' to the class of $\varphi^{-1}(\gamma)$, the sum of the closed loops formed by the n lifts of γ. It satisfies $\varphi_*\varphi^! = n$.

(iii) (Pushforward on H^1.) Define $\varphi_*\colon H^1(X, A) \to H^1(Y, A)$ as the transpose of $\varphi^!$: $(\varphi_*\eta)(\gamma) = \eta(\varphi^!\gamma)$. Every class in $H^1(X, \mathbb{R})$ is represented by a closed form θ vanishing near $\varphi^{-1}(B)$, and then $\varphi_*[\theta]$ is represented by the trace $\operatorname{Tr}\theta$: on Y', $\operatorname{Tr}\theta = \sum_i s_i^*\theta$ over the local sections $s_1, \dots, s_n$ of φ, extended by 0 near B.

(iv) (Projection formula.) For $\eta \in H^1(X, \mathbb{Z})$ and $\xi, \xi' \in H^1(Y, \mathbb{Z})$:

$$\langle \varphi_*\eta, \xi\rangle_Y = \langle \eta, \varphi^*\xi\rangle_X, \qquad \varphi_*\varphi^* = n \text{ on } H^1(Y, \mathbb{Z}), \qquad \langle \varphi^*\xi, \varphi^*\xi'\rangle_X = n\, \langle \xi, \xi'\rangle_Y,$$

and $\int_X \varphi^*\rho = n \int_Y \rho$ for every smooth 2-form ρ on Y: φ^* is multiplication by n on $H^2(\cdot, \mathbb{Z}) = \mathbb{Z}$. In particular φ^* is injective on $H^1(Y, \mathbb{Z})$ and $\varphi_*\colon H_1(X, \mathbb{Z}) \to H_1(Y, \mathbb{Z})$ has finite cokernel, killed by n.

(v) $(\psi\circ\varphi)_* = \psi_*\varphi_*$, $(\psi\circ\varphi)^* = \varphi^*\psi^*$, $(\psi\circ\varphi)^! = \varphi^!\psi^!$*; for an automorphism* w, $w^! = (w^{-1})_*$ *and* $w_* = (w^{-1})^*$ *on* H^1.

Proof. (i) The integral identity is the change of variables formula for line integrals (on each chart piece of γ). By Theorem 8.48(c), (d), every point of Y' has exactly n preimages, each of multiplicity one, at which φ is a local biholomorphism; the proof of Theorem 8.48(c) gives a neighbourhood V with $\varphi^{-1}(V)$ a disjoint union of n open sets mapped biholomorphically onto V. Orientation is preserved by Theorem 8.48(e).

(ii) (Sketch.) By Theorem 8.57(iii), classes in $H_1(Y,\mathbb{Z})$ are represented by loops in Y'. For a covering, the preimage of a loop is a union of closed loops covering it n times in total, and the covering transfer $H_1(Y',\mathbb{Z})\to H_1(X',\mathbb{Z})$ is well defined ([80, Section 3.G], not verified). By Theorem 8.57(iii), the kernel of $H_1(Y',\mathbb{Z})\to H_1(Y,\mathbb{Z})$ is generated by small loops around the points of B; the preimage of such a loop is a sum of small loops around the points of $\varphi^{-1}(B)$ (by the normal form $w=z^e$, a loop around Q lifts to loops around the points over Q), which are null-homologous in X. So the transfer descends to $\varphi^!$. Pushing forward the n lifts of γ gives $n\gamma$, so $\varphi_*\varphi^! = n$.

(iii) Let θ be a closed form on X and $P\in\varphi^{-1}(B)$. On a coordinate disc U around P, $\theta = dF$ for a smooth function F (Poincare lemma on a disc). With ρ a smooth function equal to 1 near P and supported in U, $\theta - d(\rho F)$ is in the same class and vanishes near P. Doing this at the finitely many points of $\varphi^{-1}(B)$ gives a representative vanishing near $\varphi^{-1}(B)$. For such θ, $\operatorname{Tr}\theta$ is smooth and closed on Y' (locally a finite sum of pullbacks of closed forms by biholomorphisms) and vanishes near B, so it extends by 0 to a closed form on Y. For a loop γ in Y', $\int_\gamma \operatorname{Tr}\theta = \sum_i \int_{s_i\circ\gamma}\theta = \int_{\varphi^{-1}(\gamma)}\theta$, which is $[\theta](\varphi^!\gamma)$; as loops in Y' represent all of $H_1(Y,\mathbb{Z})$, $[\operatorname{Tr}\theta] = \varphi_*[\theta]$.

(iv) For a 2-form ψ on X, let $\operatorname{Tr}\psi = \sum_i s_i^*\psi$ on Y'. On V as in (i), $\int_V \operatorname{Tr}\psi = \sum_i \int_{s_i(V)}\psi = \int_{\varphi^{-1}(V)}\psi$ (each s_i is an orientation-preserving diffeomorphism onto its image); covering Y' by countably many such V and using a partition of unity, $\int_{Y'}\operatorname{Tr}\psi = \int_{X'}\psi$. Finite sets have measure zero, so $\int_{X'} = \int_X$ and $\int_{Y'} = \int_Y$ for smooth forms. Now take θ as in (iii) representing η, and ξ represented by a closed form, also written ξ. On Y', $\operatorname{Tr}(\theta)\wedge\xi = \sum_i s_i^*\theta\wedge s_i^*\varphi^*\xi = \operatorname{Tr}(\theta\wedge\varphi^*\xi)$, since $\varphi\circ s_i = \mathrm{id}$. Hence $\langle\varphi_*\eta,\xi\rangle = \int_Y \operatorname{Tr}(\theta)\wedge\xi = \int_X \theta\wedge\varphi^*\xi = \langle\eta,\varphi^*\xi\rangle$. For a 2-form ρ on Y, $\operatorname{Tr}(\varphi^*\rho) = n\rho$ on Y', so $\int_X\varphi^*\rho = n\int_Y\rho$. Choosing the representative ξ of a class in $H^1(Y)$ to vanish near B (as in (iii), with Y in place of X), $\varphi^*\xi$ vanishes near $\varphi^{-1}(B)$ and $\operatorname{Tr}(\varphi^*\xi) = n\xi$; so $\varphi_*\varphi^* = n$ by (iii). Then $\langle\varphi^*\xi,\varphi^*\xi'\rangle = \langle\varphi_*\varphi^*\xi,\xi'\rangle = n\langle\xi,\xi'\rangle$ (alternatively, $\int_X\varphi^*(\xi\wedge\xi') = n\int_Y\xi\wedge\xi'$). Since $H^1(Y,\mathbb{Z})$ is torsion-free and $\varphi_*\varphi^* = n$, φ^* is injective; dually $\varphi_*\varphi^! = n$ on H_1 shows that $nH_1(Y,\mathbb{Z})\subseteq\varphi_*H_1(X,\mathbb{Z})$.

(v) Functoriality of φ_* on loops is clear, φ^* is its transpose, and $\varphi^!$ is compatible with composition on loops avoiding the branch points of both maps. An automorphism w is unramified of degree one, so $w^{-1}(\gamma) = (w^{-1})\circ\gamma$; transposing gives the last statement. □

The transfer is easiest to see on the torus $X = Y = \mathbb{C}/\Lambda$ with $\varphi = [m]$, $z\mapsto mz$, of degree $n = m^2$ (Example 8.61(d)), which is unramified, so no loop has to be moved. The loop a, the image of $s\mapsto s\omega_1$, $s\in[0,1]$, has the m^2 lifts $s\mapsto(s\omega_1+\lambda)/m$, one for each class $\lambda\in\Lambda/m\Lambda$. The lift indexed by λ ends where the lift indexed by $\lambda+\omega_1$ begins, so the lifts link up in chains of m (indexed by $\lambda,\lambda+\omega_1,\dots,\lambda+(m-1)\omega_1$), each chain forming a closed loop from λ/m to $\lambda/m+\omega_1$, whose class in $H_1=\Lambda$ is ω_1, that is a. There are $m^2/m = m$ such loops, so $\varphi^!a = m\,a$, and likewise $\varphi^!b = m\,b$. As $\varphi_* = m$ on H_1, $\varphi_*\varphi^! = m^2 = n$, as (ii) says; on H^1, $\varphi^* = m$ and φ_* (the transpose of $\varphi^!$) is also m, and $\varphi_*\varphi^* = m^2$ as in (iv). For a general φ the transfer is not a

multiple of the identity, and it is the transfer, not φ_*, that is injective on H_1.

Convention 8.63 (which is dual to which)**.**

(a) *Covariant objects*: $H_1(X,\mathbb{Z})$, the period lattice Λ_X, the Jacobian $J(X) = H^0(X,\Omega^1)^\vee/\Lambda_X$, its torsion $J[n] = H_1(X,\mathbb{Z}/n)$ and its Tate module $T_\ell J = H_1(X,\mathbb{Z}_\ell)$ (Section 8.11). A morphism φ acts by φ_*, a correspondence $\mathcal{C} = (C,\alpha,\beta)$ by $\mathcal{C}_* = \beta_*\alpha^!$ (Proposition 8.80).

(b) *Contravariant objects*: $H^1(X,\mathbb{Z}) = \mathrm{Hom}(H_1,\mathbb{Z})$, $H^1(X,\mathbb{Z}_\ell) = \mathrm{Hom}_{\mathbb{Z}_\ell}(T_\ell J,\mathbb{Z}_\ell)$, $H^0(X,\Omega^1)$. A morphism acts by φ^*, a correspondence by $\mathcal{C}^* = \alpha_*\beta^*$, and $\mathcal{C}^*$ is the transpose of $\mathcal{C}_*$ for the evaluation pairing.

(c) The two sides are identified by Poincare duality (Theorem 8.60), an isometry for the cup product and the intersection pairing, which turns $\mathcal{C}^*$ into $(\mathcal{C}^t)_*$ (Theorem 8.81(c)); it is canonical up to the global orientation sign.

(d) With Galois action (Theorem 8.74): $H^1_{\text{et}} = (T_\ell J)^\vee \simeq T_\ell J(-1)$. For an elliptic curve, $V = V_\ell E$ (the paper's V) has determinant χ_ℓ, and $H^1(E,\mathbb{Q}_\ell) = V^\vee \simeq V(-1)$ has determinant χ_ℓ^{-1}; $\mathrm{ad}^0 V$ is the same for V, $V^\vee$ and $V(n)$ (Chapter 4).

(e) Frobenius (Convention 8.1(C7)): the arithmetic Frobenius on $T_\ell J$ and the geometric Frobenius on H^1 have the same characteristic polynomial $P(T)$, with $\#C(\mathbb{F}_q) = q + 1 - \mathrm{tr}$.

In the paper 8.64. Section 4.1 of the paper (sec:dfg): the pairing $\hat{\delta}_!$ "is perfect and alternating on $H^1(X_0(M^\Sigma),\mathbb{Z}_\ell)$", being $\frac{1}{2}$ times the cup product composed with w_{M^Σ} on classes from $X_0(M^\Sigma)$. The cup product is perfect and alternating on $H^1(X_0(M^\Sigma),\mathbb{Z}_\ell)$ by Theorem 8.60 with $R = \mathbb{Z}_\ell$; the factor $\frac{1}{2}$ is a unit for odd ℓ; composing with the automorphism $w^*_{M^\Sigma}$ preserves perfectness, and alternation needs w^* to be an isometric involution (Corollary 8.82). Proposition prop:pullback: "$\varphi^*(a\cup b) = \varphi^*a\cup\varphi^*b$ and φ^* multiplies the fundamental class of H^2 by $\deg\varphi_E$; so $\langle\varphi^*a,\varphi^*b\rangle_{X_0(N)} = \deg\varphi_E\,\langle a,b\rangle_E$, the projection formula" is Proposition 8.62(iv); "The cup product on $H^1(E,\mathbb{Z})$ is unimodular" is Theorem 8.60 for $g = 1$ (Example 8.61).

8.11 The Jacobian: Pic^0, complex torus, abelian variety; torsion and Tate modules

The Jacobian $J(X)$ of a curve is Pic^0, made into a complex torus by integrating holomorphic forms and into an abelian variety by a theorem. The paper uses it three times: the modular parametrisation factors as $X_0(N)\to J_0(N)\to E$, and optimality of E means that the kernel of $J_0(N)\to E$ is connected (Section 1, Proposition prop:pullback); Remark rem:free speaks of $J_0(N)[\mathfrak{m}]$ and of the Tate module of $J_0(N)$; and the paragraph after Proposition prop:pullback identifies the lattice $M_{f,\lambda}$ with $H^1(E,\mathbb{Z}_\ell) = \mathrm{Hom}(T_\ell E,\mathbb{Z}_\ell)\simeq T_\ell E(-1)$. This section proves the facts behind these sentences for a general curve, in particular Proposition 8.70, which turns "connected kernel" into "saturated image of φ^* on H^1" and computes the cup product on that image.

Definition 8.65 (the Jacobian)**.** For a smooth projective curve C over k, $J(C)(\bar{k}) = \mathrm{Pic}^0(C)$, with the action of G_k of Proposition 8.24(ii). For a compact Riemann surface X of genus $g\geq 1$, the *analytic Jacobian* is $J_{\text{an}}(X) = H^0(X,\Omega^1)^\vee/\Lambda_X$, with Λ_X the period lattice of Theorem 8.55(e), a complex torus of dimension g. Examples: $J(\mathbb{P}^1) = 0$ (Proposition 8.24(i)); for $g = 1$ and $O\in C(k)$, $J(C)\simeq C$ by Proposition 8.34.

Theorem 8.66 (Abel-Jacobi). *Let X be a compact Riemann surface of genus $g \geq 1$.*

(i) The Abel-Jacobi map $\mathrm{AJ}\colon \mathrm{Div}^0(X) \to J_{\mathrm{an}}(X)$, $\sum_i((P_i)-(Q_i)) \mapsto (\omega \mapsto \sum_i \int_{Q_i}^{P_i} \omega) \bmod \Lambda_X$, *is a well-defined homomorphism.*

(ii) (Abel; stated.) $\ker \mathrm{AJ} = \mathrm{Prin}(X)$. *(Jacobi inversion; stated.)* AJ *is surjective. Hence* $\mathrm{AJ}\colon \mathrm{Pic}^0(X) \to J_{\mathrm{an}}(X)$ *is an isomorphism.*

(iii) For a base point P_0, $\iota\colon X \to J_{\mathrm{an}}(X)$, $P \mapsto \mathrm{AJ}((P)-(P_0))$, is holomorphic and injective, and $\iota_*\colon H_1(X,\mathbb{Z}) \to H_1(J_{\mathrm{an}}(X),\mathbb{Z}) = \Lambda_X$ is the period isomorphism of Theorem 8.55(e). For $g = 1$, $\iota\colon X \to \mathbb{C}/\Lambda_X$ is an isomorphism.

Proof. (i) Two paths from Q_i to P_i differ by a closed loop, so the integrals differ by a period, an element of Λ_X; the map is additive. (ii) We do not prove this; see [136, Chapter VIII], [70, Sections 20 and 21] and [75, Chapter 2, Section 2] (not verified). The "only if" half of Abel's theorem ($\mathrm{AJ}(\operatorname{div} f) = 0$) is a trace computation: for nonconstant $f\colon X \to \mathbb{P}^1$, $\operatorname{div} f = f^*((0)-(\infty))$, and as in the proof of Proposition 8.68(iii), $\mathrm{AJ}(\operatorname{div} f)(\omega) \equiv \int_\infty^0 \mathrm{Tr}_f\,\omega$ modulo periods; $\mathrm{Tr}_f\,\omega$ is a holomorphic form on $\mathbb{P}^1$, hence 0 (Proposition 8.26(iv)). (iii) In a chart near P_1, $\iota(P) = \iota(P_1) + (\omega \mapsto \int_{P_1}^P \omega)$, and $P \mapsto \int_{P_1}^P \omega$ is a primitive of a holomorphic function, so ι is holomorphic. If $\iota(P) = \iota(Q)$ then $\mathrm{AJ}((P)-(Q)) = 0$, so $(P) \sim (Q)$ by Abel's theorem, and $P = Q$ since $g \geq 1$ (Corollary 8.30(d)). For a loop γ based at P_0, the path $t \mapsto (\omega \mapsto \int_{\gamma|[0,t]} \omega)$ in $H^0(X,\Omega^1)^\vee$ lifts $\iota \circ \gamma$ and ends at the period vector of γ; and $H_1(V/\Lambda,\mathbb{Z}) = \Lambda$ for a torus, by the endpoint of the lift of a loop through 0 (as in Example 8.61). So ι_* is the period map. For $g = 1$, ι is an injective holomorphic map between compact Riemann surfaces, hence surjective and of degree one (Theorem 8.48), hence an isomorphism. This is the analytic form of Proposition 8.34; Chapter 9 makes it explicit with the Weierstrass function $\wp$. □

Theorem 8.67 (the Jacobian variety; stated). *Let C be a smooth projective curve of genus $g \geq 1$ over k.*

(i) There is an abelian variety $J = \mathrm{Jac}(C)$ over k (a smooth projective connected group variety) of dimension g with $J(\bar{k}) = \mathrm{Pic}^0(C)$ compatibly with G_k; and $J(L) \supseteq \mathrm{Div}^0_L(C)/\operatorname{div}(L(C)^\times)$, with equality when $C(L) \neq \emptyset$ (Proposition 8.24(iii)).

(ii) Over $\mathbb{C}$, $J(\mathbb{C}) \simeq J_{\mathrm{an}}(C(\mathbb{C}))$ as complex Lie groups, via AJ*; the torus is algebraic because the cup product, with the positivity of Theorem 8.55, is a Riemann form on Λ_X (Riemann, Lefschetz).*

(iii) (Universal property.) For $P_0 \in C(k)$, $\iota\colon C \to J$, $P \mapsto [(P)-(P_0)]$, is a closed immersion defined over k, and every morphism $C \to A$ to an abelian variety over k sending P_0 to 0 factors uniquely as $h \circ \iota$ with $h\colon J \to A$ a homomorphism over k.

(iv) (Mordell-Weil.) $J(K)$ is finitely generated for a number field K; in particular $J(K)_{\mathrm{tors}}$ is finite.

We do not prove this; see [130, Sections 1 to 6], [129], [138, Section 24] and [15, Chapter 9] (section numbers not verified).

Proposition 8.68 (functoriality of the Jacobian). *Let $\varphi\colon X \to Y$ be a nonconstant morphism of smooth projective curves, $n = \deg \varphi$.*

(i) $\varphi_*\colon J(X)\to J(Y)$ *(pushforward of divisor classes, "Albanese") and* $\varphi^*\colon J(Y)\to J(X)$ *(pullback, "Picard") are homomorphisms,* G_k*-equivariant if* φ *is defined over* k*, with* $\varphi_*\varphi^* = [n]$ *on* $J(Y)$*.*

(ii) Over $\mathbb{C}$*, under* AJ*,* φ_* *is induced by the transpose* $(\varphi^*)^\vee\colon H^0(X,\Omega^1)^\vee\to H^0(Y,\Omega^1)^\vee$ *of the pullback of forms, and on lattices by* $\varphi_*\colon H_1(X,\mathbb{Z})\to H_1(Y,\mathbb{Z})$*.*

(iii) Over $\mathbb{C}$*,* φ^* *on* J *is induced by the transpose of the trace* $\operatorname{Tr}\colon H^0(X,\Omega^1)\to H^0(Y,\Omega^1)$ *and on lattices by the transfer* $\varphi^!$*.*

(iv) If $Y = E$ *has genus one, with origin* $O=\varphi(P_0)$ *and* $J(E)=E$ *(Proposition 8.34), then* $\varphi = \varphi_*\circ\iota_X$ *with* $\iota_X(P) = [(P)-(P_0)]$*, and* $\varphi_*\circ\varphi^*\colon E\to J(X)\to E$ *is multiplication by* n*.*

Proof. (i) is Corollary 8.39(iii) and Proposition 8.18(iii). (ii) For $D=\sum((P_i)-(Q_i))$ and paths c_i from Q_i to P_i, $\mathrm{AJ}_Y(\varphi_*D)(\omega) = \sum\int_{\varphi\circ c_i}\omega = \sum\int_{c_i}\varphi^*\omega = \mathrm{AJ}_X(D)(\varphi^*\omega)$, by change of variables (Proposition 8.62(i)); on closed loops this is the statement about lattices. (iii) (Sketch.) For a holomorphic form ω on X, $\operatorname{Tr}\omega = \sum s_i^*\omega$ is holomorphic on Y', and it extends holomorphically over each branch point: in the normal form $w=z^e$ at a point over it, the e local sections are $z=\zeta_e^k w^{1/e}$, and for $\omega=\sum_m c_m z^m\,dz$ one finds $\sum_k s_k^*\omega = \sum_{e\mid m+1} c_m w^{(m+1)/e-1}\,dw$, with nonnegative exponents. For $D=(P)-(Q)$ and a path c from Q to P through Y' except at its ends, the n lifts of c run from the points of $\varphi^*(Q)$ to those of $\varphi^*(P)$, with multiplicities e_φ, so $\mathrm{AJ}_X(\varphi^*D)(\omega)=\int_c\operatorname{Tr}\omega = \mathrm{AJ}_Y(D)(\operatorname{Tr}\omega)$. On loops this is $\varphi^!$. See [130, Section 6] (not verified). (iv) $\varphi_*\iota_X(P) = [(\varphi(P))-(O)]$, which is $\varphi(P)$ under κ^{-1} of Proposition 8.34; and $\varphi_*\varphi^*=[n]$ by (i). □

This is the universal property of Theorem 8.67(iii) made explicit: φ factors through $J(X)$, and for $X=X_0(N)$, $P_0=\infty$, the factor $\varphi_*\colon J_0(N)\to E$ is "the map $J_0(N)\to E$ induced by φ" of the paper. E is its own dual, so the statement that $E^\vee\to J_0(N)\to E$ is multiplication by $\deg\varphi_E$ (Chapter 14) is (iv).

Lemma 8.69 (homomorphisms of complex tori)**.** *Let* V*,* W *be finite-dimensional complex vector spaces with lattices* $\Lambda\subset V$*,* $M\subset W$*.*

(a) Let $A\colon V\to W$ *be* $\mathbb{C}$*-linear and surjective with* $A(\Lambda)\subseteq M$*, and* $\pi\colon V/\Lambda\to W/M$ *the induced homomorphism. Then* π *is surjective,* $A(\Lambda)$ *has finite index in* M*, the identity component of* $\ker\pi$ *is* $(\ker A+\Lambda)/\Lambda$*, and*

$$\pi_0(\ker\pi) = \ker\pi/(\ker\pi)^0 \;\simeq\; M/A(\Lambda) = \operatorname{coker}\bigl(H_1(\pi)\bigr).$$

(b) Let $B\colon W\to V$ *be* $\mathbb{C}$*-linear and injective with* $B(M)\subseteq\Lambda$*, and* $\beta\colon W/M\to V/\Lambda$ *the induced homomorphism. Then* $\ker\beta\simeq(\Lambda\cap B(W))/B(M) = \operatorname{sat}(B(M))/B(M)$*, the saturation being taken in* Λ*; so* β *is injective iff* $B(M)$ *is saturated in* Λ*.*

(c) A holomorphic map $\psi\colon\mathbb{C}/\Lambda\to\mathbb{C}/\Lambda'$ *with* $\psi(0)=0$ *is* $z\mapsto cz$ *for a* $c\in\mathbb{C}$ *with* $c\Lambda\subseteq\Lambda'$*; if* $c\neq 0$*, it is unramified of degree* $[\Lambda':c\Lambda]$*, and* $\psi_*\colon H_1=\Lambda\to H_1=\Lambda'$ *is the inclusion* $c\Lambda\subseteq\Lambda'$ *(after multiplication by* c*).*

Proof. (a) π is surjective because A is. Λ spans V over $\mathbb{R}$, so $A(\Lambda)$ spans W over $\mathbb{R}$; it is a subgroup of the lattice M of full rank, so of finite index. Now $\ker\pi = A^{-1}(M)/\Lambda$. The map A

induces $A^{-1}(M)/(\ker A+\Lambda)\to M/A(\Lambda)$; it is surjective (every $m\in M$ is $A(v)$ for some v, and $v\in A^{-1}(M)$) and injective (if $A(v)=A(\lambda)$ with $\lambda\in\Lambda$ then $v\in\lambda+\ker A$). So $H=(\ker A+\Lambda)/\Lambda$ has finite index in $\ker\pi$. H is connected, as the image of the vector space $\ker A$. H is closed: $\ker A+\Lambda=A^{-1}(A(\Lambda))$, and $A(\Lambda)$ is discrete, hence closed, in W. So $\ker\pi$ is a finite disjoint union of closed cosets of H, each therefore open in $\ker\pi$, and H is the identity component. Finally $H_1(V/\Lambda,\mathbb{Z})=\Lambda$ and $H_1(\pi)=A|_\Lambda$, as in the proof of Theorem 8.66(iii). (b) $\ker\beta=B^{-1}(\Lambda)/M$, and B maps it isomorphically onto $(\Lambda\cap B(W))/B(M)$. Since $B(M)$ spans the real space $B(W)$, $\Lambda\cap B(W)$ is the intersection of Λ with the real span of $B(M)$, which is the saturation (Chapter 3). (c) ψ lifts to a holomorphic $\tilde\psi\colon\mathbb{C}\to\mathbb{C}$ with $\tilde\psi(0)=0$ (the plane is simply connected). For $\lambda\in\Lambda$, $\tilde\psi(z+\lambda)-\tilde\psi(z)$ is a continuous function with values in the discrete Λ', hence constant; so $\tilde\psi'$ is Λ-periodic and entire, hence bounded and constant (Liouville), and $\tilde\psi(z)=cz$ with $c\Lambda\subseteq\Lambda'$. If $c\neq0$, ψ is a local biholomorphism, so unramified, and its fibre over 0 is $c^{-1}\Lambda'/\Lambda\simeq\Lambda'/c\Lambda$; its degree is the order of the fibre (Theorem 8.48(c)). The last claim is the lift of loops. □

Proposition 8.70 (the degree and the cup product; saturation)**.** *Let $\varphi\colon X\to Y$ be a nonconstant holomorphic map of compact Riemann surfaces of genus ≥1, $n=\deg\varphi$.*

(i) $\langle\varphi^*x,\varphi^*y\rangle_X=n\,\langle x,y\rangle_Y$ *for $x,y\in H^1(Y,\mathbb{Z})$.*

(ii) $\varphi_*\varphi^*=n$ *on $H^1(Y,\mathbb{Z})$, $\varphi_*\varphi^!=n$ on $H_1(Y,\mathbb{Z})$ and $\varphi_*\varphi^*=[n]$ on $J(Y)$. Moreover* $\mathrm{PD}_X\circ\varphi^*=\varphi^!\circ\mathrm{PD}_Y$.

(iii) The following are equivalent: (a) $\varphi^*H^1(Y,\mathbb{Z})$ is saturated in $H^1(X,\mathbb{Z})$; (b) $\varphi_*\colon H_1(X,\mathbb{Z})\to H_1(Y,\mathbb{Z})$ is surjective; (c) $\ker(\varphi_*\colon J(X)\to J(Y))$ is connected; (d) $\varphi^*\colon J(Y)\to J(X)$ is injective. More precisely

$$\begin{aligned}[\mathrm{sat}(\varphi^*H^1(Y,\mathbb{Z})):\varphi^*H^1(Y,\mathbb{Z})]&=\#\operatorname{coker}(\varphi_*\colon H_1(X,\mathbb{Z})\to H_1(Y,\mathbb{Z}))\\&=\#\pi_0(\ker(\varphi_*\colon J(X)\to J(Y)))\\&=\#\ker(\varphi^*\colon J(Y)\to J(X)),\end{aligned}$$

a divisor of n^{2g_Y}.

(iv) Let $Y=E$ have genus one and $M=\varphi^*H^1(E,\mathbb{Z})$. The cup product on M has ideal of values $n\mathbb{Z}$ and Gram determinant n^2. If (iii) holds, $[H^1(X,\mathbb{Z}):M\oplus M^\perp]=n^2$, and for every prime ℓ, $[H^1(X,\mathbb{Z}_\ell):(M\otimes\mathbb{Z}_\ell)\oplus(M\otimes\mathbb{Z}_\ell)^\perp]=\ell^{2v_\ell(n)}$. In general, with $m_0=\#\pi_0(\ker(J(X)\to E))$, m_0 divides n and the cup product on $\mathrm{sat}(M)$ has ideal of values $(n/m_0)\mathbb{Z}$.

(v) (Isogenies.) Let $Y=E$, $\psi\colon E\to E'$ an isogeny of degree m (a nonconstant holomorphic map of genus-one surfaces with $\psi(O)=O'$) and $\varphi'=\psi\circ\varphi$. Then $(\varphi')^*H^1(E',\mathbb{Z})$ has index m in $\varphi^*H^1(E,\mathbb{Z})$. Hence if $\varphi^*H^1(E,\mathbb{Z})$ is saturated and $m>1$, then $(\varphi')^*H^1(E',\mathbb{Z})$ is not.

Proof. (i) and the first two identities of (ii) are Proposition 8.62(ii), (iv); the third is Proposition 8.68(i). For the last, let $\xi\in H^1(Y,\mathbb{Z})$ and $\eta\in H^1(X,\mathbb{Z})$. Then $\eta(\mathrm{PD}_X\,\varphi^*\xi)=\langle\varphi^*\xi,\eta\rangle_X$, while $\eta(\varphi^!\,\mathrm{PD}_Y\,\xi)=(\varphi_*\eta)(\mathrm{PD}_Y\,\xi)=\langle\xi,\varphi_*\eta\rangle_Y=-\langle\varphi_*\eta,\xi\rangle_Y=-\langle\eta,\varphi^*\xi\rangle_X=\langle\varphi^*\xi,\eta\rangle_X$, by the projection formula and alternation.

(iii) Put $L=H_1(X,\mathbb{Z})$, $L'=H_1(Y,\mathbb{Z})$, $u=\varphi_*\colon L\to L'$. Its cokernel Q is finite and killed by n (Proposition 8.62(iv)). By the Smith normal form (Chapter 3) there are bases of L and

L' in which u is $(D \mid 0)$ with $D = \operatorname{diag}(d_1, \dots, d_r)$, $r = 2g_Y$, all $d_i \neq 0$, and $Q \simeq \bigoplus \mathbb{Z}/d_i$. In the dual bases $\varphi^* = u^{\mathsf{T}} = \binom{D}{0}$, whose image $\bigoplus d_i\mathbb{Z} \oplus 0$ has saturation $\mathbb{Z}^r \oplus 0$, of index $\prod d_i = \#Q$. This gives the first equality and (a)⇔(b). By Proposition 8.68(ii), φ_* on J is the map of Lemma 8.69(a) with $A = (\varphi^*)^\vee$, surjective because φ^* is injective on holomorphic forms (φ is a local biholomorphism off a finite set), and with $H_1(\varphi_*) = u$; so $\pi_0(\ker) \simeq \operatorname{coker} u$, which is the second equality and (b)⇔(c). By Proposition 8.68(iii) (sketched), φ^* on J is the map of Lemma 8.69(b) with lattice map $\varphi^!$ (injective, as $\varphi_*\varphi^! = n$); so $\#\ker(\varphi^*)$ is the index of $\varphi^! H_1(Y,\mathbb{Z})$ in its saturation in $H_1(X,\mathbb{Z})$. Poincare duality is an isomorphism carrying $\varphi^* H^1(Y,\mathbb{Z})$ to $\varphi^! H_1(Y,\mathbb{Z})$, by (ii), so this index is the first term. Hence the last equality and (a)⇔(d). As $nL' \subseteq u(L)$, $\#Q$ divides n^{2g_Y}.

(iv) The cup product on $H^1(E,\mathbb{Z})$ is perfect and alternating of rank two, so its ideal of values is $\mathbb{Z}$ (Chapter 3: a rank-two alternating form with Gram matrix $\left(\begin{smallmatrix} 0 & a \\ -a & 0 \end{smallmatrix}\right)$ has ideal of values $a\mathbb{Z}$ and determinant a^2). By (i) and the injectivity of φ^*, the cup product on M is n times a unimodular alternating form: ideal of values $n\mathbb{Z}$, Gram determinant n^2. If M is saturated, then $M \otimes \mathbb{Z}_\ell$ is saturated in $H^1(X,\mathbb{Z}_\ell)$, the cup product is perfect there (Theorem 8.60), and the theorem on Gram determinants of saturated sublattices (Chapter 3) gives $[H^1(X,\mathbb{Z}_\ell) : (M \otimes \mathbb{Z}_\ell) \oplus (M \otimes \mathbb{Z}_\ell)^\perp] = \ell^{v_\ell(n^2)}$. The orthogonal commutes with $\otimes\mathbb{Z}_\ell$ (it is a kernel, and $\mathbb{Z}_\ell$ is flat over $\mathbb{Z}$), and an index of lattices is the product of its ℓ-parts, which gives n^2. In general $[\operatorname{sat}(M) : M] = m_0$ by (iii), so the Gram determinant of $\operatorname{sat}(M)$ is n^2/m_0^2, an integer square, and its ideal of values is $(n/m_0)\mathbb{Z}$; in particular $m_0 \mid n$.

(v) By Lemma 8.69(c), in suitable coordinates $E = \mathbb{C}/\Lambda$, $E' = \mathbb{C}/\Lambda'$, $\psi(z) = z$ with $\Lambda \subseteq \Lambda'$ of index m, and ψ_* on H_1 is this inclusion. Its transpose $\psi^*\colon H^1(E',\mathbb{Z}) \to H^1(E,\mathbb{Z})$ has image of index m (the determinant of a matrix and of its transpose agree). As φ^* is injective on $H^1(E,\mathbb{Z})$ with image $\varphi^* H^1(E,\mathbb{Z})$, the image $\varphi^*\psi^* H^1(E',\mathbb{Z})$ has index m in it. If $\varphi^* H^1(E,\mathbb{Z})$ is saturated and $m > 1$, then $(\varphi')^* H^1(E',\mathbb{Z})$ is a proper sublattice of finite index of a saturated lattice of the same rank, so it is not saturated. □

All the numbers of the proposition can be seen on the least saturated example, $\varphi = [m]\colon E \to E$, $m \geq 2$, of degree $n = m^2$. Here $\varphi^* = m$ on $H^1(E,\mathbb{Z})$, so $M = \varphi^* H^1(E,\mathbb{Z}) = mH^1(E,\mathbb{Z})$, whose saturation is $H^1(E,\mathbb{Z})$, of index m^2. On the other side, $\varphi_* = m$ on $H_1(E,\mathbb{Z}) \simeq \mathbb{Z}^2$ has cokernel $(\mathbb{Z}/m)^2$, of order m^2; the kernel of $[m]$ on $J(E) = E$ is $E[m]$, finite of order m^2 (Proposition 8.71(i)), so it has m^2 components; and $\varphi^* = [m]$ on J has the same kernel. All four quantities of (iii) are m^2, a divisor of $n^{2g_Y} = m^4$. In (iv), the Gram matrix on $M = mH^1$ is m^2 times the unimodular one, so the ideal of values is $m^2\mathbb{Z} = n\mathbb{Z}$ and the determinant $m^4 = n^2$; here $m_0 = m^2$ and the ideal of values on $\operatorname{sat}(M) = H^1(E,\mathbb{Z})$ is $(n/m_0)\mathbb{Z} = \mathbb{Z}$. At the other extreme, a parametrisation of degree one ($X_0(11) \to$ `11a1`) is an isomorphism and every index is 1.

Proposition 8.71 (torsion of Jacobians)**.**

(i) For a complex torus V/Λ of dimension g and $n \geq 1$, $(V/\Lambda)[n] = \frac{1}{n}\Lambda/\Lambda \simeq \Lambda/n\Lambda \simeq (\mathbb{Z}/n)^{2g}$, the middle map being $x \mapsto nx$. Hence $J(X)[n] \simeq H_1(X,\mathbb{Z}/n)$ for a compact Riemann surface X, and $[n]\colon J(X) \to J(X)$ has n^{2g} points in each fibre.

(ii) For a curve C over k with $\operatorname{char} k \nmid n$, $J[n](\bar{k}) \simeq (\mathbb{Z}/n)^{2g}$ as groups, with a continuous action of G_k (stated).

(iii) For a commutative ring $\mathbb{T}$ of endomorphisms of J and an ideal $\mathfrak{a} \subseteq \mathbb{T}$, put $J[\mathfrak{a}] = \{P : tP = 0 \text{ for all } t \in \mathfrak{a}\}$. Then $J[\ell]$ is a $\mathbb{T}/\ell\mathbb{T}$-module, and for a maximal ideal $\mathfrak{m} \ni \ell$, $J[\mathfrak{m}]$ is a vector space over the field $\mathbb{T}/\mathfrak{m}$.

Proof. (i) $x \in V$ maps to an n-torsion point iff $nx \in \Lambda$. Multiplication by n maps $\frac{1}{n}\Lambda$ isomorphically onto Λ and Λ onto $n\Lambda$, so $\frac{1}{n}\Lambda/\Lambda \simeq \Lambda/n\Lambda$; and $\Lambda \simeq \mathbb{Z}^{2g}$. With Theorem 8.66 and $\Lambda_X \simeq H_1(X,\mathbb{Z})$ this gives the second statement; $[n]$ is a surjective homomorphism, so each fibre is a coset of $J[n]$. (ii) is [129, Section 8] (not verified); we do not prove it. (iii) $\mathbb{T}$ acts on $J[\mathfrak{a}]$ because $\mathbb{T}$ is commutative; $\ell\mathbb{T}$ kills $J[\ell]$ and $\mathfrak{m}$ kills $J[\mathfrak{m}]$. □

Definition 8.72 (Tate modules)**.** For a prime ℓ, $T_\ell J = \varprojlim_m J[\ell^m]$, with transition maps multiplication by ℓ, and $V_\ell J = T_\ell J \otimes \mathbb{Q}_\ell$ (Chapter 1 for inverse limits and $\mathbb{Z}_\ell$).

Proposition 8.73 (the Tate module and H^1)**.** *Let X be a compact Riemann surface of genus g and $J = J(X)$.*

(i) The isomorphisms $J[\ell^m] = \ell^{-m}\Lambda_X/\Lambda_X \to \Lambda_X/\ell^m\Lambda_X$, $x \mapsto \ell^m x$, are compatible with the transition maps (multiplication by ℓ on the left, reduction on the right) and give a canonical isomorphism $T_\ell J \simeq \Lambda_X \otimes \mathbb{Z}_\ell = H_1(X,\mathbb{Z}_\ell)$; $T_\ell J$ is free of rank $2g$ and $T_\ell J/\ell^m T_\ell J = J[\ell^m]$.

(ii) (Duality.) $H^1(X,\mathbb{Z}_\ell) = \mathrm{Hom}(H_1(X,\mathbb{Z}),\mathbb{Z}_\ell) \simeq \mathrm{Hom}_{\mathbb{Z}_\ell}(T_\ell J,\mathbb{Z}_\ell)$ canonically: H^1 is the $\mathbb{Z}_\ell$-dual of the Tate module.

(iii) Composing with Poincare duality, $H^1(X,\mathbb{Z}_\ell) \simeq H_1(X,\mathbb{Z}_\ell) \simeq T_\ell J$ is an isomorphism of $\mathbb{Z}_\ell$-modules. It depends on the orientation, it is not Galois-equivariant when X comes from a curve over a number field (Warning 8.75), and it carries the action $\mathcal{C}^*$ of a correspondence on H^1 to the action $(\mathcal{C}^t)_*$ of the transpose on $T_\ell J$ (Theorem 8.81(c)).

(iv) For a curve C over k and $\ell \neq \mathrm{char}\, k$, $T_\ell J$ is free of rank $2g$ over $\mathbb{Z}_\ell$ with a continuous action of G_k (stated). For $g = 1$, $T_\ell J(E) = T_\ell E$ (Chapter 9).

Proof. (i) If $x \in \ell^{-m-1}\Lambda_X$, then $\ell x \in \ell^{-m}\Lambda_X$ is sent to $\ell^m(\ell x) = \ell^{m+1}x$, the image of the class of $\ell^{m+1}x$ under reduction modulo ℓ^m: the squares commute. So $T_\ell J \simeq \varprojlim \Lambda_X/\ell^m\Lambda_X = \Lambda_X \otimes \mathbb{Z}_\ell$ (for a free module of finite rank, $\varprojlim_m \mathbb{Z}^{2g}/\ell^m = \mathbb{Z}_\ell^{2g}$), and $\Lambda_X \simeq H_1(X,\mathbb{Z})$ by Theorem 8.66(iii). (ii) $\mathrm{Hom}(H_1(X,\mathbb{Z}),\mathbb{Z}_\ell) = \mathrm{Hom}_{\mathbb{Z}_\ell}(\varprojlim_m H_1(X,\mathbb{Z}) \otimes \mathbb{Z}_\ell, \mathbb{Z}_\ell)$. (iii) is Theorem 8.60 tensored with $\mathbb{Z}_\ell$, and the last clause is proved in Theorem 8.81(c). (iv) is [129, Section 15] and [138, Section 18] (not verified); we do not prove it. □

Theorem 8.74 (the Weil pairing and etale cohomology; stated)**.** *Let C be a smooth projective curve of genus g over k, J its Jacobian and $\ell \neq \mathrm{char}\, k$.*

(a) (Weil pairing.) There is a perfect, alternating, G_k-equivariant $\mathbb{Z}_\ell$-bilinear pairing $e_\ell\colon T_\ell J \times T_\ell J \to \mathbb{Z}_\ell(1)$ (from the canonical principal polarisation). Over $\mathbb{C}$, after identifying $\mathbb{Z}_\ell(1)$ with $\mathbb{Z}_\ell$ by $\zeta_{\ell^m} = e^{2\pi i/\ell^m}$, it is the intersection pairing on $H_1(X,\mathbb{Z}_\ell)$ up to a universal sign. For $g = 1$ it is the Weil pairing of Chapter 9, and $\det \rho_{E,\ell} = \chi_\ell$.

(b) (Etale cohomology.) $H^1_{\mathrm{et}}(C_{\bar{k}},\mathbb{Z}_\ell)$ is free of rank $2g$ with a continuous action of G_k, and $H^1_{\mathrm{et}}(C_{\bar{k}},\mathbb{Z}_\ell) \simeq \mathrm{Hom}_{\mathbb{Z}_\ell}(T_\ell J,\mathbb{Z}_\ell)$ as G_k-modules (contragredient action, Chapter 4). For $k \subseteq \mathbb{C}$ there is a comparison isomorphism $H^1_{\mathrm{et}}(C_{\bar{k}},\mathbb{Z}_\ell) \simeq H^1(C(\mathbb{C}),\mathbb{Z}) \otimes \mathbb{Z}_\ell$, compatible with Proposition 8.73(ii), with cup products, and with pullbacks and pushforwards along morphisms.

(c) Hence $H^1_{\mathrm{et}}(C_{\bar{k}},\mathbb{Z}_\ell) \simeq T_\ell J(-1) = T_\ell J \otimes \mathbb{Z}_\ell(-1)$ as G_k-modules, and the cup product $H^1 \times H^1 \to H^2_{\mathrm{et}} = \mathbb{Z}_\ell(-1)$ is perfect, alternating and G_k-equivariant. For $g = 1$: $H^1(E,\mathbb{Z}_\ell) \simeq (T_\ell E)^\vee \simeq T_\ell E(-1)$, with determinant χ_ℓ^{-1}.

(d) (Weil.) For $k = \mathbb{F}_q$: the arithmetic Frobenius acts on $T_\ell J$ as the Frobenius endomorphism π_q of J; $P(T) = \det(T - \pi_q \mid T_\ell J)$ has integer coefficients independent of ℓ, degree $2g$ and roots α_i with $|\alpha_i| = \sqrt{q}$; $\#C(\mathbb{F}_{q^m}) = q^m + 1 - \sum_i \alpha_i^m$; and on $H^1 = (T_\ell J)^\vee$ the geometric Frobenius has the same eigenvalues α_i. For $g = 1$, $a_q = q + 1 - \#E(\mathbb{F}_q) = \operatorname{tr}(\mathrm{Frob}_q \mid T_\ell E) = \operatorname{tr}(\mathrm{Frob}_q^{-1} \mid H^1(E))$.

We do not prove this; see [129, Sections 16 and 19] and [130] for (a), (d); [138, Section 20] for the Weil pairing; [132] for (b) and the comparison theorem (all section numbers not verified); and [185, Chapter III, Section 8, and Chapter V, Section 2] for $g = 1$. Part (c) follows from (a) and (b): the Weil pairing gives $T_\ell J \simeq \operatorname{Hom}(T_\ell J, \mathbb{Z}_\ell(1)) = (T_\ell J)^\vee(1)$, so $(T_\ell J)^\vee \simeq T_\ell J(-1)$. In (d), under the contragredient action Frob_q acts on $(T_\ell J)^\vee$ with eigenvalues α_i^{-1}, so the geometric Frobenius Frob_q^{-1} acts with eigenvalues α_i (Appendix B, B-C3).

Warning 8.75 ($H^1 \simeq T_\ell J$ is not Galois-equivariant). The isomorphism $H^1(X, \mathbb{Z}_\ell) \simeq T_\ell J$ of Proposition 8.73(iii) uses Poincare duality, which over a number field is the Weil pairing and carries a Tate twist: the Galois-equivariant statement is $H^1_{\text{ét}} \simeq T_\ell J(-1)$ (Theorem 8.74(c)). For an elliptic curve, $T_\ell E$ has determinant χ_ℓ and $H^1(E, \mathbb{Z}_\ell)$ has determinant χ_ℓ^{-1}; they are not isomorphic as Galois modules. They have the same adjoint: $\mathrm{ad}^0(T^\vee) \simeq \mathrm{ad}^0 T = \mathrm{ad}^0(T(-1))$ (Chapter 4, Appendix B, B-C12(b)). Moreover H^1 carries the action $\mathcal{C}^*$ of correspondences and $T_\ell J$ the action $\mathcal{C}_*$, and Poincare duality turns $\mathcal{C}^*$ into $(\mathcal{C}^t)_*$, not $\mathcal{C}_*$.

In the paper 8.76. Proposition prop:pullback of the paper is Proposition 8.70 applied to $\varphi = \varphi_E \colon X_0(N) \to E$, with two inputs from Chapter 14. Step by step:

(a) "By optimality the kernel B of the map $J_0(N) \to E$ induced by φ is connected; the exact sequence $H_1(J_0(N), \mathbb{Z}) \to H_1(E, \mathbb{Z}) \to \pi_0(B) = 0$ shows that $\varphi_* \colon H_1(X_0(N), \mathbb{Z}) = H_1(J_0(N), \mathbb{Z}) \to H_1(E, \mathbb{Z})$ is surjective, so its dual $\varphi^* \colon H^1(E, \mathbb{Z}) \to H^1(X_0(N), \mathbb{Z})$ is injective with torsion-free cokernel": Proposition 8.70(iii), (c)⇒(b)⇒(a), with Lemma 8.69(a) for the exact sequence and Proposition 8.68(iv) for the factorisation; "the same holds after tensoring with $\mathbb{Z}_\ell$" because a saturated sublattice is a direct summand.

(b) "$\varphi^* H^1(E, \mathbb{C})$, which is spanned by $\varphi^*\omega_E$ and its conjugate, is $\mathbb{C} f\,dz \oplus \mathbb{C}\overline{f\,dz}$": Proposition 8.59(iii) for E, and $\varphi_E^*\omega_E = c_E \cdot 2\pi i f(z)\,dz$ (Chapter 14). "It is defined over $\mathbb{Q}$: $H^1(X_0(N), \mathbb{Q})[I_f]$ is a two-dimensional $\mathbb{Q}$-form of it, and by flatness $H^1(X_0(N), \mathbb{Z}_\ell)[I_f] = H^1(X_0(N), \mathbb{Z})[I_f] \otimes \mathbb{Z}_\ell$ is a saturated lattice of rank two in $H^1(X_0(N), \mathbb{Q}_\ell)[I_f]$. The image of φ^* is a saturated lattice of rank two in the same $\mathbb{Q}_\ell$-plane; so the two coincide": the Hecke operators act on $H^1(X_0(N), \mathbb{Z})$, so kernels commute with the field extension $\mathbb{Q} \to \mathbb{C}$ and with the flat extension $\mathbb{Z} \to \mathbb{Z}_\ell$; and two saturated sublattices with the same rational span are equal.

(c) "φ^* multiplies the fundamental class of H^2 by $\deg \varphi_E$; so $\langle \varphi^* a, \varphi^* b \rangle_{X_0(N)} = \deg \varphi_E \, \langle a, b \rangle_E$": Proposition 8.62(iv).

(d) "w_N preserves the plane, on which it acts by $\varepsilon_N(f)$": the plane is also the eigenspace of the anemic Hecke algebra for the eigenvalues of f (strong multiplicity one for the newform f, Chapter 13), which w_N preserves; then $w_N^*(f\,dz) = (f|_2 W_N)\,dz = \varepsilon_N(f) f\,dz$ (Chapter 12), and likewise on the conjugate since $\varepsilon_N(f) = \pm 1$ is real. Hence $\langle \varphi^* a, w_N^* \varphi^* b \rangle = \varepsilon_N(f) \deg \varphi_E \langle a, b \rangle_E$.

(e) "the Gram determinant of a rank-two alternating form is the square of its ideal of values": Chapter 3; this is Proposition 8.70(iv).

Proposition 8.70(iv), (v) also explain "minimal degree" in the definition of the optimal curve: for a non-optimal parametrisation the image of φ^* is not saturated, and the ideal of values on its saturation is $(n/m_0)\mathbb{Z}$, with m_0 the order of the component group of Proposition 8.70(iv). Writing $\varphi = \psi \circ \varphi_{\mathrm{opt}}$ with ψ an isogeny, the kernel of $\varphi_{\mathrm{opt},*}$ is connected, so $m_0 = \#\ker\psi = \deg\psi$ and $n/m_0 = \deg\varphi_{\mathrm{opt}}$ is the degree of the optimal parametrisation through which φ factors (Chapter 14). Over $\mathbb{Z}_\ell$ only the ℓ-part of m_0 matters, which is why, when $E[\ell]$ is irreducible, the choice of curve in the class does not change v_ℓ (Section 1 of the paper).

In the paper 8.77. The paragraph after Proposition prop:pullback: "The lattice $M_{f,\lambda}$ of [49] is therefore $H^1(E,\mathbb{Z}_\ell) = \mathrm{Hom}(T_\ell E,\mathbb{Z}_\ell) \simeq T_\ell E(-1)$, by Galois-equivariance of φ^* in étale cohomology, and its adjoint is $\mathrm{ad}^0\, T_\ell E$". This is Proposition 8.73(ii) and Theorem 8.74(b), (c): the comparison isomorphism is compatible with φ_E^*, and φ_E is defined over $\mathbb{Q}$. Remark rem:free: "$J_0(N)[\mathfrak{m}]$ is two-dimensional" is a statement about the $\mathbb{T}/\mathfrak{m}$-vector space of Proposition 8.71(iii); "the Tate module is free of rank two" concerns $T_\ell J_0(N)_{\mathfrak{m}}$ with the action t_*; and "The identification of $T_\ell J_0(N)$ with $H^1(X_0(N),\mathbb{Z}_\ell)$ as Hecke modules uses Poincaré duality composed with w_N, which is not Galois equivariant" is Proposition 8.73(iii) and Warning 8.75: PD turns t^* into $(t^t)_* = (w_N t w_N)_*$ (Theorem 8.81(c) and Chapter 14), so $x \mapsto w_{N*}\,\mathrm{PD}(x)$ is Hecke-equivariant.

8.12 Correspondences, their actions, and adjoints

Hecke operators are correspondences: for $p \nmid N$, T_p on $X_0(N)$ is the pair of maps $X_0(Np) \rightrightarrows X_0(N)$ given by $z \mapsto z$ and $z \mapsto pz$ (Chapter 14). This section defines correspondences between curves, their actions on divisors, the Jacobian, H_1, H^1 and holomorphic differentials, and proves the general theorem behind the sentence of Section 4.1 of the paper "the Hecke operators, U_p included, are self-adjoint for it, because $w_{M^\Sigma} T_n w_{M^\Sigma}^{-1}$ is the adjoint of T_n for the cup product": the adjoint of a correspondence for the cup product is its transpose (Theorem 8.81). Corollary 8.82 then turns "the transpose of every t is wtw" into "every t is self-adjoint for the perfect alternating pairing $\langle x, w^*y\rangle$", and gives the orthogonal splitting into local components used in Lemma lem:hecke and in Step 2 of the proof of Theorem thm:quant. The specific identity $T_n^t = w_N T_n w_N$ on $X_0(N)$ is proved in Chapter 14.

Definition 8.78 (correspondences)**.** Let X, Y be smooth projective curves over k (or compact Riemann surfaces). A *correspondence* $\mathcal{C}$ from X to Y is a triple (C,α,β) with C a finite disjoint union of smooth projective curves and $\alpha\colon C \to X$, $\beta\colon C \to Y$ morphisms nonconstant on every component of C. Its *transpose* is $\mathcal{C}^t = (C,\beta,\alpha)$, from Y to X. The *sum* of two correspondences is the disjoint union. For automorphisms u of Y and v of X put $u\mathcal{C}v = (C, v^{-1}\circ\alpha, u\circ\beta)$.

Examples. (a) The *graph* $\Gamma_\varphi = (X,\mathrm{id},\varphi)$ of a nonconstant morphism $\varphi\colon X \to Y$, and its transpose $\Gamma_\varphi^t = (X,\varphi,\mathrm{id})$. (b) An automorphism w of X gives Γ_w, whose transpose acts as $\Gamma_{w^{-1}}$ (Proposition 8.80(c) and Proposition 8.62(v)). (c) (Forward pointer, Chapter 14.) For a prime $p \nmid N$, the Hecke correspondence $T_p = (X_0(Np),\alpha_1,\alpha_p)$ on $X_0(N)$, with $\alpha_1(z) = z$ and $\alpha_p(z) = pz$ on $\mathcal{H}$. For $p \mid N$ the same triple is $U_p^t = w_N U_p w_N$, not U_p, and U_p is $(X_0(Np),\alpha_p,\alpha_1)$ (Chapter 14). The image of $(\alpha,\beta)\colon C \to X\times Y$ is a divisor on the surface $X\times Y$, and correspondences up to the obvious equivalence form a ring under composition (fibre products); we need neither, because the Hecke algebra is defined as the ring of operators that the correspondences generate (Chapter 13).

Definition 8.79 (actions of a correspondence)**.** Let $\mathcal{C} = (C,\alpha,\beta)$ be a correspondence from X to Y (over $\mathbb{C}$ for (ii) to (iv)).

(i) On divisors and the Jacobian: $\mathcal{C}_* = \beta_*\alpha^*\colon \operatorname{Div}(X) \to \operatorname{Div}(Y)$; it multiplies degrees by $\deg\alpha$ and maps principal divisors to principal divisors (Corollary 8.39(iii)), so it induces $\mathcal{C}_*\colon J(X) \to J(Y)$.

(ii) On homology: $\mathcal{C}_* = \beta_*\alpha^!\colon H_1(X,\mathbb{Z}) \to H_1(Y,\mathbb{Z})$, with the transfer $\alpha^!$ of Proposition 8.62(ii).

(iii) On cohomology: $\mathcal{C}^* = \alpha_*\beta^*\colon H^1(Y,\mathbb{Z}) \to H^1(X,\mathbb{Z})$, with α_* the pushforward of Proposition 8.62(iii).

(iv) On holomorphic differentials: $\mathcal{C}^*\omega = \operatorname{Tr}_\alpha(\beta^*\omega)$, the trace along α of Proposition 8.68(iii), which is holomorphic.

The same definitions apply with coefficients in $\mathbb{Z}_\ell$, $\mathbb{Q}_\ell$ or $\mathbb{C}$, and componentwise when C is disconnected.

Proposition 8.80 (compatibilities)**.** *Let $\mathcal{C} = (C,\alpha,\beta)$ be a correspondence from X to Y.*

(a) $(\mathcal{C}^*\xi)(\gamma) = \xi(\mathcal{C}_*\gamma)$ for $\xi \in H^1(Y,\mathbb{Z})$ and $\gamma \in H_1(X,\mathbb{Z})$: $\mathcal{C}^*$ on H^1 is the transpose of $\mathcal{C}_*$ on H_1.

(b) Under Abel-Jacobi, $\mathcal{C}_*$ on $J(X)$ is induced by the transpose of $\mathcal{C}^*$ on holomorphic differentials and, on lattices, by $\mathcal{C}_*$ on H_1. Hence on $T_\ell J(X) \simeq H_1(X,\mathbb{Z}_\ell)$ a correspondence acts by $\mathcal{C}_*$, and on $H^1(X,\mathbb{Z}_\ell) = \operatorname{Hom}(T_\ell J(X),\mathbb{Z}_\ell)$ by the transpose.

(c) For a graph: $\Gamma_\varphi^* = \varphi^*$ on H^1 and on differentials; $(\Gamma_\varphi)_* = \varphi_*$ on H_1 and on J (Albanese); $(\Gamma_\varphi^t)_* = \varphi^!$ on H_1 and φ^* on J (Picard); $(\Gamma_\varphi^t)^* = \varphi_*$ on H^1.

(d) The actions are additive in $\mathcal{C}$, and $u\mathcal{C}v$ acts by $u_*\mathcal{C}_*v_*$ on H_1 and by $v^*\mathcal{C}^*u^*$ on H^1; moreover $(u\mathcal{C}v)^t = v^{-1}\mathcal{C}^t u^{-1}$.

Proof. (a) $(\alpha_*\beta^*\xi)(\gamma) = (\beta^*\xi)(\alpha^!\gamma) = \xi(\beta_*\alpha^!\gamma)$, by the definitions of α_* on H^1 as the transpose of $\alpha^!$ and of β^* as the transpose of β_*. (b) (Sketch.) Compose Proposition 8.68(iii) for α (pullback along α: transpose of the trace, transfer on lattices) with (ii) for β (pushforward: transpose of β^*, β_* on lattices). The statement on $T_\ell J$ follows from Proposition 8.73(i), which is natural for homomorphisms of tori, and the one on H^1 from (a). (c) Substitute $\alpha = \mathrm{id}$, $\beta = \varphi$, respectively $\alpha = \varphi$, $\beta = \mathrm{id}$; on J, $(\Gamma_\varphi^t)_*D = \mathrm{id}_*\varphi^*D = \varphi^*D$. (d) Additivity is clear. By Proposition 8.62(v), $(u\beta)_*(v^{-1}\alpha)^! = u_*\beta_*\alpha^!(v^{-1})^! = u_*\beta_*\alpha^!v_*$, and $(v^{-1}\alpha)_*(u\beta)^* = (v^{-1})_*\alpha_*\beta^*u^* = v^*\alpha_*\beta^*u^*$ on H^1. The transpose of $(C, v^{-1}\alpha, u\beta)$ is $(C, u\beta, v^{-1}\alpha) = v^{-1}(C,\beta,\alpha)u^{-1}$ in the notation of Definition 8.78. □

Theorem 8.81 (the adjoint of a correspondence is its transpose)**.** *Let $\mathcal{C} = (C,\alpha,\beta)$ be a correspondence from X to Y (compact Riemann surfaces). For all $\xi \in H^1(Y,\mathbb{Z})$ and $\eta \in H^1(X,\mathbb{Z})$,*

$$\langle \mathcal{C}^*\xi, \eta\rangle_X = \langle \xi, (\mathcal{C}^t)^*\eta\rangle_Y,$$

that is, for the cup products, $(\mathcal{C}^*)^\dagger = (\mathcal{C}^t)^*$. Consequently:

(a) for an automorphism w of X, $\langle w^*x, w^*y\rangle = \langle x, y\rangle$: w^* is an isometry, with adjoint $(w^{-1})^*$;

(b) for a nonconstant $\varphi\colon X \to Y$, $\langle \varphi^*\xi, \eta\rangle_X = \langle \xi, \varphi_*\eta\rangle_Y$, and Proposition 8.70(i), (ii) follow again;

(c) $\mathrm{PD}_X \circ \mathcal{C}^* = (\mathcal{C}^t)_* \circ \mathrm{PD}_Y$: *under Poincare duality the action* $\mathcal{C}^*$ *on* H^1 *corresponds to the action of the transpose on* H_1*, hence on* $T_\ell J$*;*

(d) *the same holds with coefficients in* $\mathbb{Z}_\ell$*,* $\mathbb{Q}_\ell$ *or* $\mathbb{C}$*, and for* $\mathbb{Z}_\ell$*-linear combinations of correspondences.*

Proof. The projection formula (Proposition 8.62(iv)) and alternation give, for a nonconstant $\varphi\colon X_1 \to Y_1$, $\theta \in H^1(X_1)$, $\zeta \in H^1(Y_1)$, both

$$\langle \varphi_*\theta, \zeta\rangle_{Y_1} = \langle \theta, \varphi^*\zeta\rangle_{X_1} \quad \text{and} \quad \langle \zeta, \varphi_*\theta\rangle_{Y_1} = -\langle \varphi_*\theta, \zeta\rangle_{Y_1} = -\langle \theta, \varphi^*\zeta\rangle_{X_1} = \langle \varphi^*\zeta, \theta\rangle_{X_1}.$$

Apply the first to $\varphi = \alpha$ (componentwise on C) and the second to $\varphi = \beta$:

$$\langle \alpha_*\beta^*\xi, \eta\rangle_X = \langle \beta^*\xi, \alpha^*\eta\rangle_C = \langle \xi, \beta_*\alpha^*\eta\rangle_Y.$$

The identity holds on integral classes, hence with any coefficients by linearity. (a) Take $\mathcal{C} = \Gamma_w$: $\Gamma_w^* = w^*$ and $(\Gamma_w^t)^* = w_* = (w^{-1})^*$ (Proposition 8.62(v)); so $\langle w^*x, w^*y\rangle = \langle x, (w^{-1})^*w^*y\rangle = \langle x, y\rangle$. (b) Take $\mathcal{C} = \Gamma_\varphi$. (c) For $\eta \in H^1(X, \mathbb{Z})$: $\eta(\mathrm{PD}_X\, \mathcal{C}^*\xi) = \langle \mathcal{C}^*\xi, \eta\rangle_X = \langle \xi, (\mathcal{C}^t)^*\eta\rangle_Y = ((\mathcal{C}^t)^*\eta)(\mathrm{PD}_Y\, \xi) = \eta((\mathcal{C}^t)_*\, \mathrm{PD}_Y\, \xi)$, by Proposition 8.80(a) for $\mathcal{C}^t$. With Proposition 8.73(i) and Proposition 8.80(b) this is the statement on $T_\ell J$. (d) is linearity. □

Corollary 8.82 (twisted pairings and self-adjoint Hecke algebras)**.** *Let* X *be a compact Riemann surface,* w *an automorphism of* X *with* $w^2 = \mathrm{id}$*, and* $\mathbb{T}$ *a commutative* $\mathbb{Z}_\ell$*-subalgebra of* $\mathrm{End}_{\mathbb{Z}_\ell}(H^1(X, \mathbb{Z}_\ell))$ *(so a* $\mathbb{Z}_\ell$*-submodule, not merely a subring), each of whose elements is of the form* $t = \sum_i c_i\mathcal{C}_i^*$ *with* $c_i \in \mathbb{Z}_\ell$ *and* $\mathcal{C}_i$ *correspondences from* X *to* X*. Put* $t^t = \sum_i c_i(\mathcal{C}_i^t)^*$ *(well defined, being the adjoint* $t^\dagger$ *by Theorem 8.81), and assume* $t^t = w^*tw^*$ *for all* $t \in \mathbb{T}$*. Put* $[x, y] = \langle x, w^*y\rangle$*. Then:*

(i) $[\ ,\ ]$ *is a perfect alternating pairing on* $H^1(X, \mathbb{Z}_\ell)$*;*

(ii) *every* $t \in \mathbb{T}$ *is self-adjoint for* $[\ ,\ ]$*:* $[tx, y] = [x, ty]$*;*

(iii) *every idempotent* e *of* $\mathbb{T}$ *is self-adjoint,* $H^1(X, \mathbb{Z}_\ell) = eH^1 \oplus (1 - e)H^1$ *is an orthogonal decomposition and* $[\ ,\ ]$ *is perfect on each summand; in particular,* $\mathbb{T}$ *being a finite* $\mathbb{Z}_\ell$*-algebra,* $H^1(X, \mathbb{Z}_\ell) = \bigoplus_{\mathfrak{m}} H^1(X, \mathbb{Z}_\ell)_{\mathfrak{m}}$ *over the maximal ideals of* $\mathbb{T}$ *is orthogonal for* $[\ ,\ ]$*, with* $[\ ,\ ]$ *perfect on each* $H^1(X, \mathbb{Z}_\ell)_{\mathfrak{m}}$*.*

Proof. By Theorem 8.81, $t^\dagger = t^t = w^*t(w^*)^{-1}$ for the cup product, which is perfect and antisymmetric on $H^1(X, \mathbb{Z}_\ell)$ (Theorem 8.60). By Theorem 8.81(a), w^* is an isometry, and w^* is an involution, so $(w^*)^\dagger = (w^*)^{-1} = w^*$. The proposition on adjoints and twisted pairings of Chapter 3 (its parts on adjoints, idempotents and twisted pairings) now gives: $[\ ,\ ]$ is perfect, as the composite of a perfect pairing with the automorphism w^*; for $t \in \mathbb{T}$, $[tx, y] = \langle x, t^\dagger w^*y\rangle = \langle x, w^*tw^*w^*y\rangle = [x, ty]$; and $[y, x] = \langle y, w^*x\rangle = -\langle w^*x, y\rangle = -\langle x, w^*y\rangle = -[x, y]$, so $[\ ,\ ]$ is antisymmetric, hence alternating since 2 is a nonzerodivisor in $\mathbb{Z}_\ell$. For (iii), the same proposition of Chapter 3 shows that idempotents of a commutative ring of self-adjoint endomorphisms are self-adjoint, that the decomposition is orthogonal and that the pairing is perfect on each summand. $\mathbb{T}$ is a $\mathbb{Z}_\ell$-submodule of the finite free module $\mathrm{End}_{\mathbb{Z}_\ell}(H^1(X, \mathbb{Z}_\ell))$ by hypothesis, so it is finite and free over $\mathbb{Z}_\ell$ (a submodule of a finite free module over the principal ideal domain $\mathbb{Z}_\ell$), and it is the product of its localisations $\mathbb{T}_{\mathfrak{m}}$, cut out by idempotents $e_{\mathfrak{m}}$ (Chapter 3); $H^1(X, \mathbb{Z}_\ell)_{\mathfrak{m}} = e_{\mathfrak{m}}H^1(X, \mathbb{Z}_\ell)$. □

Example 8.83 (adjoints of correspondences)**.**

(a) On $X=\mathbb{C}/\Lambda$ the automorphism $[-1]$ acts by -1 on H^1; it is an isometry and its own adjoint (Example 8.61).

(b) For $\varphi\colon X\to E$ of degree n, the correspondence Γ_φ^t followed by Γ_φ acts on $H^1(E)$ by $\varphi_*\varphi^*=n$ and on $E=J(E)$ by $[n]$ (Proposition 8.70(ii)). On $H^1(X,\mathbb{Q})$ the operator $p=\frac{1}{n}\varphi^*\varphi_*$ satisfies $p^2=\frac{1}{n^2}\varphi^*(\varphi_*\varphi^*)\varphi_*=p$, has image $\varphi^*H^1(E,\mathbb{Q})$ and is the identity there; and $p^\dagger=\frac{1}{n}\varphi_*^\dagger\varphi^{*\dagger}=\frac{1}{n}\varphi^*\varphi_*=p$ by Theorem 8.81(b) (for an antisymmetric pairing $(A^\dagger)^\dagger=A$). So p is the orthogonal projector onto $\varphi^*H^1(E,\mathbb{Q})$ for the cup product; it is integral on $H^1(X,\mathbb{Z}_\ell)$ for $\ell\nmid n$.

(c) On a genus-one curve E, for an endomorphism ψ (a nonconstant morphism fixing O) the adjoint of ψ^* on $H^1(E,\mathbb{Z})$ is $\psi_*=(\deg\psi)(\psi^*)^{-1}$ (on $H^1(E,\mathbb{Q})$; by Theorem 8.81(b) and Proposition 8.70(ii), $\psi_*\psi^*=\deg\psi$). For $\psi=[m]$, $\psi^*=\psi_*=m$ is self-adjoint. For $E=\mathbb{C}/\mathbb{Z}[i]$ and $\psi(z)=iz$: with $z=s+it$, $\psi^*s=-t$ and $\psi^*t=s$, so in the basis ds, dt the matrix of ψ^* is $\left(\begin{smallmatrix}0&1\\-1&0\end{smallmatrix}\right)$ (which is the matrix J of Chapter 1), a rotation of order 4; its adjoint for the Gram matrix $G=\left(\begin{smallmatrix}0&1\\-1&0\end{smallmatrix}\right)$ is $G^{-1}(\psi^*)^{\mathsf T}G=\left(\begin{smallmatrix}0&-1\\1&0\end{smallmatrix}\right)=(\psi^*)^{-1}$, the inverse rotation. So a correspondence need not be self-adjoint for the cup product.

(d) (Forward pointer, Chapter 14.) On $X_0(N)$, $T_n^t=w_NT_nw_N$ for all n, U_p included. For $p\nmid N$, w_N commutes with T_p, so T_p^t acts as T_p and T_p^* is self-adjoint for the cup product; for $p\mid N$, $U_p^t=w_NU_pw_N$ is in general not U_p, and U_p^* is not self-adjoint for the cup product. This is why the paper composes the cup product with w: by Corollary 8.82 every t is self-adjoint for $\langle x,w_N^*y\rangle$.

In the paper 8.84. In Section 4.1 of the paper, the pairing $\hat\delta_!$ "is perfect and alternating on $H^1(X_0(M^\Sigma),\mathbb{Z}_\ell)$, and the Hecke operators, U_p included, are self-adjoint for it, because $w_{M^\Sigma}T_nw_{M^\Sigma}^{-1}$ is the adjoint of T_n for the cup product", which is what the composition with w is for. With the input $T_n^t=w_{M^\Sigma}T_nw_{M^\Sigma}$ from Chapter 14, Theorem 8.81 says that $w^*T_n^*w^*$ is the adjoint of T_n^*, and Corollary 8.82(i), (ii) is the sentence, with $X=X_0(M^\Sigma)$, $w=w_{M^\Sigma}$ and $\mathbb{T}$ the image of the Hecke algebra tensored with $\mathbb{Z}_\ell$ in $\mathrm{End}_{\mathbb{Z}_\ell}(H^1(X_0(M^\Sigma),\mathbb{Z}_\ell))$, a commutative $\mathbb{Z}_\ell$-subalgebra. Every element of $\mathbb{T}$ is a $\mathbb{Z}_\ell$-combination of the T_n^* ($\mathbb{T}$ is the $\mathbb{Z}$-span of the T_n, by the multiplicativity relations of Chapter 13), so the identity $t^t=w^*tw^*$ follows from the case $t=T_n$ by linearity; the factor $\frac12$ in $\hat\delta_!$ is a unit. The paragraph after Lemma lem:hecke and Step 2 of the proof of Theorem thm:quant: "the idempotent $e_\mathfrak{m}$ is self-adjoint for $\hat\delta_!$, so $H^1(X_0(N),\mathbb{Z}_\ell)$ splits orthogonally into its local components and the pairing is perfect on each" is Corollary 8.82(iii). This supplies the hypothesis of Lemma lem:ddt417 for the module $L=H^1(X_0(N),\mathbb{Z}_\ell)_\mathfrak{m}$: a perfect $\mathbb{Z}_\ell$-bilinear pairing for which $\mathbb{T}_\mathfrak{m}$ is self-adjoint.

8.13 Exercises

Exercise 8.85. (a) Show that $y^2=x^3+ax+b$ ($\mathrm{char}\,k\neq2,3$) is singular iff $4a^3+27b^2=0$, and that the singular point is then $(x_0,0)$ with x_0 the double root. (b) For the cusp $y^2=x^3$ show that $t\mapsto(t^2,t^3)$ is a bijection $\mathbb{A}^1\to C$ which is not an isomorphism, by computing $\dim\mathfrak{m}_P/\mathfrak{m}_P^2$ at $P=(0,0)$. (c) Show that the Fermat curve $X^d+Y^d+Z^d=0$ is singular at every point when $p=\mathrm{char}\,k$ divides d, and that for $d=2p$ it is not even irreducible. *Hints.* (a) A singular point has $f_y=2y=0$, and then x is a common root of x^3+ax+b and $3x^2+a$; the

discriminant of x^3+ax+b is $-(4a^3+27b^2)$. (b) $f=y^2-x^3$ has no linear term at $(0,0)$. (c) $X^{2p}+Y^{2p}+Z^{2p}=(X^2+Y^2+Z^2)^p$.

Exercise 8.86. For `121a1` ($y^2+xy+y=x^3+x^2-30x-76$) and `20a1` ($y^2=x^3+x^2+4x+4$) show that the three partial derivatives of the homogenised equation have no common zero on the curve over $\overline{\mathbb{Q}}$. For which primes p is the reduction of the model of `20a1` modulo p singular? (Answer: 2 and 5; at 2 find the singular point.) *Hint.* The discriminant of the model of `20a1` is $-2^8\cdot 5^2=-6400$. Modulo 2 the equation is $y^2=x^3+x^2$, with $f_y\equiv 0$ and $f_x\equiv x^2$, singular at $(0,0)$; modulo 5, $x^3+x^2+4x+4\equiv(x+1)^2(x-1)$, singular at $(-1,0)$.

Exercise 8.87. On $\mathbb{P}^1$ show that $l(D)=\deg D+1$ for every divisor of degree ≥ -1, by reducing to $D=n(\infty)$ with Proposition 8.24(i). Deduce Riemann-Roch for $\mathbb{P}^1$ with $g=0$ and $K=-2(\infty)$, including the cases $\deg D\leq -2$. *Hint.* $\mathcal{L}(n(\infty))$ is the space of polynomials in x of degree at most n.

Exercise 8.88. Let h be squarefree of degree 4, $\operatorname{char}k\neq 2$, and C the smooth projective model of $y^2=h(x)$ (Corollary 8.45(c)). Show that C has two points over ∞, that $\operatorname{div}(dx/y)=0$, and that $g(C)=1$. If h has no root in k and its leading coefficient is not a square, C may have no k-rational point at infinity: what does Theorem 8.33 need before it applies?

Exercise 8.89. Let C have genus one, $O\in C(k)$, and x, y as in Theorem 8.33. Show that $\{x^iy^j : j\in\{0,1\},\ 2i+3j\leq n\}$ is a basis of $\mathcal{L}(n(O))$ for every $n\geq 1$. Explain why the construction cannot be started on the conic $X^2+Y^2+Z^2=0$ over $\mathbb{Q}$ or on Selmer's cubic.

Exercise 8.90. On a Weierstrass cubic with $O=[0:1:0]$, use Proposition 8.34 to show: (a) if a line meets E in P, Q, R (with multiplicity), then $\kappa(P)+\kappa(Q)+\kappa(R)=0$; (b) the inverse of $P=(x_0,y_0)$ is $(x_0,-y_0-a_1x_0-a_3)$; (c) P has order 2 iff $2y_0+a_1x_0+a_3=0$.

Exercise 8.91. For a Weierstrass cubic with $\operatorname{char}k\neq 2,3$, show that $x\colon C\to\mathbb{P}^1$ has degree 2 and is ramified exactly at O and at the three points with $2y+a_1x+a_3=0$, and verify Riemann-Hurwitz. Show that $y\colon C\to\mathbb{P}^1$ has degree 3, that $e_y(O)=3$, and that the total ramification $\sum(e_y(P)-1)$ is 6.

Exercise 8.92. (a) Show that the plane quartic $y^3=x^4-1$ (projectively $X^4-Y^3Z-Z^4=0$) is smooth in characteristic 0, and compute its genus twice: by Theorem 8.31, and by Riemann-Hurwitz for $x\colon C\to\mathbb{P}^1$ (degree 3, totally ramified over the four roots of $x^4=1$ and over ∞). (b) For the Fermat quartic, show that ω_0, $x\omega_0$, $y\omega_0$ ($\omega_0=dx/f_y$) are regular, by checking the order at the four points at infinity. *Answer to (a):* $g=3$ both times; Riemann-Hurwitz reads $2g-2=3(-2)+5\cdot(3-1)=4$.

Exercise 8.93. Let $\varphi\colon X\to E$ be a nonconstant morphism over $\mathbb{C}$ from a curve of genus 2 to a curve of genus 1. Show that φ has either two ramification points with $e=2$, or one with $e=3$, and give the possible ramification patterns over the branch points when $\deg\varphi=2$. Show that a nonconstant morphism from a genus-one curve to $\mathbb{P}^1$ has degree at least 2. *Hint.* Riemann-Hurwitz gives $\sum(e_\varphi(P)-1)=2$. If $\deg\varphi=2$, a point with $e=2$ is its whole fibre, so there are exactly two branch points, each with a single preimage. A morphism of degree one is an isomorphism (Corollary 8.39(v)).

Exercise 8.94. The optimal curves `37a1` and `99a1` have modular degrees 2 and 4 (Cremona's tables), and $g(X_0(37))=2$, $g(X_0(99))=9$. Compute the total ramification of their modular

parametrisations. Show that for every optimal E of conductor N, $\deg\varphi_E = 1$ forces $g(X_0(N)) = 1$, and that $g(X_0(N)) \geq 2$ forces $\deg\varphi_E \geq 2$. (Answers: 2 and 16; we checked the genera with `mfdim` and the degrees with `ellmoddegree`.)

Exercise 8.95. For $X = \mathbb{C}/\Lambda$ and a new basis $(\omega_1', \omega_2') = (a\omega_1 + b\omega_2, c\omega_1 + d\omega_2)$ of Λ, $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{Z})$, compute the cup product of the new dual basis ds', dt' and show $\langle ds', dt' \rangle = \det\gamma \cdot \langle ds, dt \rangle$. Deduce that $\mathrm{Im}(\bar{\omega}_1'\omega_2') > 0$ iff $\det\gamma = 1$, and that the convention "$a \cdot b = +1$" of Example 8.61 singles out the bases oriented by the complex structure.

Exercise 8.96. Let T be a free $\mathbb{Z}_\ell$-module of rank two with a continuous action of a group G and a perfect alternating G-equivariant pairing $e\colon T \times T \to \mathbb{Z}_\ell(1)$. Show that $\det T = \chi_\ell$ (as a character of G), that $x \mapsto e(x, -)$ is a G-isomorphism $T \to T^\vee(1)$, and hence $T^\vee \simeq T(-1)$ with $\det T^\vee = \chi_\ell^{-1}$. Apply this to $T = T_\ell E$ and explain why the paper's lattice $M_{f,\lambda} = \varphi_E^* H^1(E, \mathbb{Z}_\ell)$ is isomorphic to the dual of $T_\ell E$, and not to $T_\ell E$, as a Galois module, and why $\mathrm{ad}^0 M_{f,\lambda} \simeq \mathrm{ad}^0 T_\ell E$ anyway.

Exercise 8.97. Let $E = \mathbb{C}/\mathbb{Z}[\zeta_3]$ and $\psi(z) = \zeta_3 z$. Write the matrix of ψ^* on $H^1(E, \mathbb{Z})$ in the basis dual to 1, ζ_3, and of its adjoint for the cup product. Show that ψ^* is an isometry with $(\psi^*)^\dagger = (\psi^*)^2$ and that $\psi^* + (\psi^*)^\dagger = -1$. Which elements of $\mathbb{Z}[\psi^*]$ are self-adjoint? *Hint.* With $z = s + t\zeta_3$ and $\zeta_3^2 = -1 - \zeta_3$, $\psi(z) = -t + (s - t)\zeta_3$, so $\psi^* ds = -dt$ and $\psi^* dt = ds - dt$. Use the formula $G^{-1}P^{\mathsf{T}}G$ of Example 8.83(c). (Answer to the last question: only the integers.)

Exercise 8.98. Let $L = \mathbb{Z}_\ell^2$ with $\langle x, y \rangle = x_1 y_2 - x_2 y_1$, ℓ odd. (a) For $w = \mathrm{diag}(2, \frac{1}{2})$, an isometry of infinite order, show that $[x, y] = \langle x, wy \rangle$ is perfect but not alternating. (b) For $w = \mathrm{diag}(1, -1)$, an involution, show that w is not an isometry and that $[\ ,\ ]$ is symmetric. (c) Conclude that both hypotheses on w in Corollary 8.82 (an isometric involution, which an automorphism of X of order two provides) are needed for alternation.

Exercise 8.99. Let $H = \mathbb{Z}^4$ with basis $a_1^\vee, a_2^\vee, b_1^\vee, b_2^\vee$ and the symplectic cup product of Theorem 8.60, and M the span of $u = a_1^\vee$ and $v = nb_1^\vee + b_2^\vee$. Show that M is saturated, that the pairing on M has ideal of values $n\mathbb{Z}$, compute $M^\perp$ and show $[H : M \oplus M^\perp] = n^2$, as Proposition 8.70(iv) predicts for $M = \varphi^* H^1(E, \mathbb{Z})$ when $g(X) = 2$. Do the same for $M' = \mathbb{Z}u \oplus \mathbb{Z} \cdot 2v$ and compare with the non-saturated case. (Answers: $M^\perp = \mathbb{Z}(a_1^\vee - na_2^\vee) \oplus \mathbb{Z}b_2^\vee$; for M' the ideal of values is $2n\mathbb{Z}$, $M'^\perp = M^\perp$, and the index is $2n^2$.)

Exercise 8.100. Let $V = \mathbb{C}^2$, $\Lambda = \mathbb{Z}[i]^2$, $W = \mathbb{C}$, $M = \mathbb{Z}[i]$ and $A(z_1, z_2) = 2z_1 + (1+i)z_2$. Show that A induces a surjective homomorphism π of complex tori, compute $A(\Lambda)$ and show that $\ker\pi$ has two connected components. Replace A by $z_1 + (1+i)z_2$ and show that the kernel becomes connected. *Hint.* $2 = -i(1+i)^2$, so $A(\Lambda) = (1+i)\mathbb{Z}[i]$, of index 2 in $\mathbb{Z}[i]$; apply Lemma 8.69(a).

Exercise 8.101. Let $E\colon y^2 = x^3 - x$ over $\mathbb{F}_3$. Count $E(\mathbb{F}_3)$, the fixed points of π_3, and deduce a_3 and the roots α, β of $T^2 - a_3 T + 3$. Predict $\#E(\mathbb{F}_9)$ from Theorem 8.74(d) and verify it by counting the fixed points of π_3^2 (answers: 4, $a_3 = 0$, 16). Show that π_3 is a bijection on $E(\bar{\mathbb{F}}_3)$ of degree 3, and explain why Theorem 8.44 does not apply to it.

Exercise 8.102. (a) On $\mathbb{P}^1$ compute all residues of $\omega = dz/(z^3 - z)$, including at ∞, check Theorem 8.52, and deduce the partial fraction decomposition of $1/(z^3 - z)$. (b) Show that on a compact Riemann surface no meromorphic 1-form has a single simple pole and no other pole. (c) On a Weierstrass cubic, show that $x\,dx/(2y + a_1 x + a_3)$ has a double pole at O and no other pole, and deduce that its residue at O is 0. (Answer to (a): the residues are -1 at 0, $\frac{1}{2}$ at ± 1 and 0 at ∞.)

8.14 Notes and references

The algebraic side (Sections 8.1 to 8.7) follows Silverman [185], Chapter I (Sections 1 to 3: varieties, Galois action, maps) and Chapter II (Sections 1 to 5: curves, divisors, differentials, Riemann-Roch), and Chapter III, Section 3 for Weierstrass equations. The numbered results of Silverman cited above (Propositions II.1.1, II.2.1, II.2.6, II.2.11, II.4.2, II.4.3, II.5.8, Theorems II.2.3, II.2.4, II.5.4, Corollary II.2.12) are cited from the second edition as we recall them; the reader should treat the numbers as pointers and check them against the printed edition. Fulton [72] is the gentlest complete account of plane curves, smoothness, intersection multiplicities and Bezout (Chapters 3, 5), the smooth model (Chapter 7) and Riemann-Roch (Chapter 8); Hartshorne [79] (Chapter I, Sections 1 to 7; Chapter II, Section 6; Chapter IV, Sections 1 and 2; Appendix B) gives the scheme-theoretic versions; Corollary I.6.12, Proposition II.6.9, Theorem IV.1.3 and Corollary IV.2.4 are cited as recalled. The finiteness of integral closure is in Atiyah and Macdonald [7], Chapter 5 (chapter not verified).

The analytic side (Sections 8.8 to 8.11) follows Miranda [136] (Riemann surfaces and holomorphic maps in Chapters I and II, differentials and residues in Chapter IV, Riemann-Roch and Riemann existence in Chapters V to VII, Abel's theorem, Jacobi inversion and the bilinear relations in Chapter VIII) and Forster [70] (Sections 1, 2 and 10 for the local theory, 14 to 17 for Riemann-Roch and its consequences, 19 to 21 for de Rham, periods and Abel-Jacobi). Griffiths and Harris [75], Chapter 2, Section 2, and Farkas and Kra [64], Chapter III, give the period relations and the Jacobian with the symplectic picture; Hatcher [80] is the reference for singular (co)homology, the universal coefficient theorem, transfers of coverings (Section 3.G) and Poincare duality (Section 3.3). All chapter and section numbers in this paragraph are recalled pointers, not checked against the books.

The Jacobian as an abelian variety, its universal property, its torsion and Tate modules and the Weil pairing are in Milne's two articles in Cornell-Silverman [130, 129] and in Mumford [138] (Sections 18 to 24); the Picard functor is in [15, Chapter 9]. Etale cohomology and the comparison theorem are in Milne's notes [132]. Correspondences and the Hecke correspondences on modular curves are in Shimura [180], Chapter 7, and Diamond and Shurman [52], Section 6.3; the self-adjointness argument of Corollary 8.82 is the one used by Darmon, Diamond and Taylor [38, Section 4.4]; Diamond, Flach and Guo state the corresponding facts without proof [49, Sections 1.6.1 and 1.8.2] (checked: Proposition 1.3 there makes the Hecke action compatible with their duality morphisms, and Section 1.8.2 says that "the Hecke operators are self-adjoint with respect to the pairing of (25)"). The saturation criterion and the cup product on $\varphi^* H^1(E)$ (Proposition 8.70) are elementary once Theorem 8.60 and Lemma 8.69 are available; compare Agashe, Ribet and Stein [3, Section 3] (section not verified) for the modular degree and optimal quotients. Section numbers for Milne, Mumford, Shimura and Diamond-Shurman are recalled pointers. The genera and modular degrees quoted were computed with PARI/GP [148] and Cremona's tables [35].

Three choices differ from some sources. The cup product is $\int \theta \wedge \eta$ with the complex orientation; the sign of Poincare duality and of the Weil pairing then differ from some books, but the paper uses only sign-invariant properties. The adjoint of an operator is $A^\dagger$, the star being reserved for pullbacks. And the transfer $\varphi^!$ and the pushforward φ_* on H^1 are defined topologically, with the trace of forms as a computational device (Proposition 8.62), rather than through sheaf cohomology.

Chapter 9

Elliptic curves over fields

Every object in the paper is built from an elliptic curve $E/\mathbb{Q}$: its Weierstrass invariants and $v_q(j_E)$, its torsion points and isogenies, its Tate module $T_\ell E$ with the Galois representation $\rho_{E,\ell}$, the numbers a_p and the roots α, β of $X^2 - a_p X + p$, its quadratic twists, its period lattice, its 3-division polynomial. This chapter develops these objects over an arbitrary field, then over $\mathbb{C}$, over finite fields and over $\mathbb{Q}$, proving what the paper uses and stating the deep theorems (Mordell-Weil, Mazur, Kenku, Faltings, Deuring, modularity) precisely with references. It uses Chapter 1 (finite abelian groups, GL_2, inverse limits), Chapter 2 (finite fields, quadratic characters), Chapter 4 (twists, contragredients, adjoints), Chapter 5 (Galois theory of polynomials, profinite groups), Chapter 6 (Frobenius elements, imaginary quadratic orders), and above all Chapter 8 (curves, divisors, Riemann-Roch, Weierstrass models, morphisms and their degree, the Abel-Jacobi theorem). Local questions (minimal models, reduction types, the Tate curve) are Chapter 10; the images of the Galois representations are Chapter 11.

Core results at a glance

Throughout, K is a field, $\bar{K}$ an algebraic closure, $G_K = \mathrm{Gal}(K^{\mathrm{sep}}/K)$, E an elliptic curve over K given by a Weierstrass equation, and $\ell \neq \mathrm{char}\, K$ a prime.

9.1 Conventions. Elliptic curves are Weierstrass cubics with $O = [0:1:0]$; over $\mathbb{Q}$, global minimal models as in Cremona's tables; χ_d is the character of $K(\sqrt{d})$, χ_{q^*} the quadratic character of conductor q (never χ_q), χ_ℓ the cyclotomic character; e_m is Silverman's Weil pairing. Convention 9.1.

9.2 Weierstrass invariants (definition): b_2, b_4, b_6, b_8, $c_4 = b_2^2 - 24b_4$, $c_6 = -b_2^3 + 36b_2b_4 - 216b_6$, Δ, $j = c_4^3/\Delta$, $\omega = dx/(2y + a_1x + a_3)$. Definition 9.2.

9.3 Identities. $4b_8 = b_2b_6 - b_4^2$, $1728\Delta = c_4^3 - c_6^2$; $(2y + a_1x + a_3)^2 = 4x^3 + b_2x^2 + 2b_4x + b_6$, a cubic of discriminant 16Δ; for $\mathrm{char}\, K \neq 2, 3$ the short form $Y^2 = X^3 - 27c_4X - 54c_6$. *(proved here)* Lemma 9.3.

9.4 Smoothness. A Weierstrass cubic is smooth iff $\Delta \neq 0$; if $\Delta = 0$ it has one singular point, a node if $c_4 \neq 0$, a cusp if $c_4 = 0$; every elliptic curve is a smooth Weierstrass cubic. *(proved here for* $\mathrm{char}\, K \neq 2$*; reference in characteristic* 2*)* Proposition 9.4.

9.5 Changes of coordinates. $x = u^2x' + r$, $y = u^3y' + su^2x' + t$ give $u^4c_4' = c_4$, $u^6c_6' = c_6$, $u^{12}\Delta' = \Delta$, $j' = j$, $\omega' = u\omega$; every isomorphism fixing O is of this form; over $\mathbb{Q}$, $v_q(j) = 3v_q(c_4) - v_q(\Delta)$ is independent of the model and $v_q(\Delta)$ changes by multiples of 12. *(proved here)* Proposition 9.5.

9.6 The j-invariant. Curves are isomorphic over $\bar{K}$ iff they have the same j; every $j_0 \in K$ occurs. *(proved here for* $\operatorname{char} K \neq 2, 3$*; reference in general)* Theorem 9.6.

9.7 Automorphisms. For $\operatorname{char} K \neq 2, 3$, $\#\operatorname{Aut}_{\bar{K}}(E) = 2, 4, 6$ for $j \neq 0, 1728$, $j = 1728$, $j = 0$; $[-1](x, y) = (x, -y - a_1x - a_3)$. *(proved here)* Proposition 9.7.

9.8 The chord-tangent law (construction): $P+Q+R = O$ for the three intersections of a line; explicit formulas for $P_1 + P_2$ and $x(2P) = (x^4 - b_4x^2 - 2b_6x - b_8)/(4x^3 + b_2x^2 + 2b_4x + b_6)$; for $\operatorname{char} K \neq 2$, $\#E[2] = 4$. *(proved here)* Construction 9.10, Proposition 9.11.

9.9 Chord-tangent $= \operatorname{Pic}^0$. $P \mapsto [(P) - (O)]$ is additive for the chord-tangent law. *(proved here, given Chapter 8)* Proposition 9.12.

9.10 The group law. $E(\bar{K})$ is an abelian group, $E(L)$ a subgroup for $K \subseteq L \subseteq \bar{K}$, G_K acts by automorphisms, addition and translations are morphisms. *(proved here; the morphism property at the excluded points by reference)* Theorem 9.13.

9.11 Principal divisors. $\sum n_P(P)$ is principal iff $\sum n_P = 0$ and $\sum [n_P]P = O$. *(proved here)* Corollary 9.14.

9.12 The invariant differential. $\operatorname{div}\omega = 0$, $\tau_Q^*\omega = \omega$, $(\varphi + \psi)^*\omega = \varphi^*\omega + \psi^*\omega$, $[m]^*\omega = m\omega$. *(proved here, in every characteristic; one polynomial identity checked by machine; a second proof in characteristic* 0 *in Remark 9.54)* Proposition 9.15.

9.13 Isogenies (definition): morphisms with $\varphi(O) = O$; degree $[\bar{K}(E_1) : \varphi^*\bar{K}(E_2)]$; isogenous over K. Definition 9.17.

9.14 First properties. Isogenies are 0 or surjective; Hom is a group, deg is multiplicative; $[m] \neq 0$ for $m \neq 0$, so Hom is torsion-free. *(proved here; characteristic* 2 *by reference)* Proposition 9.18.

9.15 Kernels. Isogenies are homomorphisms; $\#\ker\varphi = \deg_s\varphi$; a separable isogeny is unramified, with $\#\ker\varphi = \deg\varphi$ and Galois function field extension with group $\ker\varphi$. *(proof sketched here)* Theorem 9.19.

9.16 Quotients. For a finite subgroup H there is a separable $E \to E/H$ with kernel H, over K if H is G_K-stable (Vélu); an isogeny factors through any separable isogeny whose kernel is contained in its kernel. *(stated; reference)* Theorem 9.20.

9.17 The dual isogeny. $\hat{\varphi} \circ \varphi = [\deg\varphi]$, $\varphi \circ \hat{\varphi} = [\deg\varphi]$, $\widehat{\varphi + \psi} = \hat{\varphi} + \hat{\psi}$, $\widehat{[m]} = [m]$, $\deg\hat{\varphi} = \deg\varphi$; deg is a positive definite quadratic form on Hom. *(proof sketched here)* Theorem 9.21.

9.18 Torsion. $\deg[m] = m^2$; if $\operatorname{char} K \nmid m$, $[m]$ is separable and $E[m] \simeq (\mathbb{Z}/m)^2$; in characteristic p, $E[p^e]$ is 0 or $\mathbb{Z}/p^e$. *(proved here, given Theorem 9.21; the last statement stated, reference)* Corollary 9.22.

9.19 Cyclic factorisation (char $K = 0$). $\ker\varphi \simeq \mathbb{Z}/a \times \mathbb{Z}/ab$ and $\varphi = \psi \circ [a]$ with ψ cyclic over K; a cyclic n-isogeny over K has G_K-stable kernels of every order $d \mid n$, and factors into cyclic isogenies of prime degree over K. *(proved here)* Proposition 9.23.

9.20 Division polynomials (definition): $\psi_2 = 2y + a_1x + a_3$, $\psi_3 = 3x^4 + b_2x^3 + 3b_4x^2 + 3b_6x + b_8$, ψ_4, and the recursions. Definition 9.25.

9.21 Degrees. For odd m, $\psi_m \in \mathbb{Z}[a_i][x]$ has degree $(m^2-1)/2$ and leading coefficient m; for even m, ψ_m/ψ_2 has degree $(m^2-4)/2$ and leading coefficient $m/2$. *(proved here)* Proposition 9.26.

9.22 Multiplication by m. For $\operatorname{char} K \nmid m$: $mP = O$ iff $\psi_m(P) = 0$, and $x(mP) = x - \psi_{m-1}\psi_{m+1}/\psi_m^2$. *(proof sketched here)* Theorem 9.27.

9.23 Roots of ψ_m. For odd m, $\operatorname{char} K \nmid m$: the roots of ψ_m are the $(m^2-1)/2$ distinct values $x(P)$, $P \in E[m] \smallsetminus \{O\}$, G_K-equivariantly. *(proved here, given Theorem 9.27)* Corollary 9.28.

9.24 The 3-division polynomial. $x(2P) - x(P) = -\psi_3/\psi_2^2$; for $\operatorname{char} K \neq 2, 3$ the four roots of ψ_3 are the x-coordinates of the four lines of $E[3]$, G_K-equivariantly, so the factorisation pattern of ψ_3 is the orbit pattern of $\bar\rho_{E,3}(G_K)$ on $\mathbb{P}^1(\mathbb{F}_3)$, and a root in K means a K-rational 3-isogeny; over $\mathbb{Q}$, $\operatorname{disc}\psi_3 \in -3(\mathbb{Q}^\times)^2$. *(proved here)* Proposition 9.29.

9.25 The Weil pairing. $e_m\colon E[m] \times E[m] \to \mu_m$ is bilinear, alternating, nondegenerate, Galois-equivariant, compatible in m, and $e_m(S, \hat\varphi T) = e_m(\varphi S, T)$. *(proof sketched here)* Theorem 9.32.

9.26 The determinant. G_K acts on $E[m]$ with determinant χ_m^{cyc}; $E[m] \subseteq E(K)$ forces $\mu_m \subseteq K$; for a stable line $L \subset E[\ell]$, $E[\ell]/L \simeq \operatorname{Hom}(L, \mu_\ell)$, so a rational point of order ℓ gives $0 \to \mathbb{Z}/\ell \to E[\ell] \to \mu_\ell \to 0$. *(proved here)* Corollary 9.33.

9.27 Tate modules (definition and structure): $T_\ell E = \varprojlim E[\ell^n]$ is free of rank 2 over $\mathbb{Z}_\ell$, $T_\ell E/\ell^n = E[\ell^n]$, $V_\ell E/T_\ell E = E[\ell^\infty]$; the Weil pairings give a perfect alternating G_K-equivariant $e\colon T_\ell E \times T_\ell E \to \mathbb{Z}_\ell(1)$; in characteristic p, T_pE is 0 or $\mathbb{Z}_p$. *(proved here; the last statement stated, reference)* Definition 9.34, Proposition 9.35.

9.28 The Galois representations (definition and properties): $\rho_{E,\ell}\colon G_K \to \mathrm{GL}_2(\mathbb{Z}_\ell)$, $\bar\rho_{E,\ell}$ on $E[\ell]$, $\rho \bmod \ell^k$ on $E[\ell^k]$; continuous, $\det\rho_{E,\ell} = \chi_\ell$; an isogeny over K gives $T_\ell E \hookrightarrow T_\ell E'$ with cokernel $(\ker\varphi)[\ell^\infty]$, so $V_\ell E \simeq V_\ell E'$, and $T_\ell E \simeq T_\ell E'$ if $\ell \nmid \deg\varphi$. *(proved here)* Definition 9.36, Proposition 9.37.

9.29 Self-duality. $T_\ell E \simeq (T_\ell E)^\vee(1)$, so $H^1(E, \mathbb{Z}_\ell) = (T_\ell E)^\vee \simeq T_\ell E(-1)$ and ad^0 of $T_\ell E$ and of its dual agree. *(proved here)* Corollary 9.38.

9.30 Complex conjugation. For $E/\mathbb{Q}$ and ℓ odd, $\rho_{E,\ell}(c) \sim \operatorname{diag}(1, -1)$: eigenvalues ±1, trace 0, determinant -1. *(proved here)* Corollary 9.39.

9.31 Frobenius conventions. Frob_p arithmetic; $\rho_{E,\ell}(\mathrm{Frob}_p)$ has eigenvalues α_p, β_p; at good p, $L_p(E,s) = \det(1 - \mathrm{Frob}_p\, p^{-s} \mid V_\ell E)^{-1} = L_p(V_\ell E^\vee, s)$ and $L_p(V_\ell E, s) = L_p(E, s+1)$, with L-factors defined by the geometric Frobenius. Convention 9.40.

9.32 Endomorphism rings. $\mathrm{End}_{\bar{K}}(E)$ is $\mathbb{Z}$, an order in an imaginary quadratic field, or (characteristic p only) a maximal order in the quaternion algebra ramified at p, ∞. *(stated; reference)* Theorem 9.42.

9.33 Normalised endomorphisms. In characteristic 0, $\alpha \mapsto c_\alpha$ ($\alpha^*\omega = c_\alpha\omega$) embeds $\mathrm{End}(E)$ in $\bar{K}$; $\mathrm{End}_{\mathbb{Q}}(E) = \mathbb{Z}$; for $E/\mathbb{Q}$ with CM by $\mathcal{O} \subset F$, $\sigma[c]\sigma^{-1} = [\sigma(c)]$, endomorphisms are defined over F, and $\rho(\sigma)[c]_\ell\rho(\sigma)^{-1} = [\sigma c]_\ell$. *(proved here, given Proposition 9.15 and Theorem 9.42)* Proposition 9.43.

9.34 Complex multiplication (definition): $\mathrm{End}_{\bar{K}}(E) \neq \mathbb{Z}$; it is an isogeny invariant. *(the invariance proved here)* Definition 9.44, Lemma 9.45.

9.35 The thirteen CM j-invariants. $E/\mathbb{Q}$ with CM by $\mathcal{O}$ has $h(\mathcal{O}) = 1$, $D_{\mathcal{O}}$ is one of -3, -4, -7, -8, -11, -12, -16, -19, -27, -28, -43, -67, -163, and $j(E)$ is the corresponding value of the table. *(stated; reference)* Theorem 9.46.

9.36 CM and a_p. For $E/\mathbb{Q}$ with CM by F: $\rho \simeq \rho\otimes\chi_F$; $a_p = 0$ at good p inert in F; $a_p = \pi_p + \bar{\pi}_p$ with $\pi_p\bar{\pi}_p = p$ at good split p; every prime ramified in F divides N (so CM by $\mathbb{Q}(\sqrt{\ell^*})$ forces $\ell \mid N$); conversely $a_p = 0$ at almost all inert p forces CM by F. *(proof sketched here; (i), (ii), (iv) proved in Chapter 6)* Theorem 9.47.

9.37 Lattice sums. $\sum'|\omega|^{-s} < \infty$ for $s > 2$; G_{2k}, $g_2 = 60G_4$, $g_3 = 140G_6$, $\Delta(\Lambda)$, $j(\Lambda)$ are homogeneous of weights $2k, 4, 6, 12, 0$. *(proved here)* Definition 9.50, Lemma 9.51.

9.38 The Weierstrass function. $\wp$ is even, Λ-periodic, with double poles at Λ; $\wp = z^{-2} + \sum(2k+1)G_{2k+2}z^{2k}$; $\wp'^2 = 4\wp^3 - g_2\wp - g_3$; $\Delta(\Lambda) \neq 0$; periodic functions with poles of order ≤ 2 (resp. ≤ 3) at Λ only are $a\wp + b$ (resp. $a\wp' + b\wp + c$). *(proved here)* Theorem 9.52.

9.39 Uniformisation. $z \mapsto (\wp, \wp')$ is a biholomorphic group isomorphism $\mathbb{C}/\Lambda \to E_\Lambda(\mathbb{C})$ with $dx/y \leftrightarrow dz$; every $E/\mathbb{C}$ is E_{Λ_E} for its period lattice; for $4A^3 + 27B^2 \neq 0$ there is a unique Λ with $g_2 = -4A$, $g_3 = -4B$. *(proved here, given the Abel-Jacobi theorem of Chapter 8)* Theorem 9.53.

9.40 Maps of tori. Holomorphic maps $\mathbb{C}/\Lambda_1 \to \mathbb{C}/\Lambda_2$ fixing 0 are $z \mapsto \alpha z$, $\alpha\Lambda_1 \subseteq \Lambda_2$, of degree $[\Lambda_2 : \alpha\Lambda_1]$; $E[m] = \frac{1}{m}\Lambda/\Lambda$; $\mathrm{End}(\mathbb{C}/\Lambda)$ is $\mathbb{Z}$ or an imaginary quadratic order, the latter iff τ is imaginary quadratic; $e_m = \zeta^{\det}$ on $\frac{1}{m}\Lambda/\Lambda$. *(proved here; the sign of ζ by reference)* Proposition 9.55.

9.41 Moduli over $\mathbb{C}$. Lattices up to homothety = curves over $\mathbb{C}$ up to isomorphism = $\mathrm{SL}_2(\mathbb{Z})\backslash\mathcal{H}$; $j(\tau)$ is holomorphic and invariant, $j(i) = 1728$, $j(\zeta_3) = 0$; j is a bijection $\mathrm{SL}_2(\mathbb{Z})\backslash\mathcal{H} \to \mathbb{C}$. *(proved here; the bijectivity and the q-expansion in Chapter 12)* Theorem 9.56.

9.42 The period lattice (definition and properties): Λ_E of the Néron differential of the global minimal model; conjugation-stable, rectangular iff $\Delta > 0$; $\mathrm{vol}(\Lambda_E) = \frac{i}{2}\int \omega \wedge \bar{\omega}$; computed by the AGM; commensurable for isogenous curves. *(proof sketched here)* Definition 9.57, Proposition 9.58.

9.43 Frobenius endomorphism (definition and properties): $\pi(x, y) = (x^{\mathfrak{q}}, y^{\mathfrak{q}})$, purely inseparable of degree $\mathfrak{q}$, acting as $\mathrm{Frob}_{\mathfrak{q}}$; $E(\mathbb{F}_{\mathfrak{q}^n}) = \ker(1-\pi^n)$; $1-\pi$ separable, $\#E(\mathbb{F}_{\mathfrak{q}}) = \deg(1-\pi)$; $a_{\mathfrak{q}} = \mathfrak{q} + 1 - \#E(\mathbb{F}_{\mathfrak{q}})$. *(proved here, given Chapter 8)* Definition 9.60, Proposition 9.61.

9.44 Hasse. $|a_{\mathfrak{q}}| \le 2\sqrt{\mathfrak{q}}$. *(proved here)* Theorem 9.62.

9.45 Characteristic polynomial. $\det \varphi_\ell = \deg \varphi$ on $T_\ell E$; π_ℓ has characteristic polynomial $X^2 - a_{\mathfrak{q}} X + \mathfrak{q}$, roots α, β with $\alpha\beta = \mathfrak{q}$, $|\alpha| = |\beta| = \sqrt{\mathfrak{q}}$; $\#E(\mathbb{F}_{\mathfrak{q}^n}) = \mathfrak{q}^n + 1 - \alpha^n - \beta^n$; the zeta function. *(proved here)* Theorem 9.63.

9.46 Supersingular curves (definition and criteria): $E[p] = 0$; iff $p \mid a_{\mathfrak{q}}$; for $\mathfrak{q} = p \ge 5$ iff $a_p = 0$. *(the first criterion stated, reference; the second proved here)* Definition 9.64, Proposition 9.65.

9.47 Twists over $\mathbb{F}_{\mathfrak{q}}$. $a_{\mathfrak{q}}(E^{\mathrm{tw}}) = -a_{\mathfrak{q}}(E)$ and $(\mathfrak{q}+1)^2 - a_{\mathfrak{q}}^2 = \#E(\mathbb{F}_{\mathfrak{q}})\#E^{\mathrm{tw}}(\mathbb{F}_{\mathfrak{q}})$. *(proved here)* Proposition 9.66.

9.48 Good reduction. For $E/\mathbb{Q}$ good at $p \neq \ell$: $\rho_{E,\ell}$ is unramified at p and $\rho_{E,\ell}(\mathrm{Frob}_p)$ has characteristic polynomial $X^2 - a_p X + p$; $\operatorname{tr} \bar{\rho}_{E,\ell}(\mathrm{Frob}_p) \equiv a_p$. *(proof sketched here, using Chapter 10)* Theorem 9.67.

9.49 Mordell-Weil. $E(\mathbb{Q}) \simeq \mathbb{Z}^r \oplus E(\mathbb{Q})_{\mathrm{tors}}$. *(stated; reference)* Theorem 9.70.

9.50 Torsion and reduction. Reduction is injective on prime-to-p torsion at good p (on all torsion if $p \ge 3$); Nagell-Lutz; $E(\mathbb{Q})_{\mathrm{tors}}$ of `11a1`, `20a1`. *(stated, reference; the examples proved here)* Proposition 9.71.

9.51 Mazur's torsion theorem. $E(\mathbb{Q})_{\mathrm{tors}}$ is $\mathbb{Z}/n$, $n \le 10$ or 12, or $\mathbb{Z}/2 \times \mathbb{Z}/2n$, $n \le 4$. *(stated; reference)* Theorem 9.72.

9.52 Isogeny classes (definition and properties): an equivalence relation; isogenous curves have the same V_ℓ, a_p, L-function, rank and conductor; Faltings's converse; at most 8 curves (Kenku). *(the first two proved here, except the conductor; the rest stated, reference)* Definition 9.73, Theorem 9.74.

9.53 Rational ℓ-isogenies. K-rational ℓ-isogenies $\leftrightarrow$ G_K-stable lines of $E[\ell]$; $E[\ell]$ reducible iff a rational ℓ-isogeny exists; then the two characters multiply to $\bar{\chi}_\ell$. *(proved here, given Theorem 9.20)* Proposition 9.75.

9.54 Mazur and Kenku. Rational ℓ-isogenies only for $\ell = 2$, 3, 5, 7, 11, 13, 17, 19, 37, 43, 67, 163; cyclic n-isogenies only for $n \le 19$ or $n = 21$, 25, 27, 37, 43, 67, 163, with 19, 27, 43, 67, 163 only for CM curves. *(stated; reference)* Theorem 9.76.

9.55 $\mathbb{Z}/\ell \oplus \mu_\ell$. With a rational point of order ℓ (odd), $\bar{\rho} = \left(\begin{smallmatrix} 1 & * \\ 0 & \bar{\chi}_\ell \end{smallmatrix}\right)$; splitting $\Leftrightarrow$ image $\{\mathrm{diag}(1,d)\}$ $\Leftrightarrow$ two rational ℓ-isogenies; $a_p \equiv 1 + p \pmod{\ell}$. *(proved here)* Proposition 9.77.

9.56 No point of order 9 (the paper's Proposition prop:no9). A non-CM $E/\mathbb{Q}$ with $E[3] \simeq \mathbb{Z}/3 \oplus \mu_3$ has no rational point of order 9; so $v_3(\#E(\mathbb{Q})_{\mathrm{tors}}) + [E[3] \simeq \mathbb{Z}/3 \oplus \mu_3] \le 2$. *(proved here, given Theorem 9.76)* Proposition 9.78.

9.57 Isogenies prime to ℓ. If $E[\ell]$ is irreducible, every rational isogeny is $\psi \circ [a]$ with ψ cyclic of degree prime to ℓ; all curves of the class have isomorphic T_ℓ, the same $\mathrm{ad}^0 T_\ell$ and h_ℓ, and the same $t_\ell(E,q)$. *(proved here; the last statement sketched, using Chapter 10)* Lemma 9.80.

9.58 Trivial isogeny classes. Then $E[\ell]$ is irreducible for every ℓ and E is optimal. *(proved here)* Corollary 9.81.

9.59 Quadratic twists (definition and properties): $E^{(d)}\colon y^2 = x^3 + da_2x^2 + d^2a_4x + d^3a_6$, for a general model $Y^2 = X^3 + db_2X^2 + 8d^2b_4X + 16d^3b_6$; depends on d modulo squares; $\psi\colon E^{(d)} \to E$ over $K(\sqrt{d})$ with $\psi^\sigma = [\chi_d(\sigma)]\psi$; the twisted Galois action. *(proved here; the classification of all twists stated)* Definition 9.83, Proposition 9.84.

9.60 Invariants of twists. d^2c_4, d^3c_6, $d^6\Delta$, same j; conversely equal $j \neq 0, 1728$ means a quadratic twist by $d = c_6'c_4/(c_6c_4')$; the twists by q and q^* differ by the twist by -1. *(proved here)* Proposition 9.85.

9.61 Galois representation of a twist. $\rho_{E^{(d)},\ell} \simeq \rho_{E,\ell} \otimes \chi_d$; same ad^0, same det, same $E[2]$, irreducibility preserved. *(proved here)* Theorem 9.86.

9.62 a_p of a twist. $a_p(E^{(d)}) = \chi_d(p)a_p(E)$ for good $p \nmid D$. *(proved here)* Corollary 9.87.

9.63 The twist of good reduction. At a type I_0^* prime q, $E' = E^{(q^*)}$ is good at q, $V_\ell E \simeq V_\ell E' \otimes \chi_{q^*}$, and $a_q(E')^2$ does not depend on the choice of twist. *(proved here, given Chapter 10)* Proposition 9.88.

9.64 Composite twists (definition): $\chi_S = \prod_{q\in S}\chi_{q^*}$, $E_S = E^{(d_S)}$, $d_S = \prod q^*$; $a_p(E_S) = \chi_S(p)a_p(E)$. Definition 9.89.

9.65 What a twist changes. j, t_ℓ, $\mathrm{ad}^0\,\rho$ are twist-invariant; $e_\ell(E,q)$ is invariant only under twists unramified at q. Remark 9.90.

9.66 The L-function (definition and properties): $L(E,s) = \prod_{p\nmid N}(1-a_pp^{-s}+p^{1-2s})^{-1}\prod_{p|N}(1-a_pp^{-s})^{-1}$, absolutely convergent for $\mathrm{Re}\,s > 3/2$, with multiplicative coefficients and the recursion $a_{p^{k+1}} = a_pa_{p^k} - pa_{p^{k-1}}$; continuation and functional equation by modularity. *(proved here, except (iv): stated, reference)* Definition 9.93, Proposition 9.94.

9.67 Labels. Cremona's $N\,c\,k$, curve 1 optimal except in `990h`; LMFDB labels differ. Convention 9.95, Example 9.96.

Where the paper uses this chapter

- **Section 1.1** ($V = V_\ell E$, $T = T_\ell E$, ρ, $\bar\rho$, the Frobenius conventions): Definition 9.34, Proposition 9.35, Definition 9.36, Proposition 9.37, Convention 9.40, Paper link 9.41.
- **Definition def:terms** (j_E, $v_q(j_E)$, the twist-invariance of t_ℓ and the failure for e_ℓ): Proposition 9.5(iii), Paper link 9.9, Remark 9.90.
- **The table of Section 1 and Lemma lem:euler** (the twist E' of good reduction at a type I_0^* prime, α,β with $\alpha\beta = q$, $\alpha+\beta = a_q(E')$, $V = V'\otimes\chi_{q^*}$, $\mathrm{ad}^0\,V = \mathrm{ad}^0\,V'$): Theorem 9.63, Proposition 9.66, Theorem 9.86, Proposition 9.88, Paper link 9.69, Paper link 9.92.
- **Lemma lem:twist (ii)** (the model and the invariants $(q^*)^2c_4$, $(q^*)^3c_6$, $(q^*)^6\Delta$ of the twist; $v_q(\Delta)$ modulo 12): Definition 9.83, Proposition 9.85, Proposition 9.5(iii), Warning 9.91.
- **Section 1.4** (the twist-symmetrised weight $w_\ell(E,q)$, which compares E with its twist by χ_{q^*}; the paper writes this twist $E^{(q)}$, the book $E^{(q^*)}$): Definition 9.83(c), Proposition 9.85(iii), Warning 9.91(a).

- **Theorems thm:twist and thm:quant** (E_S, χ_S, $a_p(f) = \chi_S(p)a_p(g)$, irreducibility of $\bar\rho \otimes \chi_S$): Definition 9.89, Theorem 9.86, Corollary 9.87.
- **Theorem thm:qual and the Example of Section 3** (ex:qual: twists of `121a1`, `539c1`, `980i1`; labels; a_p): Corollary 9.87, Warning 9.91, Example 9.68, Example 9.96.
- **Lemma lem:h0** (complex conjugation with eigenvalues ± 1, $\det\rho = \chi_\ell$, $\bar\chi_3 = \chi_{-3}$): Corollary 9.39, Proposition 9.37, Theorem 9.47, Warning 9.48.
- **Proposition prop:ns** (the 3-division polynomial, $\det\bar\rho_{E,3} = \chi_{-3}$, complex conjugation): Proposition 9.29, Example 9.30, Corollary 9.33, Corollary 9.39, Paper link 9.31.

9.1 Weierstrass equations and their invariants

Every elliptic curve in the paper is given by a Weierstrass equation, in the form that PARI's `ellinit` expects, and every local quantity the paper reads off at a bad prime q starts from the invariants c_4, c_6, Δ and j of such an equation. This section defines them, proves that a Weierstrass cubic is smooth exactly when $\Delta \neq 0$, records how the invariants change under a change of coordinates, and proves that j classifies curves over an algebraically closed field. The paper uses these facts in Definition def:terms (the valuation $v_q(j_E)$, which must not depend on the model), in the proof of Lemma lem:twist (ii) (the invariants of a twisted model, and the rule that $v_q(\Delta)$ changes by multiples of 12), and in its appendix (`valuation(E.j, q)`).

Convention 9.1 (conventions of this chapter)**.**

(a) *Fields and curves.* K is a field, $\bar K$ a fixed algebraic closure, K^{sep} the separable closure in it and $G_K = \mathrm{Gal}(K^{\mathrm{sep}}/K)$. An *elliptic curve over* K is a pair (E, O) of a smooth projective curve E of genus one over K and a point $O \in E(K)$. By Chapter 8 (the theorem

that a genus-one curve with a rational point is a Weierstrass cubic) every elliptic curve is isomorphic to a smooth Weierstrass cubic with $O \mapsto [0:1:0]$, and we always work with such a model. Whenever a prime ℓ appears, $\ell \neq \operatorname{char} K$.

(b) *Over* $\mathbb{Q}$. "$E/\mathbb{Q}$" means a curve given by a Weierstrass equation with rational coefficients; from Section 9.9 on, by its global minimal model (Chapter 10), which is the model printed in Cremona's tables [35, 36]. Such models have $a_1, a_3 \neq 0$ in general (`121a1`, `726a1`, `99a1`), so "a model" always means a general Weierstrass equation.

(c) *Letters.* p, q, ℓ are primes; as in the paper, q is usually a bad prime of $E/\mathbb{Q}$, p any prime and ℓ the coefficient prime. The number of elements of a finite field that need not be prime is written $\mathfrak{q} = p^r$ (Section 9.8); for $\mathbb{F}_p$ we write a_p. In two places only, Theorem 9.56(iii) and the last sentence of Example 9.68, $q = e^{2\pi i\tau}$ is the variable of q-expansions, as in Chapter 12; no prime q occurs there.

(d) *Characters.* For $d \in K^\times$ and $\operatorname{char} K \neq 2$, $\chi_d\colon G_K \to \{\pm 1\}$ is the character of $K(\sqrt{d})/K$: $\sigma(\sqrt{d}) = \chi_d(\sigma)\sqrt{d}$. For $K = \mathbb{Q}$ and d not a square, $\chi_d(\mathrm{Frob}_p) = \left(\frac{D}{p}\right)$ (Kronecker symbol) for $p \nmid D$, where D is the discriminant of $\mathbb{Q}(\sqrt{d})$ (Chapters 2 and 6). For an odd prime q, $q^* = (-1)^{(q-1)/2}q$ and χ_{q^*} is the quadratic character of conductor q. The paper's χ_q is written χ_{q^*}; the symbol χ_ℓ with a letter subscript is the ℓ-adic cyclotomic character, $\sigma(\zeta) = \zeta^{\chi_\ell(\sigma)}$ on μ_{ℓ^∞}, and $\bar{\chi}_\ell$ is its reduction modulo ℓ; at a numerical prime we write χ_3^{cyc}, so that $\bar{\chi}_3 = \chi_{-3}$. For an integer m prime to $\operatorname{char} K$, $\chi_m^{\mathrm{cyc}}\colon G_K \to (\mathbb{Z}/m)^\times$ is defined by $\sigma(\zeta) = \zeta^{\chi_m^{\mathrm{cyc}}(\sigma)}$ for $\zeta \in \mu_m$.

(e) *Labels.* Cremona's labels are written as the paper writes them: `11a1` is a curve, `121c` an isogeny class. The capital letters of Cremona's book and of [3] (`99A1`) denote the same classes as the lower-case letters of the data files. LMFDB labels are written `11.a2` (Section 9.12).

(f) *The Weil pairing* is Silverman's e_m [185, Section III.8]. Some books use its inverse; the only statement of this chapter that depends on the choice is the comparison with $e^{2\pi i/m}$ over $\mathbb{C}$ in Proposition 9.55(iv).

(g) *Duals and maps.* $M^\vee = \operatorname{Hom}(M, R)$ is the linear dual; φ^* and φ_* are pullback and pushforward along a map φ of curves; $\hat{\varphi}$ is the dual isogeny. Maps of curves are written φ, ψ; the letter ψ_m is also used for division polynomials (Section 9.4), which is never ambiguous in context.

The Frobenius conventions are fixed in Convention 9.40.

Definition 9.2 (Weierstrass equations and their invariants)**.** A *Weierstrass equation* over K is

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6, \qquad a_1, a_2, a_3, a_4, a_6 \in K. \tag{9.1}$$

The curve it defines is its projective closure $Y^2Z + a_1XYZ + a_3YZ^2 = X^3 + a_2X^2Z + a_4XZ^2 + a_6Z^3$ in $\mathbb{P}^2$, which has exactly one point on the line $Z = 0$, namely $O = [0:1:0]$. Put

$$b_2 = a_1^2 + 4a_2, \qquad b_4 = 2a_4 + a_1a_3, \qquad b_6 = a_3^2 + 4a_6,$$
$$b_8 = a_1^2a_6 + 4a_2a_6 - a_1a_3a_4 + a_2a_3^2 - a_4^2, \qquad c_4 = b_2^2 - 24b_4, \qquad c_6 = -b_2^3 + 36b_2b_4 - 216b_6,$$

$$\Delta = -b_2^2 b_8 - 8b_4^3 - 27b_6^2 + 9b_2 b_4 b_6, \qquad j = \frac{c_4^3}{\Delta} \text{ when } \Delta \neq 0.$$

Δ is the *discriminant* and j the *j-invariant*. The *invariant differential* is

$$\omega = \frac{dx}{2y + a_1 x + a_3} = \frac{dy}{3x^2 + 2a_2 x + a_4 - a_1 y}.$$

The two expressions agree because differentiating (9.1) gives $(2y + a_1x + a_3)\,dy = (3x^2 + 2a_2x + a_4 - a_1y)\,dx$. These are the conventions of [185, Section III.1], and PARI's `ellinit` returns $a_1, \dots, a_6, b_2, b_4, b_6, b_8, c_4, c_6, \Delta, j$ in this order (Chapter 22).

The invariants are less arbitrary than they look. The b_i are what remains after completing the square in y: the equation becomes $(2y + a_1x + a_3)^2 = 4x^3 + b_2x^2 + 2b_4x + b_6$ (Lemma 9.3(ii) below), and $b_8 = (b_2b_6 - b_4^2)/4$, which is a polynomial in the a_i with integer coefficients, is the combination needed to write $\frac{1}{16}$ of the discriminant of this cubic without denominators. The c_4 and c_6 are what remains after also removing the x^2 term, which gives the short form $Y^2 = X^3 - 27c_4X - 54c_6$ (Lemma 9.3(iii)). The discriminant Δ vanishes exactly when the cubic has a repeated root, that is, when the curve is singular (Proposition 9.4), and j is the combination of c_4 and Δ that does not change under any change of coordinates (Proposition 9.5). The point of working with the general equation, and not only with short models, is that over $\mathbb{Q}$ the global minimal models of Cremona's tables, which the paper uses, often have $a_1, a_3 \neq 0$, and the short form is not available in characteristics 2 and 3, which matter for reduction modulo 2 and 3 (Chapter 10).

For a first example take $y^2 = x^3 - x$, so $a_1 = a_2 = a_3 = a_6 = 0$ and $a_4 = -1$. Then $b_2 = 0$, $b_4 = -2$, $b_6 = 0$, $b_8 = -1$, so $c_4 = -24b_4 = 48$, $c_6 = 0$, $\Delta = -8b_4^3 = 64$ and $j = 48^3/64 = 1728$. The cubic $4x^3 - 4x$ has the three roots $0, \pm 1$, and its discriminant is $16 \cdot 64 = 1024 = 4^4 \cdot (0-1)^2(0+1)^2(1+1)^2$, in accordance with Lemma 9.3(ii).

Lemma 9.3 (identities)**.** *For every Weierstrass equation:*

(i) $4b_8 = b_2b_6 - b_4^2$ *and* $1728\Delta = c_4^3 - c_6^2$.

(ii) (Completing the square.) With $\eta = 2y + a_1x + a_3$ *the equation* (9.1) *is equivalent, when* $\operatorname{char} K \neq 2$*, to*

$$\eta^2 = 4x^3 + b_2x^2 + 2b_4x + b_6.$$

The cubic on the right is written $F(x)$ below; its discriminant (as a polynomial in x) is 16Δ.

(iii) (Short form.) If $\operatorname{char} K \neq 2, 3$*, the substitution* $X = 36x + 3b_2$, $Y = 108(2y + a_1x + a_3)$ *transforms* (9.1) *into*

$$Y^2 = X^3 - 27c_4X - 54c_6.$$

Proof. All three are identities between polynomials in $a_1, \dots, a_6$ (and x, y). (i) Expanding $b_2b_6 - b_4^2 = (a_1^2 + 4a_2)(a_3^2 + 4a_6) - (2a_4 + a_1a_3)^2$ gives $a_1^2a_3^2 + 4a_1^2a_6 + 4a_2a_3^2 + 16a_2a_6 - 4a_4^2 - 4a_1a_3a_4 - a_1^2a_3^2$, which is $4b_8$. For the second identity expand both cubes as polynomials in b_2, b_4, b_6: the terms b_2^6 and $b_2^4b_4$ cancel, and

$$\begin{aligned} c_4^3 - c_6^2 &= 432b_2^2b_4^2 - 432b_2^3b_6 - 13824b_4^3 + 15552b_2b_4b_6 - 46656b_6^2 \\ &= 1728\Big(-\tfrac{1}{4}b_2^2(b_2b_6 - b_4^2) - 8b_4^3 - 27b_6^2 + 9b_2b_4b_6\Big), \end{aligned}$$

which is 1728Δ by the first identity. (ii) $\eta^2 = 4y^2 + 4a_1xy + 4a_3y + (a_1x + a_3)^2$, and replacing $4(y^2 + a_1xy + a_3y)$ by $4(x^3 + a_2x^2 + a_4x + a_6)$ gives $4x^3 + (a_1^2 + 4a_2)x^2 + (2a_1a_3 + 4a_4)x + (a_3^2 + 4a_6)$. Conversely, when 2 is invertible, $y = (\eta - a_1x - a_3)/2$ recovers y. The discriminant of $4x^3 + b_2x^2 + 2b_4x + b_6$ is, by the formula for the discriminant of a cubic (Chapter 5), $b_2^2(2b_4)^2 - 4\cdot 4(2b_4)^3 - 4b_2^3b_6 - 27\cdot 16\,b_6^2 + 18\cdot 4\,b_2(2b_4)b_6$, which equals 16Δ after replacing $b_2^2b_4^2 - b_2^3b_6$ by $-4b_2^2b_8$. (iii) Here 2 and 3 are invertible, so $x = (X - 3b_2)/36$ and $\eta = Y/108$ recover the old coordinates, and by (ii) the equation is equivalent to $Y^2 = 108^2F(x)$. Since $108^2 = 11664 = 4\cdot 36^3/16$, one has $108^2\cdot 4x^3 = (X - 3b_2)^3$, $108^2b_2x^2 = 9b_2(X - 3b_2)^2$, $108^2\cdot 2b_4x = 648b_4(X - 3b_2)$ and $108^2b_6 = 11664b_6$. Adding,

$$\begin{aligned} 108^2F(x) &= (X^3 - 9b_2X^2 + 27b_2^2X - 27b_2^3) + (9b_2X^2 - 54b_2^2X + 81b_2^3) \\ &\quad + 648b_4X - 1944b_2b_4 + 11664b_6 \\ &= X^3 - 27(b_2^2 - 24b_4)X + 54(b_2^3 - 36b_2b_4 + 216b_6) = X^3 - 27c_4X - 54c_6. \end{aligned}$$

In the language of Proposition 9.5 this is the change of coordinates with $u = 1/6$, $r = -b_2/12$ (and suitable s, t), since $x = \frac{1}{36}X - \frac{b_2}{12}$ and $Y = 216y + \dots$. Each expansion was also checked by machine (PARI/GP, with $a_1, \dots, a_6$ as indeterminates). □

Proposition 9.4 (smoothness)**.** *Let E be the curve defined by a Weierstrass equation over K.*

(i) The point O is smooth, and E is smooth if and only if $\Delta \neq 0$.

(ii) If $\Delta = 0$, E has exactly one singular point. It is a node *(two distinct tangent lines) if $c_4 \neq 0$ and a* cusp *(one tangent line) if $c_4 = 0$.*

(iii) A smooth Weierstrass cubic, with the point O, is an elliptic curve; every elliptic curve over K is isomorphic over K to one, with its origin going to O.

Proof. (i) That O is smooth is checked in Chapter 8 (the partial derivative of the homogeneous equation with respect to Z is 1 at O). Assume $\operatorname{char} K \neq 2$. By Lemma 9.3(ii) we may use the coordinates (x, η), in which the equation is $G = \eta^2 - F(x) = 0$. A point (x_0, η_0) is singular iff $G = \partial G/\partial\eta = \partial G/\partial x = 0$ there, that is, iff $\eta_0 = 0$ and $F(x_0) = F'(x_0) = 0$, iff x_0 is a double root of F. The cubic F has leading coefficient $4 \neq 0$, roots $r_1, r_2, r_3 \in \bar{K}$, and discriminant $4^4\prod_{i<j}(r_i - r_j)^2$ (Chapter 5); so it has a double root in $\bar{K}$ iff its discriminant 16Δ vanishes, iff $\Delta = 0$ (as $2 \neq 0$ in K). Every point other than O is affine, since O is the only point on $Z = 0$, so this covers all points. In characteristic 2 the statement is [185, Section III.1]; we do not prove it.

(ii) Let S be a singular point; it is the only one, for a line through two singular points would meet the cubic with multiplicity at least 4 and so lie in it (Chapter 8, Bezout), while a Weierstrass cubic is irreducible (Chapter 8). Move S to $(0,0)$ by $x \mapsto x + x_0$, $y \mapsto y + y_0$ (a change of coordinates with $u = 1$, $s = 0$, which by Proposition 9.5 below does not change c_4 or Δ). Since $(0,0)$ lies on the curve and both partial derivatives vanish there, $a_6 = a_4 = a_3 = 0$, and the equation is $y^2 + a_1xy - a_2x^2 = x^3$. Now $b_4 = b_6 = b_8 = 0$, so $\Delta = 0$ and $c_4 = b_2^2 = (a_1^2 + 4a_2)^2$. The tangent lines at $(0,0)$ are the factors of the quadratic part $y^2 + a_1xy - a_2x^2$, which are distinct iff its discriminant $a_1^2 + 4a_2 = b_2$ is nonzero (in characteristic 2: iff $a_1 \neq 0$, iff $b_2 = a_1^2 \neq 0$). So the point is a node iff $c_4 \neq 0$.

(iii) A smooth Weierstrass cubic has genus one and O is a K-point (Chapter 8); the converse is the theorem of Chapter 8 quoted in Convention 9.1(a). □

Proposition 9.5 (changes of coordinates)**.**

(i) For $u \in K^\times$ and $r, s, t \in K$, the substitution

$$x = u^2x' + r, \qquad y = u^3y' + su^2x' + t$$

transforms a Weierstrass equation into a Weierstrass equation, with

$$\begin{aligned} ua_1' &= a_1 + 2s, & u^2a_2' &= a_2 - sa_1 + 3r - s^2, \\ u^3a_3' &= a_3 + ra_1 + 2t, & u^4a_4' &= a_4 - sa_3 + 2ra_2 - (t + rs)a_1 + 3r^2 - 2st, \end{aligned}$$

$$\begin{aligned} u^6a_6' &= a_6 + ra_4 + r^2a_2 + r^3 - ta_3 - t^2 - rta_1, \\ u^2b_2' &= b_2 + 12r, \qquad u^4b_4' = b_4 + rb_2 + 6r^2, \qquad u^6b_6' = b_6 + 2rb_4 + r^2b_2 + 4r^3, \\ u^8b_8' &= b_8 + 3rb_6 + 3r^2b_4 + r^3b_2 + 3r^4, \qquad u^4c_4' = c_4, \qquad u^6c_6' = c_6, \end{aligned}$$

$$u^{12}\Delta' = \Delta, \qquad j' = j, \qquad \omega' = u\,\omega.$$

These substitutions form a group under composition.

(ii) Every isomorphism between two smooth Weierstrass cubics over K that sends O to O is given by such a substitution.

(iii) Let $K = \mathbb{Q}$ and q a prime. For any two models of E, $v_q(\Delta') - v_q(\Delta) \in 12\mathbb{Z}$, and $v_q(j) = 3v_q(c_4) - v_q(\Delta)$ is the same for both. In particular $v_q(j_E)$ depends only on the isomorphism class of E over $\mathbb{Q}$.

Proof. (i) Substitute and compare coefficients: with $W(x, y)$ the left side minus the right side of (9.1) and W' the same for the primed coefficients, one has $W(u^2x' + r, u^3y' + su^2x' + t) = u^6W'(x', y')$, which defines the a_i' and is equivalent to the five formulas displayed. The formulas for the b_i', c_4', c_6', Δ' follow by substitution into Definition 9.2; all were checked by machine with a_i, u, r, s, t indeterminate. Then $j' = c_4'^3/\Delta' = u^{-12}c_4^3/(u^{-12}\Delta) = j$. Finally $dx = u^2dx'$ and $2y + a_1x + a_3 = u^3(2y' + a_1'x' + a_3')$ (from the formulas for a_1' and a_3'), so $\omega = u^{-1}\omega'$. The composite of two substitutions is the substitution with $u = u_1u_2$, $r = r_1 + u_1^2r_2$, $s = s_1 + u_1s_2$, $t = t_1 + u_1^2s_1r_2 + u_1^3t_2$. Indeed, substituting $x' = u_2^2x'' + r_2$, $y' = u_2^3y'' + s_2u_2^2x'' + t_2$ into $x = u_1^2x' + r_1$, $y = u_1^3y' + s_1u_1^2x' + t_1$ gives $x = (u_1u_2)^2x'' + (r_1 + u_1^2r_2)$ and

$$y = (u_1u_2)^3y'' + (s_1 + u_1s_2)(u_1u_2)^2x'' + \big(t_1 + u_1^2s_1r_2 + u_1^3t_2\big),$$

which is of the same shape. With these formulas, composing (u, r, s, t) with the substitution

$$(u^{-1},\ -ru^{-2},\ -su^{-1},\ (rs - t)u^{-3})$$

gives $u = 1$, $r + u^2(-ru^{-2}) = 0$, $s + u(-su^{-1}) = 0$ and $t + u^2s(-ru^{-2}) + u^3(rs - t)u^{-3} = 0$, the identity substitution; so every substitution has an inverse of the same kind.

(ii) Let $\varphi\colon E \to E'$ be such an isomorphism, with coordinates x, y on E and x', y' on E'. By Chapter 8, $\mathcal{L}(2(O))$ has basis $1, x$ and $\mathcal{L}(3(O))$ has basis $1, x, y$, and likewise on E'. Since φ is an isomorphism with $\varphi(O) = O$, φ^*x' has a double pole at O and no other pole, and φ^*y' a triple pole; so $\varphi^*x' = \alpha x + \rho$ and $\varphi^*y' = \beta y + \gamma x + \tau$ with $\alpha, \beta \in K^\times$, $\rho, \gamma, \tau \in K$ (all in K when φ is defined over K). Substituting these into the equation of E' gives a relation among $1, x, y, x^2, xy, y^2, x^3$ in $K(E)$. These seven functions lie in $\mathcal{L}(6(O))$, of dimension 6, and have pole orders $0, 2, 3, 4, 5, 6, 6$ at O; the first six have distinct pole orders and are therefore linearly

independent. So the relations among the seven form a one-dimensional space, spanned by the equation of E (Chapter 8, proof of the Weierstrass form). Comparing the coefficients of y^2 and x^3 gives $\beta^2 = \alpha^3$. Put $u = \alpha/\beta$; then $u^2 = \alpha^2/\beta^2 = \alpha^{-1}$ and $u^3 = \beta^{-1}$, so $x = u^2\varphi^* x' - u^2\rho$ and $y = u^3\varphi^* y' - u^3\gamma x - u^3\tau$, which after substituting x is of the stated form.

(iii) If both models have rational coefficients, $u \in \mathbb{Q}^\times$ and $v_q(\Delta') = v_q(\Delta) - 12v_q(u)$, $v_q(c_4') = v_q(c_4) - 4v_q(u)$; so $3v_q(c_4') - v_q(\Delta') = 3v_q(c_4) - v_q(\Delta)$, which is $v_q(j)$ (with $v_q(0) = +\infty$ when $c_4 = 0$). Here $u \in \mathbb{Q}^\times$ because, by (ii), the isomorphism over $\mathbb{Q}$ between the two models is a substitution with coefficients in $\mathbb{Q}$. □

Part (iii) is what makes $v_q(j_E)$ usable as an invariant of E, while $v_q(\Delta)$ is an invariant only modulo 12: a rescaling with $v_q(u) = -1$ keeps an integral model integral and raises $v_q(\Delta)$ by 12. Choosing, among the integral models, one with the least $v_q(\Delta)$ is the minimal model problem of Chapter 10.

Theorem 9.6 (the j-invariant)**.**

(i) Two elliptic curves over K are isomorphic over $\bar{K}$ if and only if they have the same j-invariant.

(ii) Every $j_0 \in K$ is the j-invariant of an elliptic curve over K: one can take $y^2 + y = x^3$ for $j_0 = 0$ (if $\operatorname{char} K \neq 3$), $y^2 = x^3 + x$ for $j_0 = 1728$ (if $\operatorname{char} K \neq 2$), and

$$y^2 + xy = x^3 - \frac{36}{j_0 - 1728}x - \frac{1}{j_0 - 1728} \qquad (j_0 \neq 0, 1728),$$

which has $c_4 = j_0/(j_0 - 1728)$ and $\Delta = j_0^2/(j_0 - 1728)^3$.

Proof. (i) "Only if" is Proposition 9.5(i). For "if" we give the proof when $\operatorname{char} K \neq 2, 3$; the general case is [185, Appendix A]. By Lemma 9.3(iii) (a change of coordinates with $u = 1/6$) both curves have short models $y^2 = x^3 - 27c_4x - 54c_6$, $y^2 = x^3 - 27c_4'x - 54c_6'$, and the change $(u, 0, 0, 0)$ replaces (c_4, c_6) by $(u^{-4}c_4, u^{-6}c_6)$. So it suffices to find $u \in \bar{K}^\times$ with $c_4 = u^4c_4'$ and $c_6 = u^6c_6'$. If $j = j' = 0$ then $c_4 = c_4' = 0$ and $c_6, c_6' \neq 0$ (as $1728\Delta = -c_6^2$); take u with $u^6 = c_6/c_6'$. If $j = j' = 1728$ then $c_6 = c_6' = 0$ (as $1728\Delta = c_4^3 - c_6^2$ and $j = 1728$ means $c_4^3 = 1728\Delta$); take $u^4 = c_4/c_4'$. Otherwise all of c_4, c_6, c_4', c_6' are nonzero. Choose u with $u^4 = c_4/c_4'$. Then $j = j'$ gives $\Delta/\Delta' = c_4^3/c_4'^3 = u^{12}$, and $c_6^2 = c_4^3 - 1728\Delta = u^{12}(c_4'^3 - 1728\Delta') = u^{12}c_6'^2$, so $c_6 = \pm u^6c_6'$; if the sign is $-$, replace u by iu with $i^2 = -1$, which keeps u^4 and changes the sign of u^6.

(ii) For $y^2 + y = x^3$, $b_2 = b_4 = b_8 = 0$ and $b_6 = 1$, so $(c_4, \Delta) = (0, -27)$; for $y^2 = x^3 + x$, $b_2 = b_6 = 0$, $b_4 = 2$, $b_8 = -1$, so $(c_4, \Delta) = (-48, -64)$. Hence the first curve is smooth exactly when $\operatorname{char} K \neq 3$ and the second exactly when $\operatorname{char} K \neq 2$, with $j = 0$ and $j = (-48)^3/(-64) = 1728$. For the third, put $k = 1/(j_0 - 1728)$, so $a_1 = 1$, $a_2 = a_3 = 0$, $a_4 = -36k$, $a_6 = -k$. Then $b_2 = 1$, $b_4 = -72k$, $b_6 = -4k$, $b_8 = a_1^2a_6 - a_4^2 = -k - 1296k^2$, and

$$c_4 = 1 + 1728k = \frac{j_0}{j_0 - 1728},$$

$$\Delta = k + 1296k^2 - 27 \cdot 16k^2 + 9 \cdot 288k^2 + 8 \cdot 72^3k^3 = k(1 + 1728k)^2 = \frac{j_0^2}{(j_0 - 1728)^3},$$

using $72^3 = 373248$, $8 \cdot 373248 = 1728^2$ and $1296 - 432 + 2592 = 3456 = 2 \cdot 1728$. So $j = c_4^3/\Delta = j_0^3(j_0 - 1728)^{-3} \cdot (j_0 - 1728)^3 j_0^{-2} = j_0$, and $\Delta \neq 0$ because $j_0 \neq 0$. □

Proposition 9.7 (automorphisms)**.** *Let* $\operatorname{char} K \neq 2,3$ *and let* E *be an elliptic curve over* K*. The group* $\operatorname{Aut}_{\bar K}(E)$ *of automorphisms of* E *fixing* O *is cyclic of order* 2 *if* $j \neq 0, 1728$*, of order* 4 *if* $j = 1728$*, and of order* 6 *if* $j = 0$*. On a short model* $y^2 = x^3 + Ax + B$ *the automorphisms are* $(x, y) \mapsto (u^2x, u^3y)$ *with* $u^4A = A$*,* $u^6B = B$*; and* $[-1](x, y) = (x, -y - a_1x - a_3)$ *on a general model.*

Proof. By Proposition 9.5(ii) an automorphism of the short model is a substitution (u, r, s, t) preserving the shape: $a_1' = 0$ forces $s = 0$, then $a_2' = 0$ forces $r = 0$, and then $a_3' = 0$ forces $t = 0$. So it is $(u, 0, 0, 0)$ with $A = u^4A$, $B = u^6B$ (here $x = u^2x'$, so the map $(x', y') \mapsto (x, y)$ is (u^2x', u^3y')). On the short model $b_2 = 0$, $b_4 = 2A$, $b_6 = 4B$, so $c_4 = -48A$, $c_6 = -864B$, $\Delta = -16(4A^3 + 27B^2)$ and

$$j = 1728\,\frac{4A^3}{4A^3 + 27B^2};$$

thus $j = 0$ iff $A = 0$, and $j = 1728$ iff $B = 0$. If $AB \neq 0$ ($j \neq 0, 1728$) the conditions are $u^4 = u^6 = 1$, which mean $u^2 = u^6/u^4 = 1$; if $B = 0$ ($j = 1728$), $u^4 = 1$; if $A = 0$ ($j = 0$), $u^6 = 1$. Distinct u give distinct maps, since $u = u^3/u^2$ is read off the map. So $\operatorname{Aut}_{\bar K}(E) \simeq \mu_n(\bar K)$ with $n = 2, 4, 6$. Since $\operatorname{char} K \nmid n$, the polynomial $X^n - 1$ is separable and $\mu_n(\bar K)$ has n elements; a finite subgroup of $\bar K^\times$ is cyclic (Chapter 1). The formula for $[-1]$ is the substitution $(u, r, s, t) = (-1, 0, -a_1, -a_3)$, which sends (x, y) to the other point with the same x. □

Example 9.8 (the invariants of the running examples)**.** The table lists the global minimal models of Cremona's tables [36] and their invariants, all recomputed from the a-invariants with PARI/GP.

curve	$[a_1, a_2, a_3, a_4, a_6]$	c_4	c_6	Δ	j
`11a1`	$[0, -1, 1, -10, -20]$	$2^4 \cdot 31$	20008	-11^5	$-2^{12}31^3/11^5$
`11a3`	$[0, -1, 1, 0, 0]$	2^4	-152	-11	$-2^{12}/11$
`20a1`	$[0, 1, 0, 4, 4]$	$-2^4 \cdot 11$	-2368	$-2^8 \cdot 5^2$	$2^4 \cdot 11^3/5^2$
`99a1`	$[1, -1, 1, -2, 0]$	3^4	135	$3^3 \cdot 11$	$3^9/11$
`121a1`	$[1, 1, 1, -30, -76]$	$11 \cdot 131$	54703	-11^2	$-11 \cdot 131^3$
`121c1`	$[1, 1, 0, -2, -7]$	11^2	5203	-11^4	-11^2
`121c2`	$[1, 1, 0, -3632, 82757]$	$11^3 \cdot 131$	-72809693	-11^8	$-11 \cdot 131^3$
`121d1`	$[0, -1, 1, -40, -221]$	$2^4 \cdot 11^2$	202312	-11^7	$-2^{12}/11$
`539c1`	$[1, 0, 1, 170, -3237]$	$-7^2 \cdot 167$	2808827	$-7^9 \cdot 11^2$	$167^3/(7^3 \cdot 11^2)$
`726a1`	$[1, 1, 0, -35, -51]$	$5 \cdot 11 \cdot 31$	31339	$2^6 \cdot 3^3 \cdot 11^3$	$5^3 \cdot 31^3/(2^6 \cdot 3^3)$
`980i1`	$[0, 0, 0, 1568, -72716]$	$-2^9 \cdot 3 \cdot 7^2$	62826624	$-2^8 \cdot 5 \cdot 7^{11}$	$2^{19}3^3/(5 \cdot 7^5)$
`77c1`	$[1, 1, 0, 4, 11]$	-167	-8189	$-7^3 \cdot 11^2$	$167^3/(7^3 \cdot 11^2)$
`140b1`	$[0, 0, 0, 32, 212]$	$-2^9 \cdot 3$	-183168	$-2^8 \cdot 5 \cdot 7^5$	$2^{19}3^3/(5 \cdot 7^5)$
`539d1`	$[0, 1, 1, -16, -66]$	$2^4 \cdot 7^2$	52136	$-7^6 \cdot 11$	$-2^{12}/11$

For instance, for `11a1`: $b_2 = -4$, $b_4 = -20$, $b_6 = -79$, $b_8 = -21$, so $c_4 = 16 + 480 = 496$, $c_6 = 64 + 2880 + 17064 = 20008$ and $\Delta = -16 \cdot (-21) + 64000 - 27 \cdot 6241 + 9 \cdot (-4)(-20)(-79) = -161051 = -11^5$. The valuations $v_q(j)$ feed the paper's term $t_\ell(E, q)$: $v_7(j(\texttt{539c1})) = -3$, so $t_3(\texttt{539c1}, 7) = v_3(3) = 1$; $v_7(j(\texttt{980i1})) = -5$, so $t_5(\texttt{980i1}, 7) = 1$; and $v_{11}(j(\texttt{121a1})) = 1 \geq 0$, so $t_\ell(\texttt{121a1}, 11) = 0$. Curves with the same j in the table (`539c1` and `77c1`; `980i1` and `140b1`; `11a3`, `121d1` and `539d1`; `121a1` and `121c2`) are quadratic twists of one another (Section 9.10).

In the paper 9.9. Definition def:terms of the paper defines $t_\ell(E, q) = v_\ell(-v_q(j_E))$ when $v_q(j_E) < 0$. That this is a property of E and not of the chosen equation is Proposition 9.5(iii); the appendix

computes it from `vj = valuation(j, q)` with `j = E.j`. In the proof of Lemma lem:twist (ii) the twisted model "is minimal exactly when the result is less than 12, otherwise 12 is subtracted": that $v_q(\Delta)$ can only change by multiples of 12 is Proposition 9.5(iii), and the minimality criterion itself is Chapter 10.

9.2 The group law

The points of an elliptic curve form an abelian group, and every group the paper writes down is a group of points or a subgroup of one: $E(\mathbb{Q})_{\mathrm{tors}}$ in Conjecture conj:eis, $E[\ell]$ in Section 1.1, $E(\mathbb{F}_q)$ behind the numbers a_q. This section gives the chord-tangent construction with its explicit formulas, identifies it with the group $\mathrm{Pic}^0(E)$ of Chapter 8 (which gives associativity for free), and proves the translation invariance of the invariant differential, which is what makes multiplication by m separable when $\mathrm{char}\, K \nmid m$.

Construction 9.10 (the chord-tangent law)**.** Let E be a smooth Weierstrass cubic over K and $P, Q \in E(\bar{K})$. The line through P and Q (the tangent line at P if $P = Q$) meets E in exactly three points counted with multiplicity (Chapter 8, Bezout); let R be the third. The line through R and O meets E in a third point, which is defined to be $P + Q$. For an affine point $R = (x, y)$, the line through R and $O = [0 : 1 : 0]$ is the vertical line through x, and its third point is

$$-R = (x, -y - a_1 x - a_3).$$

Hence $P + Q = -R$, and $P + Q + R = O$ whenever P, Q, R are the three intersections of a line with E (the line at infinity $Z = 0$ meets E only at O, with multiplicity 3).

Proposition 9.11 (the addition formulas)**.** *Let $P_1 = (x_1, y_1)$ and $P_2 = (x_2, y_2)$ be affine points of E.*

(i) If $x_1 = x_2$ and $y_2 = -y_1 - a_1 x_1 - a_3$, then $P_1 + P_2 = O$.

(ii) Otherwise put, if $x_1 \neq x_2$,

$$\lambda = \frac{y_2 - y_1}{x_2 - x_1}, \qquad \nu = \frac{y_1 x_2 - y_2 x_1}{x_2 - x_1},$$

and, if $P_1 = P_2$ (so $2y_1 + a_1 x_1 + a_3 \neq 0$),

$$\lambda = \frac{3x_1^2 + 2a_2 x_1 + a_4 - a_1 y_1}{2y_1 + a_1 x_1 + a_3}, \qquad \nu = \frac{-x_1^3 + a_4 x_1 + 2a_6 - a_3 y_1}{2y_1 + a_1 x_1 + a_3}.$$

Then $P_1 + P_2 = (x_3, y_3)$ with $x_3 = \lambda^2 + a_1\lambda - a_2 - x_1 - x_2$ and $y_3 = -(\lambda + a_1)x_3 - \nu - a_3$.

(iii) (Duplication.) If $2P \neq O$, then with F as in Lemma 9.3,

$$x(2P) = \frac{x^4 - b_4 x^2 - 2b_6 x - b_8}{4x^3 + b_2 x^2 + 2b_4 x + b_6} \quad (x = x(P)).$$

(iv) The points $P \neq O$ with $2P = O$ are those with $2y + a_1 x + a_3 = 0$; when $\mathrm{char}\, K \neq 2$ their x-coordinates are the three distinct roots of $F(x) = 4x^3 + b_2 x^2 + 2b_4 x + b_6$, so $E[2]$ has four elements.

Proof. (i) $P_2 = -P_1$ by the formula for $-R$. (ii) The line $y = \lambda x + \nu$ passes through P_1 and P_2. For $x_1 \neq x_2$ this is the two-point form of a line: $\lambda x_1 + \nu = (y_2x_1 - y_1x_1 + y_1x_2 - y_2x_1)/(x_2 - x_1) = y_1$, and similarly at P_2. For $P_1 = P_2$, write $\eta_1 = 2y_1 + a_1x_1 + a_3$ and $\xi_1 = 3x_1^2 + 2a_2x_1 + a_4 - a_1y_1$; implicit differentiation of (9.1) gives $\eta\,dy = \xi\,dx$, so $\lambda = \xi_1/\eta_1$ is the slope of the tangent, and $\nu = y_1 - \lambda x_1 = (y_1\eta_1 - x_1\xi_1)/\eta_1$. Here $y_1\eta_1 - x_1\xi_1 = 2(y_1^2 + a_1x_1y_1) + a_3y_1 - 3x_1^3 - 2a_2x_1^2 - a_4x_1$, and replacing $y_1^2 + a_1x_1y_1$ by $x_1^3 + a_2x_1^2 + a_4x_1 + a_6 - a_3y_1$ (the equation of E at P_1) leaves $-x_1^3 + a_4x_1 + 2a_6 - a_3y_1$, the displayed numerator. Substituting $y = \lambda x + \nu$ into (9.1) gives a monic cubic in x,

$$x^3 + (a_2 - \lambda^2 - a_1\lambda)x^2 + \cdots = 0,$$

whose roots are x_1, x_2, x_3 (with multiplicity). Comparing the x^2-coefficients gives $x_1 + x_2 + x_3 = \lambda^2 + a_1\lambda - a_2$. The third point is $R = (x_3, \lambda x_3 + \nu)$, and $P_1 + P_2 = -R$. (iii) Substitute the tangent slope into $x_3 = \lambda^2 + a_1\lambda - a_2 - 2x_1$. When $\operatorname{char} K \neq 2$ the computation is short. Write $x = x_1$, $\eta = \eta_1$, $\xi = \xi_1$; then $\lambda^2 + a_1\lambda = (\lambda + \frac{a_1}{2})^2 - \frac{a_1^2}{4}$ and

$$\eta\Big(\lambda + \frac{a_1}{2}\Big) = \xi + \frac{a_1}{2}\eta = 3x^2 + \Big(2a_2 + \frac{a_1^2}{2}\Big)x + a_4 + \frac{a_1a_3}{2} = \frac{1}{4}F'(x),$$

the term a_1y cancelling. With $\eta^2 = F(x)$ (Lemma 9.3(ii)) and $a_1^2/4 + a_2 = b_2/4$,

$$x(2P) = \frac{F'(x)^2}{16F(x)} - \frac{b_2}{4} - 2x = \frac{F'(x)^2 - 4(b_2 + 8x)F(x)}{16F(x)}.$$

Expanding, $F'(x)^2 = 144x^4 + 48b_2x^3 + (4b_2^2 + 48b_4)x^2 + 8b_2b_4x + 4b_4^2$ and $4(b_2 + 8x)F(x) = 128x^4 + 48b_2x^3 + (4b_2^2 + 64b_4)x^2 + (8b_2b_4 + 32b_6)x + 4b_2b_6$; the difference is $16x^4 - 16b_4x^2 - 32b_6x - 4(b_2b_6 - b_4^2) = 16(x^4 - b_4x^2 - 2b_6x - b_8)$, by Lemma 9.3(i). In characteristic 2 the same formula holds: the statement says $\xi^2 + a_1\xi\eta - (a_2 + 2x)\eta^2 = x^4 - b_4x^2 - 2b_6x - b_8$ in $\mathbb{Z}[a_1, \ldots, a_6][x, y]$ modulo the equation of E, a ring that is free with basis $1, y$ over $\mathbb{Z}[a_1, \ldots, a_6][x]$; the computation just made proves it after tensoring with $\mathbb{Q}$, hence over $\mathbb{Z}$ (a free module over a torsion-free ring has no torsion), hence after any specialisation (it was also checked by machine). On `11a1` at $P = (5, 5)$ it gives $x(2P) = 1936/121 = 16$. (iv) $2P = O$ means $P = -P$, i.e. $y = -y - a_1x - a_3$. In characteristic not 2 this is $\eta = 0$, so $F(x) = 0$ by Lemma 9.3(ii); conversely each root of F gives exactly one point with $\eta = 0$. The roots are distinct because $\operatorname{disc} F = 16\Delta \neq 0$. □

Proposition 9.12 (the chord-tangent law is the law of Pic^0)**.** *Let $\kappa\colon E(\bar{K}) \to \mathrm{Pic}^0(E)$, $P \mapsto$ the class of $(P) - (O)$, be the bijection of Chapter 8. Then $\kappa(P + Q) = \kappa(P) + \kappa(Q)$ for the chord-tangent law of Construction 9.10.*

Proof. Let P, Q be given, R the third point of the line L through them, and $P + Q = -R$ the third point of the line L' through R and O. Write L and L' as linear forms in X, Y, Z. The rational functions L/Z and L'/Z have divisors

$$\operatorname{div}(L/Z) = (P)+(Q)+(R)-3(O), \qquad \operatorname{div}(L'/Z) = (R)+(-R)+(O)-3(O) = (R)+(-R)-2(O),$$

because L meets E in P, Q, R, and Z meets E only at O with multiplicity 3 (if L or L' is the line $Z = 0$ itself the corresponding statement is trivial). Hence $\operatorname{div}(L/L') = (P)+(Q)-(P+Q)-(O)$, so $(P) - (O) + (Q) - (O) \sim (P + Q) - (O)$, which is the claim. □

Theorem 9.13 (the group law)**.**

(i) $(E(\bar K),+)$ *is an abelian group with identity* O *and inverse* $P\mapsto -P$.

(ii) For every field L *with* $K\subseteq L\subseteq \bar K$, $E(L)$ *is a subgroup, and* $\sigma(P+Q)=\sigma P+\sigma Q$ *for every automorphism* σ *of* $\bar K$ *over* K.

(iii) The maps $E\times E\to E$, $(P,Q)\mapsto P+Q$, *and* $E\to E$, $P\mapsto -P$, *are morphisms (given by rational functions with coefficients in* K*); in particular each translation* $\tau_Q\colon P\mapsto P+Q$ *is an isomorphism of curves, defined over* K *if* $Q\in E(K)$.

Proof. (i) Commutativity is built into the construction (the line through P and Q is the line through Q and P); $P+O=P$ because the line through P and O meets E again at $-P$, and the line through $-P$ and O meets it at P; and $P+(-P)=O$ because the vertical line through P meets E in P, $-P$, O, and the tangent at O is $Z=0$, which meets E only at O. Associativity holds because κ is a bijection onto the group $\mathrm{Pic}^0(E)$ that carries $+$ to the group law there (Proposition 9.12). A direct verification from the formulas is possible but long; see [185, Section III.2] and the references there. (ii) The formulas of Proposition 9.11 have coefficients in K, so they commute with σ and preserve coordinates in L. (iii) The formulas of Proposition 9.11 are rational functions; that they define a morphism also at the excluded points (where $x_1=x_2$, or a point is O) is [185, Section III.3]; for τ_Q with Q fixed it follows from Chapter 8 (a rational map from a smooth curve to a projective variety is a morphism), and τ_{-Q} is its inverse. □

Corollary 9.14 (principal divisors)**.** *A divisor* $D=\sum n_P(P)$ *on* E *is principal if and only if* $\deg D=0$ *and* $\sum[n_P]P=O$ *in* $E(\bar K)$.

Proof. For $\deg D=0$, $D=\sum n_P\big((P)-(O)\big)$ has class $\sum n_P\kappa(P)=\kappa\big(\sum[n_P]P\big)$ by Proposition 9.12. Since κ is injective, the class is 0 iff $\sum[n_P]P=O$. Principal divisors have degree 0 (Chapter 8). □

Proposition 9.15 (the invariant differential)**.** *Let* ω *be the invariant differential of* E.

(i) ω *is holomorphic and has no zeros:* $\operatorname{div}(\omega)=0$.

(ii) $\tau_Q^*\omega=\omega$ *for every* $Q\in E(\bar K)$.

(iii) Let E' *be an elliptic curve and* $\varphi,\psi\colon E'\to E$ *morphisms with* $\varphi(O)=\psi(O)=O$ *(isogenies, Definition 9.17). Then* $(\varphi+\psi)^*\omega=\varphi^*\omega+\psi^*\omega$, *where* $\varphi+\psi$ *is the pointwise sum and the pullback by the zero map is* 0. *Hence* $[m]^*\omega=m\,\omega$ *for every* $m\in\mathbb{Z}$.

Proof. (i) is Chapter 8 (the divisor of $dx/(2y+a_1x+a_3)$ on a smooth Weierstrass cubic). For (ii) and (iii) put $\eta=2y+a_1x+a_3$ and $\xi=3x^2+2a_2x+a_4-a_1y$. Differentiating (9.1) gives $\eta\,dy=\xi\,dx$, and $\omega=dx/\eta$. For a morphism φ from a smooth curve to E we put $\varphi^*\omega=0$ if φ is constant; if φ is nonconstant, $\varphi^*\eta\neq 0$ (pullback is injective on function fields) and $\varphi^*\omega=d(\varphi^*x)/\varphi^*\eta$.

Step 1 (an identity). Let x_1,y_1,x_2,y_2 be indeterminates, $W(x,y)=y^2+a_1xy+a_3y-x^3-a_2x^2-a_4x-a_6$, and let X_3, Y_3 be the expressions for x_3, y_3 in the chord case of Proposition 9.11(ii), so that their denominators are powers of x_2-x_1. Put $H_3=2Y_3+a_1X_3+a_3$, and η_i, ξ_i for η, ξ evaluated at (x_i,y_i). Then for $i=1,2$

$$\eta_i\,\frac{\partial X_3}{\partial x_i}+\xi_i\,\frac{\partial X_3}{\partial y_i}=H_3 \tag{9.2}$$

in the ring $\mathbb{Z}[a_1,a_2,a_3,a_4,a_6][x_1,y_1,x_2,y_2,(x_1-x_2)^{-1}]$ modulo the ideal generated by $W(x_1,y_1)$ and $W(x_2,y_2)$. Since W is monic of degree 2 in y, the difference of the two sides can be reduced, by subtracting multiples of $W(x_1,y_1)$ and $W(x_2,y_2)$, to an expression of degree at most 1 in y_1 and in y_2, without new denominators. We carried out this reduction with PARI/GP, with $a_1,\dots,a_6$ indeterminate, and it gives 0. So (9.2) holds after any specialisation of the variables into a field in which $W(x_1,y_1)=W(x_2,y_2)=0$ and $x_1\neq x_2$, in every characteristic.

Step 2 (sums of morphisms). Let C be a smooth curve over $\bar{K}$ and $\varphi,\psi\colon C\to E$ morphisms, neither of them the constant map to O, such that $x\circ\varphi\neq x\circ\psi$ and the pointwise sum $\varphi+\psi$ is a nonconstant morphism. We show $(\varphi+\psi)^*\omega=\varphi^*\omega+\psi^*\omega$. Put $x_1=\varphi^*x$, $y_1=\varphi^*y$, $x_2=\psi^*x$, $y_2=\psi^*y$ in $\bar{K}(C)$; then $W(x_i,y_i)=0$ and $x_1-x_2\neq 0$. The sets $\varphi^{-1}(O)$ and $\psi^{-1}(O)$ are finite, and x_1-x_2 has finitely many zeros, so at all but finitely many $P\in C$ the points $\varphi(P)$, $\psi(P)$ are affine with different x-coordinates, and there Proposition 9.11(ii) gives $(\varphi+\psi)(P)=(X_3,Y_3)\big(x_1(P),y_1(P),x_2(P),y_2(P)\big)$. Two rational functions on C that agree at infinitely many points are equal, so $(\varphi+\psi)^*x=X_3(x_1,y_1,x_2,y_2)$ and $(\varphi+\psi)^*\eta=H_3(x_1,y_1,x_2,y_2)$, the latter nonzero because $\varphi+\psi$ is nonconstant. By the chain rule for the derivation d of $\bar{K}(C)$,

$$d\big((\varphi+\psi)^*x\big)=\sum_{i=1,2}\Big(\frac{\partial X_3}{\partial x_i}\,dx_i+\frac{\partial X_3}{\partial y_i}\,dy_i\Big).$$

If φ is nonconstant, $\eta_1=\varphi^*\eta\neq 0$ and pulling back $\eta\,dy=\xi\,dx$ gives $dy_1=(\xi_1/\eta_1)\,dx_1$; so the term $i=1$ is $(\eta_1\partial X_3/\partial x_1+\xi_1\partial X_3/\partial y_1)dx_1/\eta_1=H_3\,\varphi^*\omega$ by (9.2). If φ is constant, $dx_1=dy_1=0$ and the term is $0=H_3\,\varphi^*\omega$. The same holds for $i=2$. Dividing by $H_3=(\varphi+\psi)^*\eta$ gives the claim.

(ii) For $Q=O$ there is nothing to prove. For $Q\neq O$ apply Step 2 with $C=E$, φ the identity and ψ the constant map to Q: then $\varphi+\psi=\tau_Q$ is an isomorphism (Theorem 9.13(iii)) and $x\neq x(Q)$, so $\tau_Q^*\omega=\omega+0=\omega$.

(iii) First, $x\circ[-1]=x$ and $y\circ[-1]=-y-a_1x-a_3$ (Construction 9.10), so $[-1]^*\eta=-\eta$ and $[-1]^*\omega=-\omega$. The maps $\varphi\pm\psi$ are morphisms sending O to O (Theorem 9.13(iii)), and such a morphism is either the zero map or nonconstant, in which case its fibres, in particular its kernel, are finite (Chapter 8). If $\varphi=0$ or $\psi=0$ there is nothing to prove. If $\psi=-\varphi$, then $(\varphi+\psi)^*\omega=0$ and $\psi^*\omega=\varphi^*[-1]^*\omega=-\varphi^*\omega$. If $\psi=\varphi$: the set $E[2]$ is finite, since its points other than O are the zeros of the nonzero function η (Proposition 9.11(iv)); choose Q with $2Q\neq O$. Then $\tau_Q+\tau_{-Q}=[2]$ is nonconstant, and $x\circ\tau_Q\neq x\circ\tau_{-Q}$: otherwise for every P the points $P+Q$ and $P-Q$ would be equal or opposite, so $2Q=O$ or $2P=O$, and $E(\bar{K})=E[2]$ would be finite. Step 2 and (ii) give $[2]^*\omega=\tau_Q^*\omega+\tau_{-Q}^*\omega=2\omega$, hence $(2\varphi)^*\omega=([2]\circ\varphi)^*\omega=\varphi^*[2]^*\omega=2\varphi^*\omega$. In the remaining case $\varphi,\psi\neq 0$ and $\psi\neq\pm\varphi$, so $\varphi+\psi$ is nonconstant; and $x\circ\varphi\neq x\circ\psi$, for otherwise $\varphi(P)=\pm\psi(P)$ for every P (two points with the same x-coordinate in $\mathbb{P}^1$ are equal or opposite), and $E'(\bar{K})$, which is infinite, would be the union of the finite kernels of $\varphi-\psi$ and $\varphi+\psi$. Step 2 applies.

Finally $[0]^*\omega=0$, $[m+1]^*\omega=[m]^*\omega+\omega$ for $m\geq 0$ by what was just proved, so $[m]^*\omega=m\,\omega$ for $m\geq 0$, and $[-m]^*\omega=([-1]\circ[m])^*\omega=[m]^*(-\omega)=-m\,\omega$. Silverman [185, Section III.5] argues differently, proving (iii) through differentials on $E\times E$; the explicit identity of Step 1 replaces that argument here. □

Example 9.16 (torsion points on the running examples)**.** All computed with Proposition 9.11 (and checked with PARI).

(a) On `11a1`, $P=(5,5)$: $2P=(16,-61)$, $3P=(16,60)$, $4P=(5,-6)$, $5P=O$. Indeed $3P=-2P$ because $-(16,-61)=(16,61-1)=(16,60)$. In detail, with $a_1=0$, $a_2=-1$,

$a_3 = 1$, $a_4 = -10$: the tangent at P has $\lambda = (3 \cdot 25 - 10 - 10)/(10 + 1) = 5$ and $\nu = 5 - 25 = -20$, so $x(2P) = 25 + 0 + 1 - 10 = 16$ and $y(2P) = -5 \cdot 16 + 20 - 1 = -61$. The chord through P and $2P$ has $\lambda = (-61 - 5)/(16 - 5) = -6$ and $\nu = (5 \cdot 16 + 61 \cdot 5)/11 = 35$, so $x(3P) = 36 + 1 - 5 - 16 = 16$ and $y(3P) = 6 \cdot 16 - 35 - 1 = 60$. Since $x(3P) = x(2P)$ and $3P \neq 2P$, $3P = -2P$, so $5P = O$; and $4P = -P = (5, -5 - 1)$.

(b) On `20a1` $= [0, 1, 0, 4, 4]$, that is $y^2 = (x+1)(x^2+4)$: $(-1, 0)$ has order 2 (it satisfies $2y = 0$), $(0, 2)$ has order 3, and $(4, 10)$ has order 6, with $2(4, 10) = (0, 2)$ and $3(4, 10) = (-1, 0)$. For the doubling, $\lambda = (48 + 8 + 4)/20 = 3$, $\nu = 10 - 12 = -2$, $x = 9 - 1 - 8 = 0$ and $y = 2$. For $(4, 10) + (0, 2)$, $\lambda = 8/4 = 2$, $\nu = (0 - 8)/(-4) = 2$, $x = 4 - 1 - 4 - 0 = -1$ and $y = 2 - 2 = 0$.

(c) On `14a1` $= [1, 0, 1, 4, -6]$: $(2, -5)$ has order 3 (with $2(2, -5) = (2, 2) = -(2, -5)$), and $(9, 23)$ has order 6, with $2(9, 23) = (2, 2)$, $3(9, 23) = (1, -1)$.

(d) On `27a1` $= [0, 0, 1, 0, -7]$: $(3, 4)$ has order 3, $2(3, 4) = (3, -5)$.

(e) On `99a1`, $(0, 0)$ has infinite order: its multiples $(3, 2)$, $(-8/9, 13/27)$, $(105/64, -897/512)$ have growing denominators, which torsion points cannot have (Proposition 9.71); its canonical height is $0.3025\ldots > 0$.

The group law makes the maps $[m]$ and, more generally, maps of curves preserving O into the natural morphisms between elliptic curves. Two facts from this section drive the next one: $E(\bar{K}) \to \mathrm{Pic}^0(E)$ is a group isomorphism (so kernels and pullbacks of divisors can be computed with Corollary 9.14), and $[m]^*\omega = m\omega$ (so $[m]$ is separable when $\mathrm{char}\, K \nmid m$, and $E[m]$ can be counted).

9.3 Isogenies

The paper works with isogeny classes: the $X_0(N)$-optimal curve is one curve of a class, a rational ℓ-isogeny is the Eisenstein case of Conjecture conj:eis, and Proposition prop:no9 is an argument about a cyclic isogeny of degree 27. This section defines isogenies and their degree, states the existence of quotients by finite subgroups and of the dual isogeny, and proves the consequences the book needs: $\deg[m] = m^2$, $E[m] \simeq (\mathbb{Z}/m)^2$ when $\mathrm{char}\, K \nmid m$, and the factorisation of an isogeny into a multiplication map and a cyclic isogeny.

Definition 9.17 (isogenies)**.** Let E_1, E_2 be elliptic curves over K. An *isogeny* $\varphi\colon E_1 \to E_2$ is a morphism of curves with $\varphi(O) = O$. It is *defined over* K if it is given by rational functions with coefficients in K; for perfect K this holds iff $\varphi(\sigma P) = \sigma\varphi(P)$ for all $\sigma \in G_K$ and $P \in E_1(\bar{K})$ (Chapter 8). Its *degree* is $\deg\varphi = [\bar{K}(E_1) : \varphi^*\bar{K}(E_2)]$ if φ is nonconstant and $\deg 0 = 0$; $\deg_s\varphi$ and $\deg_i\varphi$ are the separable and inseparable degrees, and φ is *separable* if $\deg_i\varphi = 1$ (Chapter 8). $\mathrm{Hom}(E_1, E_2)$ is the set of isogenies (over $\bar{K}$ unless stated otherwise), $\mathrm{End}(E) = \mathrm{Hom}(E, E)$, and $[m]\colon E \to E$ is multiplication by $m \in \mathbb{Z}$. E_1 and E_2 are *isogenous over* K if there is a nonconstant isogeny $E_1 \to E_2$ defined over K. For $m \geq 1$, $E[m] = \{P \in E(\bar{K}) : mP = O\}$.

Proposition 9.18 (first properties)**.**

(i) An isogeny is either constant (the zero map) or surjective on $\bar{K}$-points.

(ii) $\mathrm{Hom}(E_1, E_2)$ *is an abelian group under* $(\varphi+\psi)(P) = \varphi(P)+\psi(P)$, $\mathrm{End}(E)$ *is a ring under composition, and* $\deg(\psi\circ\varphi) = \deg\psi\cdot\deg\varphi$.

(iii) *For* $m \neq 0$, $[m] \neq 0$. *Hence* $\mathrm{Hom}(E_1, E_2)$ *is torsion-free, and* $\mathrm{End}(E)$ *has characteristic* 0.

Proof. (i) is Chapter 8 (a morphism of curves is constant or surjective). (ii) $\varphi+\psi$ is the composite of $(\varphi,\psi)\colon E_1 \to E_2 \times E_2$ with the addition morphism (Theorem 9.13(iii)), hence a morphism, and it sends O to O. The group and ring axioms hold pointwise. For nonconstant φ, ψ the degree is multiplicative in the tower $\bar{K}(E_1) \supseteq \varphi^*\bar{K}(E_2) \supseteq \varphi^*\psi^*\bar{K}(E_3)$; if one of them is constant both sides are 0. (iii) Assume first $\mathrm{char}\, K \neq 2$ and write $m = \pm 2^a m'$ with m' odd; as degrees multiply, it suffices to show $[2] \neq 0$ and $[m'] \neq 0$. By Proposition 9.11(iv) the points with $2P = O$ are O and three points with $2y + a_1x + a_3 = 0$; since $E(\bar{K})$ is infinite, $[2] \neq 0$. Let T be one of the three points of order 2 (a root of the cubic F). Then $m'T = T \neq O$, so $[m'] \neq 0$. In characteristic 2 the same argument works with [3] in place of [2] and a point of order 3 in place of T (the x-coordinates of the points of order 3 are roots of ψ_3, of degree 4 in characteristic 2; Proposition 9.29(i)); see [185, Section III.4] for the details. Finally, if $n\varphi = 0$ with $n \neq 0$, then $[n]\circ\varphi = 0$; a nonzero φ is surjective by (i), so $[n]$ would vanish on $E_2(\bar{K})$, which we have excluded. Hence $\varphi = 0$. □

Theorem 9.19 (isogenies are homomorphisms; kernels)**.** *Let* $\varphi\colon E_1 \to E_2$ *be a nonconstant isogeny.*

(i) $\varphi(P+Q) = \varphi(P)+\varphi(Q)$ *for all* P, Q.

(ii) $\ker\varphi$ *is finite of order* $\deg_s\varphi$. *Every fibre* $\varphi^{-1}(Q)$ *has* $\deg_s\varphi$ *points, each with ramification index* $\deg_i\varphi$.

(iii) *If* φ *is separable, then* $\#\ker\varphi = \deg\varphi$, φ *is unramified, and* $\bar{K}(E_1)/\varphi^*\bar{K}(E_2)$ *is a Galois extension whose group is* $\{\tau_T^* : T \in \ker\varphi\} \simeq \ker\varphi$.

Sketch of proof. (i) The pushforward φ_* on divisors maps principal divisors to principal divisors (Chapter 8), so it induces a homomorphism $\mathrm{Pic}^0(E_1) \to \mathrm{Pic}^0(E_2)$, and $\varphi_*((P)-(O)) = (\varphi P)-(O)$. Through the bijections κ of Proposition 9.12 this says that φ is a homomorphism. (ii) For $T \in \ker\varphi$, $\varphi\circ\tau_T = \varphi$ by (i), so τ_T permutes each fibre and preserves ramification indices: $e_\varphi(P+T) = e_\varphi(P)$. Hence all points of a fibre $\varphi^{-1}(Q) = P + \ker\varphi$ have the same index e, and the degree formula of Chapter 8 gives $\#\ker\varphi\cdot e = \deg\varphi$. Since all but finitely many fibres have exactly $\deg_s\varphi$ points (Chapter 8), $\#\ker\varphi = \deg_s\varphi$ and $e = \deg_i\varphi$. (iii) If φ is separable, $e = 1$ everywhere and $\#\ker\varphi = \deg\varphi$. The $\deg\varphi$ automorphisms τ_T^*, $T \in \ker\varphi$, of $\bar{K}(E_1)$ fix $\varphi^*\bar{K}(E_2)$ (as $\varphi\circ\tau_T = \varphi$) and are distinct; an extension of degree n with n automorphisms over the base is Galois with that group (Chapter 5). This is [185, Section III.4]. In characteristic 0 every morphism of genus-one curves is separable and unramified (Chapter 8, Riemann-Hurwitz), which gives (iii) directly. □

Theorem 9.20 (quotients by finite subgroups)**.**

(i) *Let* $H \subset E(\bar{K})$ *be a finite subgroup. There are an elliptic curve* E' *and a separable isogeny* $\varphi\colon E \to E'$ *with* $\ker\varphi = H$; *the pair is unique up to a unique isomorphism of* E'. *If* H *is stable as a set under* G_K, *then* E' *and* φ *can be taken to be defined over* K. *We write* $E' = E/H$.

(ii) (Factorisation.) Let $\varphi\colon E \to E_1$ and $\psi\colon E \to E_2$ be nonconstant isogenies with ψ separable and $\ker\psi \subseteq \ker\varphi$. Then there is a unique isogeny $\lambda\colon E_2 \to E_1$ with $\varphi = \lambda\circ\psi$; if φ and ψ are defined over K, so is λ, and $\ker\lambda = \psi(\ker\varphi)$.

We do not prove this; see [185, Section III.4 and Exercise 3.13]. The idea of (ii): by Theorem 9.19(iii), $\varphi^*\bar{K}(E_1)$ is fixed by the translations by $\ker\psi$, hence contained in $\psi^*\bar{K}(E_2)$, and an inclusion of function fields is a morphism (Chapter 8); λ is unique because ψ is surjective, and $\lambda^\sigma\circ\psi = \varphi^\sigma = \varphi$ gives $\lambda^\sigma = \lambda$. The quotient in (i) is the curve whose function field is the fixed field of the translations by H. Vélu's formulas [200] give an explicit Weierstrass equation for E/H and for φ in terms of the coordinates of the points of H (PARI's `ellisogeny`).

Theorem 9.21 (the dual isogeny)**.** *Let $\varphi\colon E_1 \to E_2$ be a nonconstant isogeny of degree m. There is a unique isogeny $\hat\varphi\colon E_2 \to E_1$ with $\hat\varphi\circ\varphi = [m]_{E_1}$. Moreover:*

(i) $\varphi\circ\hat\varphi = [m]_{E_2}$, $\deg\hat\varphi = \deg\varphi$ and $\hat{\hat\varphi} = \varphi$;

(ii) $\widehat{\psi\circ\varphi} = \hat\varphi\circ\hat\psi$, $\widehat{\varphi+\psi} = \hat\varphi + \hat\psi$ (with $\hat 0 = 0$), and $\widehat{[m]} = [m]$;

(iii) if φ is defined over K, so is $\hat\varphi$;

(iv) $\deg\colon \mathrm{Hom}(E_1,E_2) \to \mathbb{Z}$ is a positive definite quadratic form: $\deg(n\varphi) = n^2\deg\varphi$, $\deg\varphi \geq 0$ with equality only for $\varphi = 0$, and $\langle\varphi,\psi\rangle = \deg(\varphi+\psi) - \deg\varphi - \deg\psi$ is bilinear.

Sketch of proof. $\hat\varphi$ is the composite $E_2 \xrightarrow{\kappa} \mathrm{Pic}^0(E_2) \xrightarrow{\varphi^*} \mathrm{Pic}^0(E_1) \xrightarrow{\kappa^{-1}} E_1$: since $\varphi^*((Q)) = \sum_{\varphi(P)=Q} e_\varphi(P)(P)$ and all points of a fibre $P + \ker\varphi$ have index $\deg_i\varphi$ (Theorem 9.19(ii)), $\varphi^*((\varphi P) - (O)) = \deg_i\varphi\sum_{T\in\ker\varphi}((P+T)-(T))$, whose image under κ^{-1} is $[\deg_i\varphi\cdot\#\ker\varphi]P = [\deg\varphi]P$ by Corollary 9.14. Uniqueness: if $\psi\circ\varphi = \psi'\circ\varphi$ then $(\psi-\psi')\circ\varphi = 0$ and $\psi = \psi'$ as φ is surjective. The additivity $\widehat{\varphi+\psi} = \hat\varphi + \hat\psi$ is the deepest property; see [185, Section III.6]. The rest follows formally: from $\varphi\circ\hat\varphi\circ\varphi = \varphi\circ[m] = [m]\circ\varphi$ and surjectivity of φ one gets $\varphi\circ\hat\varphi = [m]$; then $\deg\varphi\deg\hat\varphi = \deg[m] = m^2$ (Corollary 9.22(i), whose proof uses only $\widehat{[m]} = [m]$, itself a consequence of additivity and $[\hat 1] = [1]$), so $\deg\hat\varphi = m$. For (iv), $[\deg(\varphi+\psi)] = (\widehat{\varphi+\psi})\circ(\varphi+\psi) = [\deg\varphi] + [\deg\psi] + \hat\psi\circ\varphi + \hat\varphi\circ\psi$, so $\langle\varphi,\psi\rangle$ corresponds to $\hat\psi\circ\varphi + \hat\varphi\circ\psi$, which is visibly biadditive; and $\mathrm{End}(E_1)$ is torsion-free (Proposition 9.18(iii)), so the identification of integers with multiplication maps is injective ($[a] = [b]$ forces $a = b$). The remaining parts of (iv) are elementary: $\deg(n\varphi) = \deg([n]\circ\varphi) = \deg[n]\deg\varphi = n^2\deg\varphi$ by multiplicativity and $\deg[n] = n^2$; and $\deg\varphi$ is a degree of a field extension, hence positive, for $\varphi \neq 0$, while $\deg 0 = 0$ by definition. A function $Q\colon A \to \mathbb{Z}$ on an abelian group with $Q(nx) = n^2Q(x)$ and $Q(x+y) - Q(x) - Q(y)$ biadditive is exactly a quadratic form. □

Corollary 9.22 (multiplication by m and the m-torsion)**.** *Let $m \geq 1$.*

(i) $\deg[m] = m^2$.

(ii) If $\mathrm{char}\,K \nmid m$, then $[m]$ is separable and $E[m] \simeq \mathbb{Z}/m \times \mathbb{Z}/m$.

(iii) If $\mathrm{char}\,K = p > 0$, then either $E[p^e] = 0$ for all $e \geq 1$, or $E[p^e] \simeq \mathbb{Z}/p^e$ for all $e \geq 1$.

Proof. (i) By Theorem 9.21, $\widehat{[m]} = [m]$ and $\widehat{[m]}\circ[m] = [\deg[m]]$, so $[m^2] = [\deg[m]]$ and $[m^2 - \deg[m]] = 0$; as $\mathrm{End}(E)$ is torsion-free (Proposition 9.18(iii)), $\deg[m] = m^2$. (ii) By Proposition 9.15(iii), $[m]^*\omega = m\omega \neq 0$, so $[m]$ is separable (Chapter 8: a morphism is separable iff

it pulls back a nonzero differential to a nonzero one). The same holds for every $d \mid m$, as $\operatorname{char} K \nmid d$; so by Theorem 9.19(iii) and (i), $\#E[d] = \#\ker[d] = \deg[d] = d^2$ for every $d \mid m$. Let $A = E[m]$; it is a finite abelian group killed by m. For each prime $p \mid m$, $A[p] = E[p]$ has p^2 elements. By the structure theorem (Chapter 1) the p-primary part of A is a product $\mathbb{Z}/p^{a_1} \times \cdots \times \mathbb{Z}/p^{a_k}$ with all $a_i \geq 1$, whose p-torsion $(\mathbb{Z}/p)^k$ has p^k elements; so $k = 2$, the p-primary part is $\mathbb{Z}/p^a \times \mathbb{Z}/p^b$, and $a, b \leq v_p(m)$ because m kills A. Since $\#A = m^2$, $a + b = 2v_p(m)$, so $a = b = v_p(m)$, and $A \simeq (\mathbb{Z}/m)^2$. (iii) We do not prove this; see [185, Section III.6]. Over $\mathbb{C}$, Proposition 9.55(ii) gives a second proof of (i) and (ii). □

Proposition 9.23 (cyclic factorisation)**.** *Let* $\operatorname{char} K = 0$ *and let* $\varphi\colon E \to E'$ *be a nonconstant isogeny.*

(i) $\ker\varphi \simeq \mathbb{Z}/a \times \mathbb{Z}/ab$ *for unique integers* $a, b \geq 1$*, and* a *is the largest integer with* $E[a] \subseteq \ker\varphi$*.*

(ii) $\varphi = \psi \circ [a]$ *for a unique isogeny* $\psi\colon E \to E'$*, and* $\ker\psi = a \cdot \ker\varphi \simeq \mathbb{Z}/b$ *is cyclic. If* φ *is defined over* K*, so is* ψ*.*

(iii) An isogeny over K *with cyclic kernel of order* n *is called a* cyclic n-isogeny*. Its kernel* C *contains exactly one subgroup* C_d *of each order* $d \mid n$*, and* C_d *is* G_K*-stable. Consequently a cyclic* n*-isogeny over* K *is a composite of cyclic isogenies over* K *of prime degrees, and if* $\ell \mid n$ *then* E *has a* K*-rational cyclic* ℓ*-isogeny, with kernel* C_ℓ*.*

Proof. (i) $H = \ker\varphi$ is a finite subgroup of $E[N] \simeq (\mathbb{Z}/N)^2$ for $N = \#H$ (Corollary 9.22(ii)). For each prime p, $H[p] \subseteq E[p] \simeq (\mathbb{Z}/p)^2$, so the p-primary part of H has at most two cyclic factors, and $H \simeq \mathbb{Z}/d_1 \times \mathbb{Z}/d_2$ with $d_1 \mid d_2$ (invariant factors, Chapter 1); put $a = d_1$, $b = d_2/d_1$. Then $H[a] \simeq (\mathbb{Z}/a)^2$ has a^2 elements and lies in $E[a]$, which has a^2 elements, so $E[a] \subseteq H$; and if $E[a'] \subseteq H$ then $E[a'] \simeq (\mathbb{Z}/a')^2$ lies in $H[a'] \simeq \mathbb{Z}/\gcd(a', d_1) \times \mathbb{Z}/\gcd(a', d_2)$, a group of order at most $\gcd(a', d_1) \cdot a'$; comparing orders, $\gcd(a', d_1) = a'$, that is, $a' \mid d_1$. The integers a, b are unique because the invariant factors $d_1 \mid d_2$ are. (ii) $[a]$ is separable with kernel $E[a] \subseteq \ker\varphi$, so Theorem 9.20(ii) gives ψ with $\varphi = \psi \circ [a]$, unique, defined over K if φ is, and with kernel $[a](\ker\varphi) = a \cdot (\mathbb{Z}/a \times \mathbb{Z}/ab) \simeq \mathbb{Z}/b$. (iii) A cyclic group of order n has exactly one subgroup of each order $d \mid n$. For $\sigma \in G_K$, $\sigma(C_d)$ is a subgroup of order d of $\sigma(C) = C$, so $\sigma(C_d) = C_d$. For a prime $p \mid n$, the isogeny $E \to E/C_p$ is defined over K (Theorem 9.20(i)), and φ factors through it (Theorem 9.20(ii)) as $E \to E/C_p \to E'$, the second map having cyclic kernel C/C_p of order n/p, G_K-stable. Induction on n finishes the proof. □

Warning 9.24 (isogenous over which field). In the paper and in this book "isogenous" and "isogeny class" for curves over $\mathbb{Q}$ always mean over $\mathbb{Q}$. Two curves over $\mathbb{Q}$ can be isogenous over $\overline{\mathbb{Q}}$ without being isogenous over $\mathbb{Q}$: a curve and its quadratic twist by $\mathbb{Q}(\sqrt{d})$ are isomorphic over $\mathbb{Q}(\sqrt{d})$ (Definition 9.83), but in general not isogenous over $\mathbb{Q}$: `11a1` has $a_2 = -2$, while its twist `121d2` lies in the class of `121d1`, which has $a_2 = 2$ (Example 9.68), so the two are not isogenous over $\mathbb{Q}$ (Theorem 9.74(ii)).

The finite groups $E[m] \simeq (\mathbb{Z}/m)^2$ are now in place, but nothing so far says where their points lie. The next section writes down polynomials whose roots are the x-coordinates of the points of $E[m]$; for $m = 3$ this is the tool the paper uses to read off the mod 3 image.

9.4 Division polynomials

The paper decides whether the mod 3 image of E is the normaliser $N_s(\mathbb{F}_3)$ of a split Cartan subgroup by factoring the 3-division polynomial (Proposition prop:ns and the function `ns3` of its appendix, which calls `elldivpol(E,3)`). This section defines the division polynomials, proves their degrees, and proves that the four roots of ψ_3 are the x-coordinates of the four lines of $E[3]$, Galois-equivariantly. The group-theoretic side (which orbit patterns occur for which subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$) is in Chapters 1 and 5; the deduction of Proposition prop:ns is in Chapter 11.

Definition 9.25 (division polynomials)**.** Let $R = \mathbb{Z}[a_1, a_2, a_3, a_4, a_6]$, $F(x) = 4x^3 + b_2x^2 + 2b_4x + b_6 \in R[x]$, and let $A = R[x][\psi_2]/(\psi_2^2 - F(x))$, a free $R[x]$-module with basis $1, \psi_2$. Define $\psi_m \in A$ by

$$\psi_0 = 0, \quad \psi_1 = 1, \quad \psi_2 = \psi_2, \quad \psi_3 = 3x^4 + b_2x^3 + 3b_4x^2 + 3b_6x + b_8,$$
$$\psi_4 = \psi_2(2x^6 + b_2x^5 + 5b_4x^4 + 10b_6x^3 + 10b_8x^2 + (b_2b_8 - b_4b_6)x + b_4b_8 - b_6^2),$$

and recursively, for $m \geq 2$ and $m \geq 3$ respectively,

$$\psi_{2m+1} = \psi_{m+2}\psi_m^3 - \psi_{m-1}\psi_{m+1}^3, \qquad \psi_2\psi_{2m} = \psi_m(\psi_{m+2}\psi_{m-1}^2 - \psi_{m-2}\psi_{m+1}^2),$$

where the second formula defines ψ_{2m} because its right side is ψ_2 times an element of A (Proposition 9.26), and multiplication by ψ_2 is injective on A. On a curve E we evaluate ψ_m at the coefficients of E and put $\psi_2 = 2y + a_1x + a_3$, which satisfies $\psi_2^2 = F(x)$ on E (Lemma 9.3(ii)); so ψ_m becomes a function on E. These are the conventions of [185, Exercise 3.7] and of PARI; [202, Section 3.2] uses short models.

The idea behind the definition: $[m]$ is a morphism $E \to E$, so $x(mP)$ is a rational function of the coordinates of P, and its denominator should vanish exactly at the points with $mP = O$. The polynomials ψ_m are chosen to be these denominators (more precisely, $x(mP) = x - \psi_{m-1}\psi_{m+1}/\psi_m^2$, Theorem 9.27), and the recursions express ψ_{2m} and ψ_{2m+1} through the addition of mP and $(m+1)P$; the first cases are the duplication formula (ψ_2, ψ_3, Proposition 9.29(i)) and ψ_4. As an example, for `11a1` $= [0, -1, 1, -10, -20]$, with $b_2 = -4$, $b_4 = -20$, $b_6 = -79$, $b_8 = -21$ (Example 9.8), one gets $\psi_2^2 = F(x) = 4x^3 - 4x^2 - 40x - 79$ and $\psi_3 = 3x^4 - 4x^3 - 60x^2 - 237x - 21$, the polynomial listed in Example 9.30.

Proposition 9.26 (degrees)**.** *For odd $m \geq 1$, $\psi_m \in R[x]$ is a polynomial of degree $(m^2-1)/2$ with leading coefficient m. For even $m \geq 2$, $\psi_m = \psi_2 f_m$ with $f_m \in R[x]$ of degree $(m^2-4)/2$ and leading coefficient $m/2$.*

Proof. For $m \leq 4$ this is read off the definition ($f_2 = 1$; f_4 has degree 6 and leading coefficient 2). Assume it for all indices below the one considered; we use $\psi_2^2 = F$, of degree 3 with leading coefficient 4. Write ψ_k for odd k and $\psi_k = \psi_2 f_k$ for even k.

ψ_{2n+1}, $n \geq 2$. If n is even, $\psi_{n+2}\psi_n^3 = \psi_2^4 f_{n+2} f_n^3 = F^2 f_{n+2} f_n^3$ has degree $6 + \frac{(n+2)^2-4}{2} + 3\frac{n^2-4}{2} = 2n^2 + 2n$ and leading coefficient $16 \cdot \frac{n+2}{2} \cdot \frac{n^3}{8} = (n+2)n^3$, while $\psi_{n-1}\psi_{n+1}^3$ (odd indices) has degree $\frac{(n-1)^2-1}{2} + 3\frac{(n+1)^2-1}{2} = 2n^2 + 2n$ and leading coefficient $(n-1)(n+1)^3$. If n is odd the roles are exchanged: $\psi_{n+2}\psi_n^3$ has leading coefficient $(n+2)n^3$ and $\psi_{n-1}\psi_{n+1}^3 = F^2 f_{n-1} f_{n+1}^3$ has $16 \cdot \frac{n-1}{2} \cdot \frac{(n+1)^3}{8} = (n-1)(n+1)^3$, both of degree $2n^2 + 2n$. In both cases $\psi_{2n+1} \in R[x]$ has degree at most $2n^2 + 2n = \frac{(2n+1)^2-1}{2}$ and coefficient of that power

$$(n+2)n^3 - (n-1)(n+1)^3 = 2n + 1.$$

ψ_{2n}, $n \geq 3$. If n is odd, $\psi_{n\pm1}^2 = Ff_{n\pm1}^2$, so the bracket is $F(\psi_{n+2}f_{n-1}^2 - \psi_{n-2}f_{n+1}^2)$ and $\psi_{2n} = \psi_2 \cdot \psi_n(\psi_{n+2}f_{n-1}^2 - \psi_{n-2}f_{n+1}^2)$. The two products in the bracket have degree $\frac{(n\pm2)^2-1}{2} + (n \mp 1)^2 - 4 = \frac{3n^2-3}{2}$ and leading coefficients $(n+2)\frac{(n-1)^2}{4}$ and $(n-2)\frac{(n+1)^2}{4}$, whose difference is $\frac{1}{4}((n+2)(n-1)^2 - (n-2)(n+1)^2) = \frac{4}{4} = 1$. So f_{2n} has degree $\frac{n^2-1}{2} + \frac{3n^2-3}{2} = 2n^2 - 2 = \frac{(2n)^2-4}{2}$ and leading coefficient n. If n is even, $\psi_n = \psi_2 f_n$ and $\psi_{n\pm2} = \psi_2 f_{n\pm2}$, so $\psi_{2n} = \psi_2 \cdot f_n(f_{n+2}\psi_{n-1}^2 - f_{n-2}\psi_{n+1}^2)$; the bracket has degree $\frac{(n\pm2)^2-4}{2} + (n \mp 1)^2 - 1 = \frac{3n^2}{2}$ and leading coefficient $\frac{1}{2}((n+2)(n-1)^2 - (n-2)(n+1)^2) = 2$, so f_{2n} has degree $\frac{n^2-4}{2} + \frac{3n^2}{2} = 2n^2 - 2$ and leading coefficient $\frac{n}{2} \cdot 2 = n$. (For $n = 4$ the term $f_{n-2} = f_2 = 1$; the case $n - 2 = 0$ does not arise since $n \geq 3$.) In particular the right side of the even recursion is always ψ_2 times an element of $R[x]$, as Definition 9.25 requires. □

For `11a1` the degrees $0, 3, 4, 9, 12, 19, 24, 33, 40$ and leading coefficients $1, 4, 3, 8, 5, 12, 7, 16, 9$ of PARI's `elldivpol(E,m)`, $m = 1, \ldots, 9$, agree with Proposition 9.26: for even m PARI returns $\psi_2\psi_m = Ff_m$, of degree $3 + (m^2 - 4)/2$ and leading coefficient $4 \cdot m/2$.

Theorem 9.27 (multiplication by m)**.** *Let $m \geq 2$ with $\operatorname{char} K \nmid m$, and $P = (x, y) \in E(\bar{K})$. Then $mP = O$ if and only if $\psi_m(P) = 0$, and if $mP \neq O$,*

$$x(mP) = x - \frac{\psi_{m-1}\psi_{m+1}}{\psi_m^2}(P).$$

There is a similar formula for $y(mP)$ with denominator ψ_m^3. Equivalently,

$$\operatorname{div}(\psi_m) = \sum_{T \in E[m]} (T) - m^2(O).$$

Sketch of proof. The formulas are proved by induction on m from the addition formulas of Proposition 9.11, which is what the recursions of Definition 9.25 encode; see [202, Section 3.2] for short models and [185, Exercise 3.7] in general. For $m = 2$ the formula is the duplication formula, as $x - \psi_1\psi_3/\psi_2^2 = x - \psi_3/F = x(2P)$ by Proposition 9.29(i); for $m = 3$ the statement "$3P = O$ iff $\psi_3(P) = 0$" is Proposition 9.29(i). The form with divisors: ψ_m has poles only at O, of order $m^2 - 1$ (by Proposition 9.26, as $\operatorname{ord}_O x = -2$, $\operatorname{ord}_O y = -3$), and its zeros are the $m^2 - 1$ points of $E[m] \smallsetminus \{O\}$ (Corollary 9.22(ii)), each simple. □

Corollary 9.28 (roots of ψ_m for odd m)**.** *Let m be odd with $\operatorname{char} K \nmid m$. The roots of the polynomial $\psi_m(x)$ in $\bar{K}$ are exactly the x-coordinates of the points of $E[m] \smallsetminus \{O\}$; they are simple, there are $(m^2-1)/2$ of them, and $P \mapsto x(P)$ is a G_K-equivariant bijection $(E[m] \smallsetminus \{O\})/\{\pm1\} \to \{$roots of $\psi_m\}$.*

Proof. By Theorem 9.27 every $x(P)$, $P \in E[m] \smallsetminus \{O\}$, is a root. Two points have the same x-coordinate iff they are equal or opposite (the vertical line meets E in P, $-P$, O). No point of $E[m] \smallsetminus \{O\}$ has order 2 since m is odd, so $P \neq -P$, and the number of distinct values $x(P)$ is $(m^2 - 1)/2$ (Corollary 9.22(ii)). This is the degree of ψ_m, whose leading coefficient m is nonzero in K (Proposition 9.26); so these values are all the roots, each simple. Equivariance: ψ_m has coefficients in K and $x(\sigma P) = \sigma(x(P))$. □

Proposition 9.29 (the 3-division polynomial)**.** *Let $\psi_3 = 3x^4 + b_2x^3 + 3b_4x^2 + 3b_6x + b_8$.*

(i) As rational functions on E, $x(2P) - x(P) = -\psi_3(x)/\psi_2(P)^2$. Hence for $P \neq O$ with $2P \neq O$: $3P = O$ if and only if $\psi_3(x(P)) = 0$.

(ii) Let $\operatorname{char} K \neq 2,3$. *Then* $E[3]$ *is a two-dimensional* $\mathbb{F}_3$*-vector space with four lines* $\{O,P,-P\}$, *and* $\{O,P,-P\} \mapsto x(P)$ *is a* G_K*-equivariant bijection from the set of lines of* $E[3]$ *onto the set of the four (distinct) roots of* ψ_3. *Consequently the degrees of the irreducible factors of* ψ_3 *over* K *are the sizes of the orbits of* $\bar\rho_{E,3}(G_K)$ *on* $\mathbb{P}^1(\mathbb{F}_3)$ *(Definition 9.36);* ψ_3 *has a root in* K *iff* $E[3]$ *has a* G_K*-stable line, iff* E *has a* 3*-isogeny defined over* K *(Proposition 9.75).*

(iii) Let $K=\mathbb{Q}$. *Then* $\operatorname{disc}(\psi_3) \in -3\cdot(\mathbb{Q}^\times)^2$, *and the splitting field of* ψ_3 *contains* $\mathbb{Q}(\sqrt{-3})$.

Proof. (i) By the duplication formula (Proposition 9.11(iii)),

$$\begin{aligned} x(2P)-x &= \frac{x^4-b_4x^2-2b_6x-b_8-x(4x^3+b_2x^2+2b_4x+b_6)}{F(x)} \\ &= -\frac{3x^4+b_2x^3+3b_4x^2+3b_6x+b_8}{F(x)}, \end{aligned}$$

and $F(x)=\psi_2^2$ on E. If $P\neq O$ and $2P\neq O$, then $3P=O$ iff $2P=-P$ iff $x(2P)=x(P)$ (as $2P\neq P$), iff $\psi_3(x(P))=0$. (ii) $E[3]\simeq(\mathbb{Z}/3)^2$ by Corollary 9.22(ii); its lines are the four subgroups of order 3, each of the form $\{O,P,-P\}$. By Corollary 9.28 with $m=3$, x gives a G_K-equivariant bijection from the lines onto the four distinct roots of ψ_3. For a separable polynomial over K, the irreducible factors over K correspond to the G_K-orbits on its roots (Chapter 5); after a choice of basis, G_K acts on the lines of $E[3]$ through $\bar\rho_{E,3}$ and the action of $\mathrm{GL}_2(\mathbb{F}_3)$ on $\mathbb{P}^1(\mathbb{F}_3)$. A root in K is a fixed root, that is, a G_K-stable line. (iii) The roots $r_1,\dots,r_4$ are distinct, so $\delta=\prod_{i<j}(r_i-r_j)\neq 0$, $\operatorname{disc}\psi_3=3^6\delta^2$, and $\sigma(\delta)=\operatorname{sgn}(\pi_\sigma)\delta$ where π_σ is the permutation of the roots induced by $\sigma\in G_\mathbb{Q}$. (The factor $3^6=3^{2\cdot4-2}$ is the leading coefficient of ψ_3 to the power $2\deg-2$.) By (ii), π_σ is the permutation of the four lines of $E[3]$ induced by $\bar\rho_{E,3}(\sigma)$, whose sign is $\det\bar\rho_{E,3}(\sigma)\in\{\pm1\}=\mathbb{F}_3^\times$ (Chapter 1). To see this directly, note that $g\mapsto\operatorname{sgn}(\pi_g)$ and det are both homomorphisms $\mathrm{GL}_2(\mathbb{F}_3)\to\{\pm1\}$, so it suffices to compare them on generators. The group $\mathrm{SL}_2(\mathbb{F}_3)$ is generated by the transvections $\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}1&0\\1&1\end{smallmatrix}\right)$; the first fixes the line $[1:0]$ and permutes $[0:1]\mapsto[1:1]\mapsto[2:1]\mapsto[0:1]$ cyclically, an even permutation, and likewise for the second. And $\mathrm{GL}_2(\mathbb{F}_3)$ is generated by $\mathrm{SL}_2(\mathbb{F}_3)$ and $\operatorname{diag}(1,-1)$, which fixes $[1:0]$ and $[0:1]$ and swaps $[1:1]$ and $[1:-1]$, an odd permutation, with determinant -1. (A direct enumeration of the 48 elements confirms this.) Finally $\det\bar\rho_{E,3}=\bar\chi_3=\chi_{-3}$ (Corollary 9.33). So σ fixes δ iff σ fixes $\sqrt{-3}$; by Galois theory $\mathbb{Q}(\delta)=\mathbb{Q}(\sqrt{-3})$, and as the nontrivial automorphism of this field sends δ to $-\delta$, $\delta=b\sqrt{-3}$ with $b\in\mathbb{Q}^\times$, so $\delta^2=-3b^2\in-3(\mathbb{Q}^\times)^2$ and $\operatorname{disc}\psi_3=3^6\delta^2\in-3(\mathbb{Q}^\times)^2$. □

Example 9.30 (factorisations of ψ_3)**.** The following factorisations over $\mathbb{Q}$ and discriminants were computed with PARI (`elldivpol(E,3)`, `factor`, `poldisc`); the image of $\bar\rho_{E,3}$ is taken from Cremona's `galrep` file (labels of [191]; no label means surjective; their meaning is Chapter 11).

curve	ψ_3 over $\mathbb{Q}$	$\operatorname{disc}\psi_3$	image at 3
`11a1`	$3x^4-4x^3-60x^2-237x-21$ (irreducible)	$-3^3\cdot11^{10}$	$\mathrm{GL}_2(\mathbb{F}_3)$
`121a1`	$3x^4+5x^3-177x^2-909x-1249$ (irreducible)	$-3^3\cdot11^4$	$\mathrm{GL}_2(\mathbb{F}_3)$
`726a1`	$(x^2-x-74)(3x^2+8x+20)$	$-2^{12}3^911^6$	`3Ns`
`338d1`	$(x^2+29x+1858)(3x^2-82x-172)$	$-2^63^313^{18}$	`3Ns`
`6912d1`	$3(x^2-4x-2)(x^2+4x+6)$	$-2^{18}3^9$	`3Ns`
`20a1`	$x(3x^3+4x^2+24x+48)$	$-2^{16}3^35^4$	`3B.1.1`
`14a1`	$(x-2)(3x+1)(x^2+2x+13)$	$-2^{12}3^37^6$	`3Cs.1.1`
`27a1` (CM)	$3x(x-3)(x^2+3x+9)$	-3^{21}	`3Cs.1.1`
`121b1` (CM)	$(x^2+3x-6)(3x^2-13x+15)$	$-3^3\cdot11^6$	$N_s(\mathbb{F}_3)$, not listed

Every discriminant is -3 times a square, as Proposition 9.29(iii) says. For `726a1` the quadratic factors have discriminants $297 = 3^3 \cdot 11$ and $-176 = -2^4 \cdot 11$, so their roots generate $\mathbb{Q}(\sqrt{33})$ and $\mathbb{Q}(\sqrt{-11})$, and the third quadratic subfield of the compositum is $\mathbb{Q}(\sqrt{-3})$. For `20a1` the root $x = 0$ is the x-coordinate of the rational point $(0, 2)$ of order 3 (Example 9.16); the cubic factor is irreducible, so the other three lines form one orbit. For `14a1` the root 2 is the x-coordinate of $(2, -5)$, of order 3; the root $-1/3$ gives a second rational line, whose points $(-1/3, y)$ satisfy $y^2 + \frac{2}{3}y + \frac{199}{27} = 0$, of discriminant $-\frac{784}{27} = -3 \cdot (\frac{28}{9})^2$, so they are defined over $\mathbb{Q}(\sqrt{-3})$ and not over $\mathbb{Q}$: this line is μ_3 (Proposition 9.77). The curve `121b1` has complex multiplication by $\mathbb{Q}(\sqrt{-11})$, in which 3 splits. Its ψ_3 has no root in $\mathbb{Q}$, so $E[3]$ is irreducible (Proposition 9.29(ii)); the image has orbits of sizes $2, 2$ on $\mathbb{P}^1(\mathbb{F}_3)$ and contains the image of complex conjugation (determinant -1, trace 0), so by the classification recalled in Paper link 9.31 it is exactly $N_s(\mathbb{F}_3)$, the normaliser of the split Cartan subgroup attached to the two primes above 3 in $\mathbb{Q}(\sqrt{-11})$. The `galrep` file gives no label at 3 for this curve: for CM curves it often omits labels (it does give `3Cs.1.1` for the CM curves `27a1` and `27a3`).

In the paper 9.31. Proposition prop:ns says that, for $E[3]$ irreducible, the 3-division polynomial factors as a product of two irreducible quadratics when the image is $N_s(\mathbb{F}_3)$ and is irreducible otherwise. The bridge between the image and the polynomial is Proposition 9.29(ii): the orbits of $N_s(\mathbb{F}_3)$ on the four lines have sizes $2, 2$, and the other irreducible subgroups of $\mathrm{GL}_2(\mathbb{F}_3)$ containing an element of determinant -1 and trace 0 (complex conjugation, Corollary 9.39), namely the normaliser of a nonsplit Cartan subgroup and $\mathrm{GL}_2(\mathbb{F}_3)$ itself, act transitively (Chapter 1; the deduction is in Chapter 11). The paper's function `ns3` applies this to `elldivpol(E,3)`; a reducible $E[3]$ gives a linear factor. The CM curve `121b1` of the table has the pattern $2 + 2$ and image exactly $N_s(\mathbb{F}_3)$, consistently with Proposition prop:ns; the paper excludes CM curves from its data, and `ns3` would classify `121b1` correctly. Section sec:anomaly uses `726a1`. The proof of Proposition prop:ns itself is Chapter 11.

9.5 The Weil pairing, the Tate module and the Galois representations

Section 1.1 of the paper begins with $V = V_\ell E$, $T = T_\ell E$, $\rho = \rho_{E,\ell}$ and its reduction $\bar{\rho}$; every later statement is about these objects or about the adjoint $\mathrm{ad}^0 T$ built from them. This section constructs them, proves that $\det \rho_{E,\ell}$ is the cyclotomic character (through the Weil pairing), identifies $T_\ell E$ with its own dual twisted by $\mathbb{Z}_\ell(1)$, and fixes the Frobenius conventions. The paper uses these facts in Section 1.1, in Section 4.2 (the module T^D and the identification $M_{f,\lambda} = H^1(E, \mathbb{Z}_\ell)$ after Proposition prop:pullback), in Lemma lem:h0 (complex conjugation, $\det \rho = \chi_\ell$), and in Proposition prop:ns ($\det \bar{\rho}_{E,3} = \chi_{-3}$).

Theorem 9.32 (the Weil pairing)**.** *Let $m \geq 1$ with $\operatorname{char} K \nmid m$. There is a pairing $e_m \colon E[m] \times E[m] \to \mu_m$ with the following properties.*

(i) Bilinear: $e_m(S_1 + S_2, T) = e_m(S_1, T)e_m(S_2, T)$ and $e_m(S, T_1 + T_2) = e_m(S, T_1)e_m(S, T_2)$.

(ii) Alternating: $e_m(T, T) = 1$; hence $e_m(S, T) = e_m(T, S)^{-1}$.

(iii) Nondegenerate: if $e_m(S, T) = 1$ for all S, then $T = O$.

(iv) Galois-equivariant: $e_m(\sigma S, \sigma T) = \sigma(e_m(S, T))$ for $\sigma \in G_K$.

(v) Compatible: $e_{mm'}(S,T) = e_m(m'S,T)$ *for* $S \in E[mm']$ *and* $T \in E[m]$.

(vi) Adjoint: for an isogeny $\varphi\colon E \to E'$, $S \in E[m]$, $T \in E'[m]$: $e_m(S, \hat{\varphi}T) = e_m(\varphi S, T)$.

Sketch of proof. For $T \in E[m]$ there is $f \in \bar{K}(E)$ with $\operatorname{div}(f) = m(T) - m(O)$ (Corollary 9.14). Choose T' with $mT' = T$; there is g with $\operatorname{div}(g) = [m]^*(T) - [m]^*(O) = \sum_{R \in E[m]}\big((T'+R)-(R)\big)$, again by Corollary 9.14, since $\sum_R (T' + R - R) = [m^2]T' = O$. Then $f \circ [m]$ and g^m have the same divisor, so after scaling $f \circ [m] = g^m$. For $S \in E[m]$ and any point X, $g(X+S)^m = f(mX + mS) = f(mX) = g(X)^m$, so $g(X+S)/g(X)$ is an m-th root of unity; as a function of X it is a morphism $E \to \mathbb{P}^1$ that is not surjective, hence constant (Chapter 8). Define $e_m(S,T) = g(X+S)/g(X)$. Properties (i) to (vi) are proved in [185, Section III.8]; (iv) is immediate because σ carries the functions f, g for T to functions with the same properties for σT. Over $\mathbb{C}$, Proposition 9.55(iv) gives an explicit formula. □

The properties already determine e_2 completely when $\operatorname{char} K \neq 2$. Let $S \neq T$ be two points of order 2. By (iii) applied to T, together with (ii), some $S' \in E[2]$ has $e_2(S',T) = -1$; since $e_2(O,T) = e_2(T,T) = 1$, S' is one of the two points S, $S+T$, and $e_2(S+T,T) = e_2(S,T)e_2(T,T) = e_2(S,T)$, so $e_2(S,T) = -1$. Thus $e_2(S,T) = -1$ for any two distinct points of order 2, and $e_2 = 1$ whenever one argument is O or the two arguments are equal. For larger m the pairing carries genuine information; its first use is that it computes the determinant of the Galois action.

Corollary 9.33 (the determinant)**.** *Let* $m \geq 1$ *with* $\operatorname{char} K \nmid m$.

(i) For $\sigma \in G_K$ *acting on* $E[m]$ *by a matrix* $g_\sigma \in \mathrm{GL}_2(\mathbb{Z}/m)$ *in some basis,* $\det g_\sigma = \chi_m^{\mathrm{cyc}}(\sigma)$.

(ii) If $E[m] \subseteq E(K)$ *then* $\mu_m \subseteq K$.

(iii) Let ℓ *be prime and* $L \subset E[\ell]$ *a* G_K*-stable line. Then* $E[\ell]/L \simeq \operatorname{Hom}(L, \mu_\ell)$ *as* G_K*-modules. If* G_K *acts on* L *by* η_1 *and on* $E[\ell]/L$ *by* η_2*, then* $\eta_1\eta_2 = \bar{\chi}_\ell$. *In particular a* K*-rational point of order* ℓ *gives an exact sequence of* G_K*-modules* $0 \to \mathbb{Z}/\ell \to E[\ell] \to \mu_\ell \to 0$.

Proof. (i) Let S, T be the basis and $\zeta = e_m(S,T)$. It is a primitive m-th root of unity: if $\zeta^k = 1$ then $e_m(kS,T) = 1 = e_m(kS,S)$, so $e_m(kS,\cdot) = 1$ on $E[m]$ and $kS = O$ by (iii) and (ii) of Theorem 9.32, so $m \mid k$. If $\sigma S = aS + cT$ and $\sigma T = bS + dT$, bilinearity and the alternating property give $e_m(\sigma S, \sigma T) = e_m(S,T)^{ad} e_m(T,S)^{cb} = \zeta^{ad-bc}$, while Galois-equivariance gives $e_m(\sigma S, \sigma T) = \sigma(\zeta) = \zeta^{\chi_m^{\mathrm{cyc}}(\sigma)}$. So $\det g_\sigma \equiv \chi_m^{\mathrm{cyc}}(\sigma) \pmod m$. (ii) If G_K fixes $E[m]$ pointwise then $\chi_m^{\mathrm{cyc}}(\sigma) = \det 1 = 1$ for all σ, so G_K fixes μ_m. (iii) Consider $\theta\colon E[\ell] \to \operatorname{Hom}(L, \mu_\ell)$, $P \mapsto (Q \mapsto e_\ell(Q,P))$, a homomorphism by bilinearity. Its kernel is $L^\perp = \{P : e_\ell(L,P) = 1\}$, which contains L because $e_\ell(Q,Q') = 1$ for Q, Q' in the line L (write $Q' = kQ$ and use (i), (ii)). It is not all of $E[\ell]$: for a generator Q_0 of L, nondegeneracy and the alternating property give some P with $e_\ell(Q_0,P) = e_\ell(P,Q_0)^{-1} \neq 1$. So $L^\perp$ is a proper subspace containing the line L, hence $\ker\theta = L$, and θ is onto because both $E[\ell]/L$ and $\operatorname{Hom}(L,\mu_\ell)$ have ℓ elements. With the action $(\sigma h)(Q) = \sigma(h(\sigma^{-1}Q))$ on $\operatorname{Hom}(L,\mu_\ell)$, $(\sigma\theta(P))(Q) = \sigma e_\ell(\sigma^{-1}Q, P) = e_\ell(Q, \sigma P)$, so θ is G_K-equivariant. For $h \in \operatorname{Hom}(L,\mu_\ell)$ and $Q \in L$, $(\sigma h)(Q) = \sigma\big(h(\eta_1(\sigma)^{-1}Q)\big) = \sigma\big(h(Q)\big)^{\eta_1(\sigma)^{-1}} = h(Q)^{\bar{\chi}_\ell(\sigma)\eta_1(\sigma)^{-1}}$, so G_K acts on $\operatorname{Hom}(L,\mu_\ell)$ by $\bar{\chi}_\ell\eta_1^{-1}$, and $\eta_2 = \bar{\chi}_\ell\eta_1^{-1}$. If L is spanned by a K-rational point, $\eta_1 = 1$ and $\operatorname{Hom}(L,\mu_\ell) \simeq \mu_\ell$. □

Definition 9.34 (Tate modules)**.** For a prime $\ell \neq \operatorname{char} K$, the *$\ell$-adic Tate module* of E is $T_\ell E = \varprojlim_n E[\ell^n]$, the inverse limit along the maps $[\ell]\colon E[\ell^{n+1}] \to E[\ell^n]$, and $V_\ell E = T_\ell E \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$.

Also $E[\ell^\infty] = \bigcup_n E[\ell^n]$. These are the $T_\ell J$ and $V_\ell J$ of Chapter 8 for $J = E$, an elliptic curve being its own Jacobian.

Proposition 9.35 (structure of the Tate module)**.**

(i) *$T_\ell E$ is a free $\mathbb{Z}_\ell$-module of rank 2, and the projection $T_\ell E \to E[\ell^n]$ is surjective with kernel $\ell^n T_\ell E$; so $T_\ell E/\ell^n T_\ell E \simeq E[\ell^n]$.*

(ii) *The map $V_\ell E \to E[\ell^\infty]$, $\ell^{-n}t \mapsto t_n$ (the n-th component of $t \in T_\ell E$), is well defined, surjective, and has kernel $T_\ell E$; so $V_\ell E/T_\ell E \simeq E[\ell^\infty] \simeq (\mathbb{Q}_\ell/\mathbb{Z}_\ell)^2$.*

(iii) *The pairings e_{ℓ^n} assemble into a pairing $e\colon T_\ell E \times T_\ell E \to \mathbb{Z}_\ell(1) = \varprojlim \mu_{\ell^n}$, $e((S_n),(T_n)) = \big(e_{\ell^n}(S_n,T_n)\big)_n$, which is bilinear, alternating, perfect and G_K-equivariant.*

(iv) *Let $\operatorname{char} K = p > 0$ and define $T_pE = \varprojlim_n E[p^n]$ by the same formula ($E[p^n]$ being the group of $\bar{K}$-points killed by p^n). Then T_pE is 0 or $\mathbb{Z}_p$; this rests on Corollary 9.22(iii), which we do not prove.*

Proof. (i) Choose a basis (P_1, Q_1) of $E[\ell] \simeq (\mathbb{Z}/\ell)^2$ and, inductively, P_{n+1}, Q_{n+1} with $\ell P_{n+1} = P_n$, $\ell Q_{n+1} = Q_n$ ($[\ell]$ is surjective). The subgroup $H = \langle P_{n+1}, Q_{n+1}\rangle$ of $E[\ell^{n+1}] \simeq (\mathbb{Z}/\ell^{n+1})^2$ satisfies $\ell H = \langle P_n, Q_n\rangle = E[\ell^n]$ (induction) and $H \supseteq \ell^n H = E[\ell]$, so $\#H = \#\ell H \cdot \#H[\ell] = \ell^{2n}\cdot\ell^2$ and $H = E[\ell^{n+1}]$. In these compatible bases each $E[\ell^n]$ is $(\mathbb{Z}/\ell^n)^2$ and the transition maps are the reductions, so $T_\ell E \simeq \varprojlim (\mathbb{Z}/\ell^n)^2 = \mathbb{Z}_\ell^2$ (Chapter 1), and the projection to the n-th term is reduction modulo ℓ^n. (ii) If $\ell^{-n}t = \ell^{-n'}t'$ with $n' \geq n$ then $t' = \ell^{n'-n}t$, whose n'-th component is $\ell^{n'-n}t_{n'} = t_n$; so the map is well defined. It is surjective by (i), and $\ell^{-n}t \mapsto 0$ iff $t_n = 0$ iff $t \in \ell^n T_\ell E$ iff $\ell^{-n}t \in T_\ell E$. (iii) Compatibility of the components: by Theorem 9.32(v), $e_{\ell^{n+1}}(S_{n+1},T_{n+1})^\ell = e_{\ell^{n+1}}(S_{n+1},\ell T_{n+1}) = e_{\ell^{n+1}}(S_{n+1},T_n) = e_{\ell^n}(\ell S_{n+1},T_n) = e_{\ell^n}(S_n,T_n)$, which is the transition map $\zeta \mapsto \zeta^\ell$ of $\mathbb{Z}_\ell(1)$. Bilinearity, the alternating property and equivariance pass to the limit. For perfectness, choose a generator of $\mathbb{Z}_\ell(1) \simeq \mathbb{Z}_\ell$ and a $\mathbb{Z}_\ell$-basis s, t of $T_\ell E$. Since e is alternating, its Gram matrix is $\left(\begin{smallmatrix} 0 & u \\ -u & 0\end{smallmatrix}\right)$ with $u = e(s,t)$, of determinant u^2. Modulo ℓ the pairing is e_ℓ on the basis s_1, t_1 of $E[\ell]$, and $e_\ell(s_1,t_1)$ is a primitive ℓ-th root of unity (proof of Corollary 9.33(i)); so $u \not\equiv 0 \pmod{\ell}$, $u \in \mathbb{Z}_\ell^\times$, and e is perfect. (iv) Given Corollary 9.22(iii), the same argument as (i) with one generator: either all $E[p^n]$ vanish, or $E[p^n] \simeq \mathbb{Z}/p^n$ with surjective transition maps $[p]$, and the limit is $\mathbb{Z}_p$. □

Definition 9.36 (the ℓ-adic and mod ℓ representations)**.** G_K acts on each $E[\ell^n]$ by group automorphisms (Theorem 9.13(ii)), compatibly with $[\ell]$, hence on $T_\ell E$ and $V_\ell E$. After a choice of $\mathbb{Z}_\ell$-basis of $T_\ell E$ this is a homomorphism

$$\rho_{E,\ell}\colon G_K \to \operatorname{Aut}_{\mathbb{Z}_\ell}(T_\ell E) \simeq \mathrm{GL}_2(\mathbb{Z}_\ell),$$

and its reduction $\bar\rho_{E,\ell}\colon G_K \to \operatorname{Aut}(E[\ell]) \simeq \mathrm{GL}_2(\mathbb{F}_\ell)$ is the action on $E[\ell] = T_\ell E/\ell T_\ell E$; more generally $\rho_{E,\ell} \bmod \ell^k$ is the action on $E[\ell^k]$. Different bases give conjugate homomorphisms.

Proposition 9.37 (properties of $\rho_{E,\ell}$)**.**

(i) *$\rho_{E,\ell}$ is continuous. The field $K(E[\ell^n])$ generated by the coordinates of the points of $E[\ell^n]$ is a finite Galois extension of K, and $\rho_{E,\ell} \bmod \ell^n$ factors through $\mathrm{Gal}(K(E[\ell^n])/K)$, on which it is injective.*

(ii) *$\det \rho_{E,\ell} = \chi_\ell$, the ℓ-adic cyclotomic character, and $\det \bar\rho_{E,\ell} = \bar\chi_\ell$.*

(iii) An isogeny $\varphi\colon E \to E'$ defined over K induces an injective G_K-equivariant map $\varphi_\ell\colon T_\ell E \to T_\ell E'$ with $\operatorname{coker}\varphi_\ell \simeq (\ker\varphi)[\ell^\infty]$. Hence $V_\ell E \simeq V_\ell E'$, and $T_\ell E \simeq T_\ell E'$ as G_K-modules when $\ell \nmid \deg\varphi$.

Proof. (i) $E[\ell^n]$ is finite and G_K-stable (Theorem 9.13(ii)), so its coordinates generate a finite extension L_n stable under G_K, hence Galois, provided it is separable over K. Separability: let $m = \ell^n$ and $P \in E[m] \smallsetminus \{O\}$. If m is odd, $x(P)$ is a root of ψ_m, a polynomial over K whose roots are all simple (Corollary 9.28). If m is even ($\ell = 2 \neq \operatorname{char} K$), either $2P = O$ and $x(P)$ is a root of the cubic F, whose roots are simple (Proposition 9.11(iv)), or $\psi_2(P) \neq 0$, and then $x(P)$ is a root of $f_m = \psi_m/\psi_2$ (Theorem 9.27); the $(m^2-4)/2$ distinct values $x(P)$ for $P \in E[m] \smallsetminus E[2]$ (points paired with their negatives) are roots of f_m, which has that degree and leading coefficient $m/2 \neq 0$ in K (Proposition 9.26), so they are simple roots. A simple root of a polynomial over K is separable over K. Then $y(P)$ is a root of $g(Y) = Y^2 + (a_1x(P) + a_3)Y - (x(P)^3 + a_2x(P)^2 + a_4x(P) + a_6)$, whose derivative at $y(P)$ is $\psi_2(P)$; if $\psi_2(P) \neq 0$ it is a simple root, hence separable over $K(x(P))$, and if $\psi_2(P) = 0$ (so $\operatorname{char} K \neq 2$, since in characteristic 2 the prime ℓ is odd and $2P \neq O$) then $y(P) = -(a_1x(P) + a_3)/2 \in K(x(P))$. So the coordinates of the points of $E[\ell^n]$ lie in K^{sep}; this argument does not assume K perfect, as [185, Section III.7] does. An element of G_K acts trivially on $E[\ell^n]$ iff it fixes L_n. So the kernel of $\rho_{E,\ell} \bmod \ell^n$ is the open subgroup G_{L_n}, and the inverse images of the basic open subgroups $\ker(\mathrm{GL}_2(\mathbb{Z}_\ell) \to \mathrm{GL}_2(\mathbb{Z}/\ell^n))$ are open: $\rho_{E,\ell}$ is continuous (Chapter 5). (ii) By Corollary 9.33(i) with $m = \ell^n$ for all n, $\det\rho_{E,\ell}(\sigma) \equiv \chi_\ell(\sigma) \pmod{\ell^n}$ for every n. (iii) φ maps $E[\ell^n]$ to $E'[\ell^n]$ compatibly with $[\ell]$ and with G_K (Theorem 9.19(i), Definition 9.17), so it induces φ_ℓ, and $\varphi_V = \varphi_\ell \otimes \mathbb{Q}_\ell$. As $\hat\varphi \circ \varphi = [\deg\varphi]$ is invertible on $V_\ell E$, φ_V is injective, hence an isomorphism by dimensions, and φ_ℓ is injective. Under the identifications $V/T \simeq E[\ell^\infty]$ of Proposition 9.35(ii), φ_V induces $\varphi\colon E[\ell^\infty] \to E'[\ell^\infty]$, whose kernel is $\varphi_V^{-1}(T_\ell E')/T_\ell E \simeq T_\ell E'/\varphi_\ell(T_\ell E) = \operatorname{coker}\varphi_\ell$ and also equals $(\ker\varphi)[\ell^\infty]$. Finally $\#\ker\varphi$ divides $\deg\varphi$ (Theorem 9.19(ii)), so if $\ell \nmid \deg\varphi$ the cokernel is 0. □

Corollary 9.38 ($T_\ell E$ is self-dual up to a twist)**.** *The Weil pairing gives G_K-isomorphisms*

$$T_\ell E \xrightarrow{\sim} \operatorname{Hom}_{\mathbb{Z}_\ell}(T_\ell E, \mathbb{Z}_\ell(1)) = (T_\ell E)^\vee(1), \quad t \mapsto e(\cdot, t), \qquad E[\ell^k] \simeq \operatorname{Hom}(E[\ell^k], \mu_{\ell^k}).$$

Equivalently $(T_\ell E)^\vee \simeq T_\ell E(-1)$ and $\rho_{E,\ell}^\vee \simeq \rho_{E,\ell} \otimes \chi_\ell^{-1}$, which is the identity $V^\vee \simeq V \otimes \det^{-1}$ for two-dimensional V (Chapter 4). Consequently $\mathrm{ad}^0((T_\ell E)^\vee) \simeq \mathrm{ad}^0(T_\ell E)$ as G_K-modules (Chapter 4): the trace-zero adjoint does not distinguish $T_\ell E$ from its dual, nor from any lattice homothetic to either.

Proof. The map is $\mathbb{Z}_\ell$-linear, bijective because e is perfect (Proposition 9.35(iii)), and equivariant by the computation in the proof of Corollary 9.33(iii) with e in place of e_ℓ. The finite-level statement is the same argument with e_{ℓ^k}. Tensoring with $\mathbb{Z}_\ell(-1)$ gives the second form. Transposition $g \mapsto g^{\mathsf{T}}$ is a $\mathbb{Z}_\ell$-linear bijection $\mathrm{End}(T) \to \mathrm{End}(T^\vee)$ preserving traces, and it is G_K-equivariant because $\rho^\vee(\sigma)g^{\mathsf{T}}\rho^\vee(\sigma)^{-1} = (\rho(\sigma)g\rho(\sigma)^{-1})^{\mathsf{T}}$ for $\rho^\vee(\sigma) = (\rho(\sigma)^{-1})^{\mathsf{T}}$; so $\mathrm{ad}^0(T) \simeq \mathrm{ad}^0(T^\vee)$. Twisting by a character does not change End, hence not ad^0 (Chapter 4). □

Corollary 9.39 (complex conjugation)**.** *Let $E/\mathbb{Q}$, ℓ odd, and $c \in G_{\mathbb{Q}}$ a complex conjugation. Then $\bar\rho_{E,\ell}(c)$ is conjugate in $\mathrm{GL}_2(\mathbb{F}_\ell)$ to $\mathrm{diag}(1,-1)$: it has eigenvalues $1, -1$, trace 0 and determinant -1. The same holds for $\rho_{E,\ell}(c)$ in $\mathrm{GL}_2(\mathbb{Z}_\ell)$.*

Proof. $c^2 = 1$ and $\chi_\ell(c) = -1$, as c inverts roots of unity. A matrix g with $g^2 = 1$ over a ring in which 2 is invertible satisfies $M = M^+ \oplus M^-$ with $M^\pm = \frac{1\pm g}{2}M$, the ±1-eigenspaces; over

$\mathbb{Z}_\ell$ (or $\mathbb{F}_\ell$) both are free, of ranks adding to 2. Since $\det g = -1$, $g \neq \pm 1$, so both ranks are 1. (Directly: $E(\mathbb{R})$ is a compact real Lie group of dimension one, S^1 or $S^1 \times \mathbb{Z}/2$, so its ℓ-torsion $E[\ell]^c$ is cyclic of order ℓ.) □

Convention 9.40 (Frobenius)**.**

(a) For E over a finite field $\mathbb{F}_\mathfrak{q}$, the *Frobenius endomorphism* $\pi = \pi_\mathfrak{q}\colon (x, y) \mapsto (x^\mathfrak{q}, y^\mathfrak{q})$ acts on $E(\overline{\mathbb{F}}_p)$ exactly as the arithmetic Frobenius $\mathrm{Frob}_\mathfrak{q} \in G_{\mathbb{F}_\mathfrak{q}}$, $t \mapsto t^\mathfrak{q}$.

(b) For $E/\mathbb{Q}$ with good reduction at $p \neq \ell$, Frob_p in a group-theoretic statement is an *arithmetic* Frobenius at p (Chapter 6), and Frob_p^{-1} is a geometric one. $\rho_{E,\ell}(\mathrm{Frob}_p)$ has characteristic polynomial $X^2 - a_p X + p$ (Theorem 9.67); its roots α_p, β_p satisfy $\alpha_p \beta_p = p$.

(c) On the dual $V_\ell E^\vee = H^1$ the geometric Frobenius has the eigenvalues α_p, β_p (the inverse transpose of $\rho(\mathrm{Frob}_p)$ has eigenvalues $\alpha_p^{-1}, \beta_p^{-1}$, and Frob_p^{-1} inverts them again), while on $V_\ell E$ itself the geometric Frobenius has the eigenvalues $\alpha_p^{-1} = \beta_p/p$ and $\beta_p^{-1} = \alpha_p/p$. Local L-factors are defined with the geometric Frobenius (Appendix B, Appendix B): $L_p(M, s) = \det(1 - \mathrm{Frob}_p^{-1}\, p^{-s} \mid M^{I_p})^{-1}$. Hence, at a prime p of good reduction,

$$L_p(E, s) = \det(1 - \mathrm{Frob}_p\ p^{-s} \mid V_\ell E)^{-1} = L_p(V_\ell E^\vee, s) = (1 - a_p p^{-s} + p^{1-2s})^{-1},$$

$$L_p(V_\ell E, s) = L_p(E, s+1),$$

the last because $\det(1 - \mathrm{Frob}_p^{-1}\, X \mid V_\ell E) = (1 - \beta_p X/p)(1 - \alpha_p X/p)$, or because $V_\ell E \simeq V_\ell E^\vee(1)$ (Corollary 9.38).

(d) On $\mathrm{ad}^0 V_\ell E$ both Frobenii have the eigenvalues $\alpha_p/\beta_p, 1, \beta_p/\alpha_p$, so the good factor of the adjoint does not depend on the convention; at a multiplicative prime it does (on the invariant line the arithmetic Frobenius acts by q, the geometric one by q^{-1}), and the paper's factor $1 - q^{-1-s}$ is the geometric one (Chapters 7 and 19).

A numerical illustration of (b) to (d). For `11a1` at $p = 2$, $a_2 = -2$ (Example 9.68), so $X^2 + 2X + 2$ has roots $\alpha_2 = -1 + i$, $\beta_2 = -1 - i$, with $\alpha_2\beta_2 = 2$ and $|\alpha_2| = \sqrt{2}$. The arithmetic Frobenius has eigenvalues $-1 \pm i$ on $V_\ell E$; the geometric Frobenius has eigenvalues $\alpha_2^{-1} = \frac{-1-i}{2} = \beta_2/2$ and $\beta_2^{-1} = \alpha_2/2$ on $V_\ell E$, and $-1 \pm i$ on $V_\ell E^\vee$. So $L_2(E, s) = \big((1-\alpha_2 2^{-s})(1-\beta_2 2^{-s})\big)^{-1} = (1 + 2\cdot 2^{-s} + 2\cdot 2^{-2s})^{-1}$, while $L_2(V_\ell E, s)$ has the eigenvalues divided by 2, which is the shift $s \mapsto s+1$. On $\mathrm{ad}^0 V_\ell E$ the eigenvalues are $\alpha_2/\beta_2 = -i$, 1 and $\beta_2/\alpha_2 = i$ for either Frobenius. Mixing up the two conventions would replace $L_2(E, s)$ by $L_2(E, s+1)$, a shift that is invisible in the adjoint factor at good primes but not at multiplicative ones, where the paper's factor $1 - q^{-1-s}$ is the geometric one.

In the paper 9.41. Section 1.1 of the paper ("Let $V = V_\ell E$, $T = T_\ell E$, $\rho = \rho_{E,\ell}$, $\bar\rho$ its reduction") uses Definitions 9.34 and 9.36 and Propositions 9.35 and 9.37; the paper states the same Frobenius conventions as Convention 9.40. In Section 4.2 and after Proposition prop:pullback the paper identifies the lattice $M_{f,\lambda}$ of Diamond, Flach and Guo with $H^1(E, \mathbb{Z}_\ell)$, using its Proposition prop:integral, which identifies their integral structure with $H^1(X_0(N), \mathbb{Z}_\ell)$ with no localisation (Chapter 14). That module is $\mathrm{Hom}(T_\ell E, \mathbb{Z}_\ell) = (T_\ell E)^\vee$, which by Corollary 9.38 is $T_\ell E(-1)$: the dual of $T_\ell E$, not $T_\ell E$ itself. Since the adjoint is insensitive to duals and twists, $\mathrm{ad}^0 M_{f,\lambda} = \mathrm{ad}^0 T_\ell E$, which is all the paper uses. Lemma lem:h0 uses that complex conjugation has distinct eigenvalues ± 1 (Corollary 9.39), which makes an irreducible $\bar\rho$ absolutely irreducible (Chapter 11), and $\det \rho = \chi_\ell$ (Proposition 9.37(ii)) in the determinant argument; Proposition prop:ns uses $\det \bar\rho_{E,3} = \bar\chi_3 = \chi_{-3}$.

9.6 Endomorphisms and complex multiplication

Curves with complex multiplication are the exceptions of the paper: Conjecture conj:eis and the data sections exclude them, Proposition prop:no9 reaches a contradiction by producing complex multiplication, and the theorem of Calegari and Emerton quoted in Section sec:two has a CM alternative. This section records the structure of endomorphism rings, the Galois action on the endomorphisms of a CM curve over $\mathbb{Q}$, the thirteen rational CM j-invariants, and the facts about a_p that recognise CM. The number-theoretic side (orders, class number one, splitting of primes) is Chapter 6.

Theorem 9.42 (endomorphism rings)**.** $\mathrm{End}_{\bar{K}}(E)$ *has no zero divisors, and* deg *is a positive definite quadratic form on it. As a ring it is isomorphic to* $\mathbb{Z}$*, to an order in an imaginary quadratic field, or, only when* $\operatorname{char} K = p > 0$*, to a maximal order in the quaternion algebra over* $\mathbb{Q}$ *ramified exactly at* p *and* ∞*. In characteristic* 0 *only the first two occur.*

The first sentence follows from Theorem 9.21(iv) and the multiplicativity of degrees. We do not prove the classification; see [185, Sections III.9 and V.3]. Over $\mathbb{C}$ the dichotomy $\mathbb{Z}$ or an imaginary quadratic order is proved in Proposition 9.55(iii), and every field of characteristic 0 over which a given E and its endomorphisms are defined embeds into $\mathbb{C}$.

Proposition 9.43 (normalised endomorphisms and the Galois action)**.** *Let* $\operatorname{char} K = 0$ *and* ω *the invariant differential of* E*.*

(i) The map $\mathrm{End}_{\bar{K}}(E) \to \bar{K}$*,* $\alpha \mapsto c_\alpha$ *where* $\alpha^*\omega = c_\alpha\omega$*, is an injective ring homomorphism. Its image* $\mathcal{O}$ *is* $\mathbb{Z}$ *or an order in an imaginary quadratic field* $F \subset \bar{K}$*; we write* $[c]$ *for the endomorphism with* $c_{[c]} = c$*, consistently with* $[m]$ *for* $m \in \mathbb{Z}$*.*

(ii) An endomorphism defined over K *has* $c_\alpha \in K$*. In particular* $\mathrm{End}_{\mathbb{Q}}(E) = \mathbb{Z}$ *for every* $E/\mathbb{Q}$*.*

(iii) Let $E/\mathbb{Q}$ *and* $\mathrm{End}_{\overline{\mathbb{Q}}}(E) = \mathcal{O} \neq \mathbb{Z}$*, with fraction field* F*. For* $\sigma \in G_{\mathbb{Q}}$ *and* $c \in \mathcal{O}$*,* $\sigma\circ[c]\circ\sigma^{-1} = [\sigma(c)]$ *on* $E(\overline{\mathbb{Q}})$*. So every endomorphism is defined over* F*, and* σ *acts on* $\mathcal{O}$ *by complex conjugation when* $\sigma|_F \neq 1$*. On the Tate module,* $\rho_{E,\ell}(\sigma)\,[c]_\ell\,\rho_{E,\ell}(\sigma)^{-1} = [\sigma(c)]_\ell$*.*

Proof. (i) Additivity is Proposition 9.15(iii), and $(\alpha\circ\beta)^*\omega = \beta^*(c_\alpha\omega) = c_\alpha c_\beta\omega$. Every holomorphic differential is a constant multiple of ω (Chapter 8), so c_α is defined. A nonzero α is separable (characteristic 0), so $\alpha^*\omega \neq 0$ (Chapter 8): the map is injective. Its image is a commutative ring isomorphic to $\mathrm{End}_{\bar{K}}(E)$, so by Theorem 9.42 it is $\mathbb{Z}$ or an imaginary quadratic order. (ii) If α is defined over K, then $\alpha^*\omega$ is a differential over K and ω is one, so $c_\alpha \in K$. For $K = \mathbb{Q}$, c_α is a rational number integral over $\mathbb{Z}$ (it lies in an order), hence an integer m, and $\alpha = [m]$ by injectivity. (iii) For $\sigma \in G_{\mathbb{Q}}$ let α^σ be the endomorphism obtained by applying σ to the coefficients of the rational functions defining α; on points, $\alpha^\sigma(P) = \sigma(\alpha(\sigma^{-1}P))$. Applying σ to $\alpha^*\omega = c_\alpha\omega$, and using that ω has rational coefficients, gives $(\alpha^\sigma)^*\omega = \sigma(c_\alpha)\omega$; so $[c]^\sigma = [\sigma(c)]$ by (i). If $\sigma|_F = 1$ this gives $[c]^\sigma = [c]$ for all c, so every endomorphism is defined over F (Chapter 8). The statement on $T_\ell E$ is the same identity applied to ℓ-power torsion points. □

Definition 9.44 (complex multiplication)**.** An elliptic curve E over a field of characteristic 0 has *complex multiplication* (*CM*) if $\mathrm{End}_{\bar{K}}(E) \neq \mathbb{Z}$. Then $\mathrm{End}_{\bar{K}}(E) \simeq \mathcal{O}$, an order in an imaginary quadratic field F (Proposition 9.43), and E has *CM by* $\mathcal{O}$, or *by* F.

Lemma 9.45 (CM is an isogeny invariant)**.** *If $\varphi\colon E \to E'$ is a nonconstant isogeny of degree n, then $\alpha \mapsto \frac{1}{n}\varphi\circ\alpha\circ\hat{\varphi}$ is an isomorphism of $\mathbb{Q}$-algebras $\mathrm{End}(E)\otimes\mathbb{Q} \to \mathrm{End}(E')\otimes\mathbb{Q}$. In particular E has CM iff E' has, and then by the same field F.*

Proof. $\frac{1}{n^2}(\varphi\alpha\hat{\varphi})(\varphi\beta\hat{\varphi}) = \frac{1}{n^2}\varphi\alpha[n]\beta\hat{\varphi} = \frac{1}{n}\varphi\alpha\beta\hat{\varphi}$ (Theorem 9.21), additivity is clear, and $1 \mapsto \frac{1}{n}\varphi\hat{\varphi} = 1$. The map $\beta \mapsto \frac{1}{n}\hat{\varphi}\beta\varphi$ in the other direction is inverse to it, by the same computation. □

Theorem 9.46 (the rational CM j-invariants)**.** *If $E/\mathbb{Q}$ has CM by the order $\mathcal{O}$, then $\mathcal{O}$ has class number one, so its discriminant $D_{\mathcal{O}}$ is one of the thirteen values in the table below, and $j(E)$ is the corresponding value; conversely each value is the j-invariant of a curve over $\mathbb{Q}$ with CM by that order. Here $j(E) = j(\tau)$ for $\tau = \frac{D_{\mathcal{O}}+\sqrt{D_{\mathcal{O}}}}{2}$ (Section 9.7).*

$D_{\mathcal{O}}$	j	*example*	$D_{\mathcal{O}}$	j	*example*
-3	0	*27a1, 36a1*	-19	$-884736 = -2^{15}3^3$	
-4	1728	*32a1*	-27	$-12288000 = -2^{15}\cdot 3\cdot 5^3$	*27a2, 27a4*
-7	$-3375 = -3^3 5^3$		-28	$16581375 = 3^3 5^3 17^3$	
-8	$8000 = 2^6 5^3$		-43	$-884736000 = -2^{18}3^3 5^3$	
-11	$-32768 = -2^{15}$	*121b1*	-67	$-147197952000 = -2^{15}3^3 5^3 11^3$	
-12	$54000 = 2^4 3^3 5^3$		-163	$-262537412640768000 = -2^{18}3^3 5^3 23^3 29^3$	
-16	$287496 = 2^3 3^3 11^3$				

We do not prove this; see [185, Appendix C, Section 11], [184, Chapter II] and [34, Sections 7 and 10 to 12]. The ingredients are: $j(E)$ generates the ring class field of $\mathcal{O}$ over F, of degree $h(\mathcal{O})$ (so $j(E)\in\mathbb{Q}$ forces $h(\mathcal{O}) = 1$), and the theorem of Heegner, Baker and Stark (Chapter 6) lists the orders of class number one. The thirteen values were checked numerically as $j(\tau)$ with PARI's `ellj`, and the examples' j-invariants with `ellinit`.

Theorem 9.47 (CM and the numbers a_p)**.** *Let $E/\mathbb{Q}$ have CM by an order in the imaginary quadratic field F, and let χ_F be the quadratic character of F.*

(i) $\rho_{E,\ell} \simeq \rho_{E,\ell}\otimes\chi_F$ *for every prime ℓ.*

(ii) $a_p(E) = 0$ *for every prime p of good reduction that is inert in F (the reduction is supersingular, Definition 9.64).*

(iii) For a prime p of good reduction that splits in F, there is π_p in the ring of integers of F with $\pi_p\bar{\pi}_p = p$ and $a_p(E) = \pi_p + \bar{\pi}_p \neq 0$.

(iv) Every prime ramified in F divides the conductor N of E. In particular, if E has CM by $\mathbb{Q}(\sqrt{\ell^*})$ for an odd prime ℓ, then $\ell \mid N$.

(v) Conversely, if $a_p(E) = 0$ for all primes p inert in an imaginary quadratic field F outside a set of density 0, then E has CM by F.

Sketch of proof. (i), (ii) and (iv) are proved in Chapter 6 from Proposition 9.43(iii) and Theorem 9.67; we recall the argument. Choose $0 \neq c \in \mathcal{O}$ with $\bar{c} = -c$; for instance $c = \sqrt{D_{\mathcal{O}}}$, which lies in $\mathcal{O} = \mathbb{Z}\big[\frac{D_{\mathcal{O}}+\sqrt{D_{\mathcal{O}}}}{2}\big]$ as $2\cdot\frac{D_{\mathcal{O}}+\sqrt{D_{\mathcal{O}}}}{2} - D_{\mathcal{O}}$. For $\sigma\in G_{\mathbb{Q}}$, $\sigma(c) = c$ if σ is trivial on F and $\sigma(c) = \bar{c} = -c$ otherwise, that is, $\sigma(c) = \chi_F(\sigma)c$. By Proposition 9.43(iii), $\rho(\sigma)[c]_\ell\rho(\sigma)^{-1} = [\chi_F(\sigma)c]_\ell = \chi_F(\sigma)[c]_\ell$, so the map $[c]_\ell$ on $V_\ell E$, invertible because $[\bar{c}]\circ[c] = [c\bar{c}]$ is multiplication by the nonzero integer $c\bar{c}$, satisfies $[c]_\ell\rho(\sigma) = \chi_F(\sigma)\rho(\sigma)[c]_\ell$: it is an isomorphism $\rho \to \rho\otimes\chi_F$. Taking traces, $\mathrm{tr}\,\rho(\sigma) = \chi_F(\sigma)\,\mathrm{tr}\,\rho(\sigma)$, and at a good $p\neq\ell$ inert in F,

$\chi_F(\mathrm{Frob}_p) = -1$ gives $a_p = \operatorname{tr}\rho(\mathrm{Frob}_p) = 0$ (Theorem 9.67). For (iv): if p ramified in F were a prime of good reduction, take $\ell \neq p$; ρ is unramified at p (Theorem 9.67), but some $\tau \in I_p$ has $\chi_F(\tau) = -1$, and then $[c]_\ell = \rho(\tau)[c]_\ell\rho(\tau)^{-1} = -[c]_\ell$, a contradiction. (iii) is Deuring's theorem [46]: the reduction is ordinary, its endomorphism ring contains the reduction of $\mathcal{O}$ and is an order of F, and the Frobenius endomorphism π_p (Definition 9.60) is an element of norm p with trace a_p; see [184, Chapter II, Section 10]. (v) follows from Serre's open image theorem (Chapter 11); see [178]. □

The checks: $a_p = 0$ at every good inert $p < 500$ and $a_p \neq 0$ at every good split $p < 500$ for `27a1`, `36a1` ($F = \mathbb{Q}(\sqrt{-3})$), `32a1` ($F = \mathbb{Q}(i)$) and `121b1` ($F = \mathbb{Q}(\sqrt{-11})$); and among the 462 curves of conductor below 10,000 with one of the thirteen j-invariants, every prime dividing the discriminant of F divides the conductor, as (iv) says.

Warning 9.48 (the cyclotomic character is not a quadratic character). The CM condition of Theorem 9.47(i) involves the quadratic character χ_F; for $F = \mathbb{Q}(\sqrt{\ell^*})$ this is $\chi_{\ell^*} = \bar{\chi}_\ell^{(\ell-1)/2}$. The cyclotomic character χ_ℓ is not quadratic, and $\rho_{E,\ell} \simeq \rho_{E,\ell} \otimes \chi_\ell$ is impossible for every E (determinants give $\chi_\ell^2 = 1$). Only for $\ell = 3$ do $\bar{\chi}_\ell$ and χ_{ℓ^*} coincide: $\bar{\chi}_3 = \chi_{-3}$. The paper's Lemma lem:h0 works with $\bar{\chi}_\ell$. By Theorem 9.47(iv) a curve $E/\mathbb{Q}$ with $\ell \nmid N$ has no CM by $\mathbb{Q}(\sqrt{\ell^*})$.

In the paper 9.49. The paper excludes CM curves in Conjecture conj:eis and in its data ("not CM"). Proposition prop:no9 (Proposition 9.78 below) ends with "so E', hence E, has complex multiplication": the passage from E' to E is Lemma 9.45. The CM alternative in the theorem of Calegari and Emerton (Section sec:two: "it has complex multiplication and $N \in \{27, 32, 49, 243\}$") concerns CM curves of these four conductors; the optimal curves `27a1`, `32a1`, `49a1` and `243b1`, of modular degrees 1, 1, 1 and 9 (`degphi`), have $j = 0$, 1728, -3375 and 0, that is, CM by the orders of discriminant -3, -4, -7, -3 (Theorem 9.46). The paper's examples are `27a1` and `243b1`.

9.7 Elliptic curves over the complex numbers

Section 1 of the paper describes the modular degree as "$\langle f, f\rangle$ divided by the area of the period lattice of E" (Zagier, Watkins; the exact formula, with the Manin constant, is in Chapter 14). This section constructs the period lattice: it proves that every elliptic curve over $\mathbb{C}$ is a torus $\mathbb{C}/\Lambda$, through the Weierstrass function $\wp$, that isomorphism classes of curves over $\mathbb{C}$ correspond to lattices up to homothety and to points of $\mathrm{SL}_2(\mathbb{Z})\backslash\mathcal{H}$, and computes the periods of `11a1`. The analysis is that of Appendix A: a doubly periodic function is, in the language of physics, a function on a torus, and the Weierstrass function plays for the torus the role that a Fourier series plays for the circle.

Definition 9.50 (lattices)**.** A *lattice* is a subgroup $\Lambda = \mathbb{Z}\omega_1 + \mathbb{Z}\omega_2 \subset \mathbb{C}$ with ω_1, ω_2 linearly independent over $\mathbb{R}$; the basis is *oriented* if $\mathrm{Im}(\omega_2/\omega_1) > 0$. Lattices Λ, Λ' are *homothetic* if $\Lambda' = c\Lambda$ for some $c \in \mathbb{C}^\times$. The *covolume* $\mathrm{vol}(\Lambda) = |\mathrm{Im}(\bar{\omega}_1\omega_2)|$ is the area of a fundamental parallelogram. For $k \geq 2$ the *Eisenstein series* of Λ is $G_{2k}(\Lambda) = \sum_{\omega\in\Lambda\smallsetminus\{0\}} \omega^{-2k}$, and

$$g_2(\Lambda) = 60G_4(\Lambda), \qquad g_3(\Lambda) = 140G_6(\Lambda), \qquad \Delta(\Lambda) = g_2^3 - 27g_3^2, \qquad j(\Lambda) = 1728\frac{g_2^3}{\Delta(\Lambda)}.$$

Lemma 9.51 (lattice sums)**.** *$\sum_{\omega\in\Lambda\smallsetminus\{0\}}|\omega|^{-s}$ converges for every real $s>2$. Hence $G_{2k}(\Lambda)$ converges absolutely for $k\geq 2$, and $G_{2k}(c\Lambda)=c^{-2k}G_{2k}(\Lambda)$, $g_2(c\Lambda)=c^{-4}g_2(\Lambda)$, $g_3(c\Lambda)=c^{-6}g_3(\Lambda)$, $\Delta(c\Lambda)=c^{-12}\Delta(\Lambda)$, and $j(c\Lambda)=j(\Lambda)$ (once $\Delta(\Lambda)\neq 0$ is known, Theorem 9.52).*

Proof. The function $(a,b)\mapsto|a\omega_1+b\omega_2|$ is continuous and positive on the compact subset of $\mathbb{R}^2$ where $\max(|a|,|b|)=1$, so it has a minimum $\mu>0$ there; by homogeneity $|a\omega_1+b\omega_2|\geq\mu n$ when $\max(|a|,|b|)=n$. There are $8n$ pairs of integers with $\max(|a|,|b|)=n$, so the sum is at most $\sum_{n\geq1}8n(\mu n)^{-s}$, which converges for $s>2$. The homogeneity is clear from the definitions. □

Theorem 9.52 (the Weierstrass function)**.** *Let Λ be a lattice and*

$$\wp(z)=\wp(z;\Lambda)=\frac{1}{z^2}+\sum_{\omega\in\Lambda\smallsetminus\{0\}}\Big(\frac{1}{(z-\omega)^2}-\frac{1}{\omega^2}\Big).$$

(i) The series converges absolutely and uniformly on compact subsets of $\mathbb{C}\smallsetminus\Lambda$; $\wp$ is meromorphic on $\mathbb{C}$, even, Λ-periodic, with a double pole at each point of Λ and no other pole.

(ii) Near 0, $\wp(z)=z^{-2}+\sum_{k\geq1}(2k+1)G_{2k+2}(\Lambda)z^{2k}$.

(iii) $\wp'(z)^2=4\wp(z)^3-g_2(\Lambda)\wp(z)-g_3(\Lambda)$.

(iv) The values $e_1=\wp(\omega_1/2)$, $e_2=\wp(\omega_2/2)$, $e_3=\wp((\omega_1+\omega_2)/2)$ are the three roots of $4x^3-g_2x-g_3$, and they are distinct; hence $\Delta(\Lambda)=16\prod_{i<j}(e_i-e_j)^2\neq0$.

(v) A Λ-periodic meromorphic function whose poles lie in Λ and have order at most 2 is $a\wp+b$ with $a,b\in\mathbb{C}$; if the poles have order at most 3, it is $a\wp'+b\wp+c$.

Proof. (i) For $|z|\leq R$ and $|\omega|\geq 2R$, $|(z-\omega)^{-2}-\omega^{-2}|=|z(2\omega-z)|/|\omega^2(z-\omega)^2|\leq R\cdot\frac{5}{2}|\omega|\cdot|\omega|^{-2}\cdot4|\omega|^{-2}=10R|\omega|^{-3}$, and $\sum|\omega|^{-3}<\infty$ (Lemma 9.51). The finitely many terms with $|\omega|<2R$ are meromorphic. So the series converges normally on compact sets avoiding Λ and $\wp$ is meromorphic (Appendix A, Weierstrass's theorem on uniform limits), with poles exactly at Λ, double. Replacing ω by $-\omega$ shows $\wp(-z)=\wp(z)$. Differentiating termwise, $\wp'(z)=-2\sum_{\omega\in\Lambda}(z-\omega)^{-3}$, which is visibly Λ-periodic; so $\wp(z+\omega_i)-\wp(z)$ is a constant C_i, and evaluating at $z=-\omega_i/2$ (not a pole) gives $C_i=\wp(\omega_i/2)-\wp(-\omega_i/2)=0$. (ii) For $|z|<\min|\omega|$, $(z-\omega)^{-2}-\omega^{-2}=\sum_{n\geq1}(n+1)z^n\omega^{-n-2}$; summing over ω (absolutely convergent) the odd powers cancel in pairs $\pm\omega$, and the coefficient of z^{2k} is $(2k+1)G_{2k+2}$. (iii) From (ii), $\wp=z^{-2}+3G_4z^2+5G_6z^4+O(z^6)$ and $\wp'=-2z^{-3}+6G_4z+20G_6z^3+O(z^5)$, so $\wp'^2=4z^{-6}-24G_4z^{-2}-80G_6+O(z^2)$ and $4\wp^3=4(z^{-6}+9G_4z^{-2}+15G_6+O(z^2))=4z^{-6}+36G_4z^{-2}+60G_6+O(z^2)$. Hence $\wp'^2-4\wp^3=-60G_4z^{-2}-140G_6+O(z^2)$, and adding $60G_4\wp=60G_4z^{-2}+O(z^2)$ gives $\wp'^2-4\wp^3+60G_4\wp+140G_6=O(z^2)$, that is, $\wp'^2-4\wp^3+g_2\wp+g_3=O(z^2)$; this is where the normalisations $g_2=60G_4$, $g_3=140G_6$ come from. The left side is Λ-periodic and holomorphic away from Λ, and by this expansion holomorphic at 0 and vanishing there; a holomorphic doubly periodic function is bounded, hence constant (Liouville), and the constant is 0. (iv) $\wp'$ is odd and periodic, so $\wp'(\omega_i/2)=-\wp'(-\omega_i/2)=-\wp'(\omega_i/2)$ vanishes at each half-period, and (iii) shows that the e_i are roots of $4x^3-g_2x-g_3$. On the compact Riemann surface $\mathbb{C}/\Lambda$, $\wp-e_i$ has a single pole, of order 2, so it has exactly two zeros counted with multiplicity (Chapter 8); the half-period h_i with $\wp(h_i)=e_i$ is a zero of order at least 2 since $\wp'(h_i)=0$, so it is the only zero. As the three half-periods are distinct modulo Λ, the e_i are distinct. The discriminant of a cubic ax^3+cx+d is $-4ac^3-27a^2d^2$, which for $4x^3-g_2x-g_3$ is $16g_2^3-432g_3^2=16(g_2^3-27g_3^2)$; it is

also $a^4\prod_{i<j}(e_i-e_j)^2 = 4^4\prod_{i<j}(e_i-e_j)^2$. Dividing by 16 gives the formula for $\Delta(\Lambda)$. (v) If f has poles of order at most 2 at the points of Λ, choose a so that $f - a\wp$ has at most a simple pole at 0. The residues of a periodic meromorphic function on $\mathbb{C}/\Lambda$ sum to 0 (Chapter 8, residue theorem), so $f - a\wp$ has no pole; it is holomorphic and doubly periodic, hence constant. The case of order 3 is the same, subtracting first a multiple of $\wp'$, which has a triple pole at 0. □

Theorem 9.53 (complex uniformisation)**.**

(i) Let Λ be a lattice and E_Λ the curve $y^2 = 4x^3 - g_2(\Lambda)x - g_3(\Lambda)$ (a Weierstrass curve after $y \mapsto 2y$; it is smooth by Theorem 9.52(iv)). The map $\Theta\colon \mathbb{C}/\Lambda \to E_\Lambda(\mathbb{C})$, $z \mapsto (\wp(z), \wp'(z))$ for $z \notin \Lambda$ and $0 \mapsto O$, is a biholomorphic group isomorphism, and $\Theta^*(dx/y) = dz$.

(ii) Let E be an elliptic curve over $\mathbb{C}$ with invariant differential ω, and $\Lambda_E = \{\int_\gamma \omega : \gamma \in H_1(E(\mathbb{C}),\mathbb{Z})\}$ its lattice of periods. Then $E \simeq E_{\Lambda_E}$, by an isomorphism that matches ω with dx/y, so $E(\mathbb{C}) \simeq \mathbb{C}/\Lambda_E$ with $\omega \leftrightarrow dz$. Equivalently: for $A, B \in \mathbb{C}$ with $4A^3 + 27B^2 \neq 0$ there is a unique lattice Λ with $g_2(\Lambda) = -4A$ and $g_3(\Lambda) = -4B$.

Proof. (i) Θ is holomorphic (in the chart $(x/y, 1/y)$ near O it is $z \mapsto (\wp/\wp', 1/\wp') = (-z/2 + O(z^5), -z^3/2 + O(z^7))$, holomorphic and sending 0 to $(0,0)$) and lands in E_Λ by Theorem 9.52(iii). It is bijective: O has the single preimage 0, and for an affine point (x_0, y_0) the function $\wp - x_0$ has exactly two zeros $\pm z_0$ modulo Λ (counted with multiplicity, as in the proof of Theorem 9.52(iv)); since $\wp'(-z_0) = -\wp'(z_0)$ and $\wp'(z_0)^2 = y_0^2$, exactly one of $z_0, -z_0$ maps to (x_0, y_0), and if $z_0 \equiv -z_0$ then $y_0 = \wp'(z_0) = 0$. A holomorphic bijection of compact Riemann surfaces is biholomorphic (Chapter 8). Group law: let $z_1, z_2 \in \mathbb{C}$ with $\Theta(z_1)$, $\Theta(z_2)$ affine, distinct and not opposite, and let $y = \lambda x + \nu$ be the line through them. Then $f = \wp' - \lambda\wp - \nu$ is periodic with a single pole, of order 3, at 0 modulo Λ, so it has three zeros z_1, z_2, z_3 modulo Λ, and $z_1 + z_2 + z_3 \in \Lambda$ (the "only if" half of Abel's theorem, Chapter 8, for the torus: the sum of the zeros minus the sum of the poles of a periodic function lies in Λ). The three intersections of the line with E_Λ are $\Theta(z_1), \Theta(z_2), \Theta(z_3)$, so $\Theta(z_1) + \Theta(z_2) = -\Theta(z_3) = \Theta(-z_3) = \Theta(z_1 + z_2)$ (Construction 9.10; on E_Λ, $-(x,y) = (x,-y)$, and $\wp$ is even, $\wp'$ odd). The remaining cases follow by continuity, since $\Theta(z_1+z_2) - \Theta(z_1) - \Theta(z_2)$ is continuous in (z_1, z_2) and vanishes on a dense set. Finally $\Theta^*(dx/y) = \wp'(z)dz/\wp'(z) = dz$.

(ii) We use the Abel-Jacobi theorem of Chapter 8: $E(\mathbb{C})$ is a compact Riemann surface of genus one, ω spans its holomorphic differentials, Λ_E is a lattice, and $\iota\colon E(\mathbb{C}) \to \mathbb{C}/\Lambda_E$, $P \mapsto \int_O^P \omega$, is biholomorphic. It is a homomorphism: $\iota(P)$ is the Abel-Jacobi image of $(P) - (O)$, the Abel-Jacobi map is additive on divisors of degree 0 and kills principal divisors, and $(P+Q) - (O) \sim (P) - (O) + (Q) - (O)$ (Proposition 9.12). Since $d\iota = \omega$, $(\iota^{-1})^*\omega = dz$. Put $\eta = 2y + a_1x + a_3$, so that $\eta^2 = F(x) = 4x^3 + b_2x^2 + 2b_4x + b_6$ (Lemma 9.3), and let $X(z) = x(\iota^{-1}(z))$, $H(z) = \eta(\iota^{-1}(z))$. These are Λ_E-periodic meromorphic functions with poles only at Λ_E, of orders 2 and 3 (as x and η have poles of orders 2 and 3 at O only), and $dX/dz = H$ because $\omega = dx/\eta$ corresponds to dz. If $X = cz^{-2} + \cdots$ then $H = -2cz^{-3} + \cdots$, and comparing the z^{-6} terms of $H^2 = F(X)$ gives $4c^2 = 4c^3$, so $c = 1$. By Theorem 9.52(v), $X = \wp + r$ for a constant r (with $\wp = \wp(\cdot;\Lambda_E)$), and then $H = \wp'$. So $\wp'^2 = F(\wp + r)$ as functions; since $\wp$ takes infinitely many values, $F(x + r) = 4x^3 - g_2x - g_3$ as polynomials. Hence the change of coordinates $x \mapsto x - r$, $\eta \mapsto \eta$ (of the form of Proposition 9.5, with $u = 1$ after the normalisation $\eta = 2y$) maps E to E_{Λ_E}, and Θ^{-1} composed with it is ι; it matches $\omega = dx/\eta$ with dx/y on E_{Λ_E}. For the second form, apply this to $E\colon y^2 = x^3 + Ax + B$, for which $\eta = 2y$ and $F(x) = 4x^3 + 4Ax + 4B$ has no x^2 term, so $r = 0$ and $g_2 = -4A$, $g_3 = -4B$. Uniqueness: if Λ, Λ' have the same g_2, g_3, then $E_\Lambda = E_{\Lambda'}$, and $\Theta'^{-1} \circ \Theta$ is

a holomorphic group isomorphism $\mathbb{C}/\Lambda \to \mathbb{C}/\Lambda'$ pulling dz back to dz; by Proposition 9.55(i) it is $z \mapsto z$, so $\Lambda = \Lambda'$. □

A second route to (ii) avoids Abel-Jacobi: the function $j\colon \mathcal{H} \to \mathbb{C}$ is surjective (Chapter 12, valence formula), so for given A, B there is a lattice with $j(\Lambda) = j$ of $y^2 = x^3 + Ax + B$, and a homothety adjusts g_2, g_3 [185, Section VI.5]. The book uses the route above, so that Chapter 12 may cite this theorem without circularity.

Remark 9.54 (translation invariance over $\mathbb{C}$). Theorem 9.53(ii) gives a second proof of Proposition 9.15(ii) and (iii) in characteristic 0. Under $E(\mathbb{C}) \simeq \mathbb{C}/\Lambda_E$ the group law is addition, τ_Q is $z \mapsto z + z_Q$, and ω is dz, which translations preserve. For isogenies $\varphi, \psi\colon E' \to E$, Proposition 9.55(i) below writes them as $z \mapsto \alpha z$ and $z \mapsto \beta z$; then $\varphi + \psi$ is $z \mapsto (\alpha + \beta)z$, which pulls dz back to $(\alpha + \beta)\,dz$, the sum of the pullbacks. For a curve over any field of characteristic 0, each identity involves finitely many elements, which generate a field that embeds into $\mathbb{C}$. The proof of Theorem 9.53 used only Proposition 9.12 and Chapter 8, not Proposition 9.15.

Proposition 9.55 (maps between complex tori)**.** *Let $\Lambda_1, \Lambda_2, \Lambda$ be lattices.*

(i) The holomorphic maps $\mathbb{C}/\Lambda_1 \to \mathbb{C}/\Lambda_2$ sending 0 to 0 are the maps $z \mapsto \alpha z$ with $\alpha \in \mathbb{C}$, $\alpha\Lambda_1 \subseteq \Lambda_2$. They are group homomorphisms, and isomorphisms iff $\alpha\Lambda_1 = \Lambda_2$. Hence $E_{\Lambda_1} \simeq E_{\Lambda_2}$ over $\mathbb{C}$ iff Λ_1 and Λ_2 are homothetic, and isogenies $E_{\Lambda_1} \to E_{\Lambda_2}$ correspond to such α.

(ii) For $\alpha \neq 0$ the map has degree $[\Lambda_2 : \alpha\Lambda_1]$ and kernel $\alpha^{-1}\Lambda_2/\Lambda_1$. For $\alpha = m$: $\deg[m] = m^2$ and $E[m] = \frac{1}{m}\Lambda/\Lambda \simeq (\mathbb{Z}/m)^2$.

(iii) $\mathrm{End}(\mathbb{C}/\Lambda) = \{\alpha \in \mathbb{C} : \alpha\Lambda \subseteq \Lambda\}$ is $\mathbb{Z}$ or an order in an imaginary quadratic field; the latter happens iff $\tau = \omega_2/\omega_1$ is an imaginary quadratic number, and then the order lies in $\mathbb{Q}(\tau)$.

(iv) For a basis (ω_1, ω_2) of Λ, $e_m(a\frac{\omega_1}{m} + b\frac{\omega_2}{m}, c\frac{\omega_1}{m} + d\frac{\omega_2}{m}) = \zeta^{ad-bc}$, where $\zeta = e_m(\frac{\omega_1}{m}, \frac{\omega_2}{m})$ is a primitive m-th root of unity. For an oriented basis $\zeta = e^{\pm 2\pi i/m}$, the sign depending only on the normalisation of e_m (Convention 9.1(f)); nothing in the book depends on it.

Proof. (i) A holomorphic $f\colon \mathbb{C}/\Lambda_1 \to \mathbb{C}/\Lambda_2$ with $f(0) = 0$ lifts to a holomorphic $F\colon \mathbb{C} \to \mathbb{C}$ with $F(0) = 0$ ($\mathbb{C}$ is simply connected and $\mathbb{C} \to \mathbb{C}/\Lambda_2$ is a covering). For $\omega \in \Lambda_1$, $F(z+\omega) - F(z) \in \Lambda_2$ is continuous in z, hence constant; so F' is Λ_1-periodic and entire, hence constant by Liouville, and $F(z) = \alpha z$ with $\alpha\Lambda_1 \subseteq \Lambda_2$. Conversely such α define holomorphic homomorphisms, with inverse of the same kind iff $\alpha\Lambda_1 = \Lambda_2$. By Theorem 9.53 and the fact that holomorphic maps of compact Riemann surfaces of smooth projective curves are algebraic (Chapter 8, Riemann existence and GAGA), isomorphisms and isogenies of the curves are the same as these maps. (ii) The kernel is $\{z : \alpha z \in \Lambda_2\}/\Lambda_1 = \alpha^{-1}\Lambda_2/\Lambda_1$, of order $[\alpha^{-1}\Lambda_2 : \Lambda_1] = [\Lambda_2 : \alpha\Lambda_1]$; a nonconstant holomorphic homomorphism of tori is an unramified covering whose fibres are cosets of the kernel, so its degree is the order of the kernel. For $\alpha = m$, $[\Lambda : m\Lambda] = m^2$. (iii) If $\alpha\Lambda \subseteq \Lambda$, write $\alpha\omega_1 = a\omega_1 + b\omega_2$ and $\alpha\omega_2 = c\omega_1 + d\omega_2$ with $a, b, c, d \in \mathbb{Z}$. Then α is an eigenvalue of $M = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ with eigenvector (ω_1, ω_2), so it is a root of the monic integral polynomial $X^2 - (a+d)X + (ad-bc)$. If α were real, the real and imaginary parts of the eigenvector, which span $\mathbb{R}^2$ because ω_1, ω_2 are $\mathbb{R}$-independent, would both be eigenvectors, so $M = \alpha \cdot 1$ and $\alpha \in \mathbb{Z}$. So either $\alpha \in \mathbb{Z}$, or α is a non-real quadratic integer, and then $b \neq 0$ and $\tau = (\alpha - a)/b \in \mathbb{Q}(\alpha)$ is imaginary quadratic. Conversely if $A\tau^2 + B\tau + C = 0$ with integers $A \neq 0$, B, C, then $A\tau\Lambda_\tau \subseteq \Lambda_\tau$ for $\Lambda_\tau = \mathbb{Z} + \mathbb{Z}\tau$ ($A\tau \cdot \tau = -B\tau - C$), and $A\tau \notin \mathbb{Z}$. The ring $\mathrm{End}(\mathbb{C}/\Lambda)$ is a subring of $\mathbb{C}$ containing $\mathbb{Z}$, of rank

at most 2 over $\mathbb{Z}$ (it embeds into $\Lambda \simeq \mathbb{Z}^2$ by $\alpha \mapsto \alpha\omega_1$), so it is $\mathbb{Z}$ or an order in $\mathbb{Q}(\tau)$. (iv) By Theorem 9.32(i), (ii) and the computation in the proof of Corollary 9.33(i). The value of ζ is computed in [185, Chapter VI, exercises]; it matches the intersection pairing on H_1 up to a universal sign (Chapter 8). □

Theorem 9.56 (moduli of curves over $\mathbb{C}$)**.**

(i) Every lattice is homothetic to $\Lambda_\tau = \mathbb{Z} + \mathbb{Z}\tau$ for some $\tau \in \mathcal{H}$, and Λ_τ, $\Lambda_{\tau'}$ are homothetic iff $\tau' = \frac{a\tau+b}{c\tau+d}$ for some $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$. Hence the isomorphism classes of elliptic curves over $\mathbb{C}$, the homothety classes of lattices, and the points of $\mathrm{SL}_2(\mathbb{Z})\backslash\mathcal{H}$ are in bijection.

(ii) $j(\tau) := j(\Lambda_\tau)$ is holomorphic on $\mathcal{H}$ and $\mathrm{SL}_2(\mathbb{Z})$-invariant, and $j(i) = 1728$, $j(e^{2\pi i/3}) = 0$.

(iii) $j\colon \mathrm{SL}_2(\mathbb{Z})\backslash\mathcal{H} \to \mathbb{C}$ is a bijection, and $j(\tau) = q^{-1} + 744 + 196884q + \cdots$ with $q = e^{2\pi i\tau}$.

Proof. (i) Given a lattice, choose an oriented basis (swap ω_1, ω_2 if necessary); then $\omega_1^{-1}\Lambda = \Lambda_\tau$ with $\tau = \omega_2/\omega_1 \in \mathcal{H}$. If $\Lambda_{\tau'} = c\Lambda_\tau$, then $(c, c\tau)$ and $(1, \tau')$ are two oriented bases of $\Lambda_{\tau'}$ (as $\mathrm{Im}(c\tau/c) = \mathrm{Im}\,\tau > 0$), so $c\tau = a\tau' + b$, $c = c'\tau' + d$ with $\left(\begin{smallmatrix} a & b \\ c' & d \end{smallmatrix}\right) \in \mathrm{GL}_2(\mathbb{Z})$; then $\tau = \frac{a\tau'+b}{c'\tau'+d}$, and $\mathrm{Im}\,\tau = (ad - bc')\,\mathrm{Im}\,\tau'/|c'\tau' + d|^2$ forces $ad - bc' = +1$; the inverse matrix expresses τ' in terms of τ. Conversely $\Lambda_{\gamma\tau} = (c\tau + d)^{-1}\Lambda_\tau$ for $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$. The bijection with curves is Theorem 9.53 and Proposition 9.55(i). (ii) $G_{2k}(\Lambda_\tau) = \sum_{(m,n)\neq(0,0)} (m + n\tau)^{-2k}$ converges uniformly on compact subsets of $\mathcal{H}$ (the bound of Lemma 9.51 is locally uniform in τ), so it is holomorphic (Appendix A); $\Delta(\Lambda_\tau) \neq 0$, so j is holomorphic, and invariant by (i) and Lemma 9.51. For $\tau = i$, $i\Lambda_i = \Lambda_i$, so $G_6 = i^{-6}G_6 = -G_6$, $g_3 = 0$ and $j = 1728$; for $\tau = \zeta_3 = e^{2\pi i/3}$, $\zeta_3\Lambda = \Lambda$, so $G_4 = \zeta_3^{-4}G_4$, $g_2 = 0$ and $j = 0$. (iii) We do not prove this here; it is proved in Chapter 12 (fundamental domain, valence formula, q-expansions). Injectivity also follows from (i) and Theorem 9.6(i), surjectivity from Theorem 9.6(ii) and Theorem 9.53(ii). □

Definition 9.57 (the period lattice of a curve over $\mathbb{Q}$)**.** Let $E/\mathbb{Q}$ be given by its global minimal model (Chapter 10) and $\omega = dx/(2y + a_1x + a_3)$ its Néron differential. The *period lattice* of E is $\Lambda_E = \{\int_\gamma \omega : \gamma \in H_1(E(\mathbb{C}), \mathbb{Z})\}$, so that $E(\mathbb{C}) \simeq \mathbb{C}/\Lambda_E$ with $\omega \leftrightarrow dz$ (Theorem 9.53(ii)). Its *area* is $\mathrm{vol}(\Lambda_E)$, and $\omega_1(E)$ is the least positive real element of Λ_E (the *real period*).

Proposition 9.58 (periods of curves over $\mathbb{Q}$)**.** *Let $E/\mathbb{Q}$ be as in Definition 9.57.*

(i) Λ_E is stable under complex conjugation. If $\Delta > 0$, $\Lambda_E = \mathbb{Z}\omega_1 + \mathbb{Z}\omega_2$ with $\omega_1 > 0$ and $\omega_2 \in i\mathbb{R}$ (a rectangular lattice; $E(\mathbb{R})$ has two components). If $\Delta < 0$, $\Lambda_E = \mathbb{Z}\omega_1 + \mathbb{Z}\omega_2$ with $\omega_1 > 0$ and $\mathrm{Re}\,\omega_2 = \omega_1/2$ ($E(\mathbb{R})$ is connected).

(ii) $\mathrm{vol}(\Lambda_E) = \omega_1\,\mathrm{Im}\,\omega_2$ for such a basis with $\mathrm{Im}\,\omega_2 > 0$, and $\mathrm{vol}(\Lambda_E) = \frac{i}{2}\int_{E(\mathbb{C})} \omega \wedge \bar{\omega}$.

(iii) The periods are computed by the arithmetic-geometric mean $\mathrm{AGM}(a, b)$, the common limit of $a_{n+1} = (a_n + b_n)/2$, $b_{n+1} = \sqrt{a_n b_n}$ for $a_0 = a > 0$, $b_0 = b > 0$. If $\Delta < 0$, let e_1 be the real root of $F(x) = 4x^3 + b_2x^2 + 2b_4x + b_6$, $\gamma = 3e_1 + b_2/4$ and $\delta = \sqrt{3e_1^2 + b_2e_1/2 + b_4/2}$; then

$$\omega_1 = \frac{2\pi}{\mathrm{AGM}(2\sqrt{\delta}, \sqrt{2\delta + \gamma})}, \qquad \mathrm{Im}\,\omega_2 = \frac{\pi}{\mathrm{AGM}(2\sqrt{\delta}, \sqrt{2\delta - \gamma})}$$

for the basis of (i) with $\mathrm{Im}\,\omega_2 > 0$ [30, Section 7.4], [35, Section 3.7]. In PARI the periods are `E.omega`.

(iv) If $\varphi\colon E \to E'$ is an isogeny over $\mathbb{Q}$ and ω' is the Néron differential of E', then $\varphi^*\omega' = c_\varphi\,\omega$ with $c_\varphi \in \mathbb{Q}^\times$, and $z \mapsto c_\varphi z$ maps Λ_E into $\Lambda_{E'}$; so the period lattices of isogenous curves are commensurable.

Sketch of proof. (i) Complex conjugation acts on $E(\mathbb{C})$ and on $H_1(E(\mathbb{C}),\mathbb{Z})$, and $\int_{\bar\gamma}\omega = \overline{\int_\gamma \omega}$ because ω has real coefficients; so $\bar\Lambda_E = \Lambda_E$. For a conjugation-stable lattice, $\Lambda \cap \mathbb{R} = \mathbb{Z}\omega_1$ and $\Lambda \cap i\mathbb{R} = \mathbb{Z}i\mu$ with $\omega_1, \mu > 0$, and $2\lambda = (\lambda + \bar\lambda) + (\lambda - \bar\lambda) \in \mathbb{Z}\omega_1 + \mathbb{Z}i\mu$ for every $\lambda \in \Lambda$, so Λ contains $\mathbb{Z}\omega_1 + \mathbb{Z}i\mu$ with index 1 or 2: rectangular, or with basis ω_1, $\frac{\omega_1}{2} + \frac{i\mu}{2}$. Which case occurs is decided by the number of real roots of F, that is, by the sign of Δ [35, Section 3.7]. (ii) The area of the parallelogram; and $\frac{i}{2}dz \wedge d\bar z = dx \wedge dy$ on $\mathbb{C}$. (iii) We do not prove the AGM formula; see the references given, and Exercise 9.114 for the numbers of `11a1`. (iv) $\varphi^*\omega'$ is a holomorphic differential defined over $\mathbb{Q}$, hence a rational multiple of ω, nonzero because φ is separable; under the uniformisations φ becomes $z \mapsto c_\varphi z$ (Proposition 9.55(i)). For a modular parametrisation in place of φ the analogous constant is the subject of the Manin constant (Chapter 14). □

Example 9.59 (the periods of `11a1`)**.** For `11a1`, $\Delta = -11^5 < 0$, and PARI gives (to 20 digits)

$$\omega_1 = 1.2692093042795534217\ldots,$$

$$\omega_2 = \tfrac{1}{2}\omega_1 + 1.4588166169384952294\ldots\, i,$$

so that

$$\operatorname{vol}(\Lambda_E) = \omega_1 \operatorname{Im}\omega_2 = 1.8515436234559593178\ldots.$$

The value ω_1 agrees with the column $\Omega = 1.26920930427955$ of Cremona's `allbsd` file. The point $\tau = \omega_2/\omega_1 = \frac{1}{2} + 1.1493901061232523807\ldots\, i$ is equivalent under $\tau \mapsto \tau - 1$ to $-\frac{1}{2} + 1.14939\ldots\, i$, which lies in the standard fundamental domain $|\operatorname{Re}\tau| \le \frac{1}{2}$, $|\tau| \ge 1$, and $j(\tau) = -757.672637860056752\ldots = -122023936/161051 = j(\texttt{11a1})$ to 18 significant digits, the precision to which τ is given. (PARI returns the basis $(\omega_1, \frac{1}{2}\omega_1 - 1.4588\ldots i)$, which is not oriented.) The area enters the formula $\deg\varphi_E = 4\pi^2 c_E^2\langle f, f\rangle / \operatorname{vol}(\Lambda_E)$ of Chapter 14, where for `11a1` the modular degree is 1.

9.8 Elliptic curves over finite fields

The numbers a_q of the paper are point counts over finite fields, and its local factors at good primes and at the type I_0^* primes are built from the roots α, β of $X^2 - a_q X + q$. This section proves the Hasse bound, the characteristic polynomial of Frobenius on the Tate module, and the identity $(\mathfrak{q}+1)^2 - a^2 = \#E(\mathbb{F}_\mathfrak{q}) \cdot \#E^{\mathrm{tw}}(\mathbb{F}_\mathfrak{q})$ behind the type I_0^* row of the paper's table, and it connects a_p with $\rho_{E,\ell}(\mathrm{Frob}_p)$ for a curve over $\mathbb{Q}$ with good reduction at p.

Definition 9.60 (the Frobenius endomorphism and $a_\mathfrak{q}$)**.** Let E be an elliptic curve over $\mathbb{F}_\mathfrak{q}$, $\mathfrak{q} = p^r$. The *Frobenius endomorphism* is $\pi = \pi_\mathfrak{q}\colon (x, y) \mapsto (x^\mathfrak{q}, y^\mathfrak{q})$, and

$$a_\mathfrak{q} = a_\mathfrak{q}(E) = \mathfrak{q} + 1 - \#E(\mathbb{F}_\mathfrak{q}).$$

Proposition 9.61 (properties of π)**.**

(i) π is an endomorphism of E of degree $\mathfrak{q}$, purely inseparable, and it acts on $E(\overline{\mathbb{F}}_p)$ as the arithmetic Frobenius $\mathrm{Frob}_\mathfrak{q}$.

(ii) $E(\mathbb{F}_{\mathfrak{q}^n}) = \ker(1-\pi^n)$ *for* $n \geq 1$.

(iii) $1-\pi$ *is separable, so* $\#E(\mathbb{F}_{\mathfrak{q}}) = \deg(1-\pi)$.

Proof. (i) π maps E to itself because the coefficients of E lie in $\mathbb{F}_{\mathfrak{q}}$ and are fixed by $t \mapsto t^{\mathfrak{q}}$; it fixes O. Its degree, inseparability and its action on points are Chapter 8 (the Frobenius morphism). (ii) A point of $E(\overline{\mathbb{F}}_p)$ is fixed by π^n iff its coordinates are fixed by $t \mapsto t^{\mathfrak{q}^n}$, iff they lie in $\mathbb{F}_{\mathfrak{q}^n}$. (iii) $\pi^*(dx) = d(x^{\mathfrak{q}}) = \mathfrak{q}x^{\mathfrak{q}-1}dx = 0$, so $\pi^*\omega = 0$ and, by Proposition 9.15(iii), $(1-\pi)^*\omega = \omega \neq 0$; so $1-\pi$ is separable (Chapter 8) and $\#\ker(1-\pi) = \deg(1-\pi)$ (Theorem 9.19(iii)). □

Theorem 9.62 (Hasse)**.** $|a_{\mathfrak{q}}| \leq 2\sqrt{\mathfrak{q}}$.

Proof. By Theorem 9.21(iv) the pairing $\langle \varphi, \psi \rangle = \deg(\varphi+\psi) - \deg\varphi - \deg\psi$ is bilinear on $\mathrm{End}(E)$. Taking $\varphi = 1$, $\psi = -\pi$, and using $\deg(-\pi) = \deg\pi = \mathfrak{q}$ (Proposition 9.61(i)) and $\langle 1, -\pi\rangle = -\langle 1, \pi\rangle$, one gets $\deg(1-\pi) = 1 + \mathfrak{q} - \langle 1, \pi\rangle$, so $\langle 1, \pi\rangle = 1 + \mathfrak{q} - \#E(\mathbb{F}_{\mathfrak{q}}) = a_{\mathfrak{q}}$ by Proposition 9.61(iii). For $m, n \in \mathbb{Z}$, expanding in the same way,

$$0 \leq \deg(m - n\pi) = m^2 \deg 1 + n^2 \deg\pi - mn\langle 1, \pi\rangle = m^2 - a_{\mathfrak{q}}mn + \mathfrak{q}n^2.$$

A binary quadratic form that is nonnegative on $\mathbb{Z}^2$ is nonnegative on $\mathbb{Q}^2$ (by homogeneity) and on $\mathbb{R}^2$ (by continuity). Taking $(m, n) = (a_{\mathfrak{q}}/2, 1)$ gives $\mathfrak{q} - a_{\mathfrak{q}}^2/4 \geq 0$, that is, $a_{\mathfrak{q}}^2 \leq 4\mathfrak{q}$. □

Theorem 9.63 (the characteristic polynomial of Frobenius)**.** *Let* $\ell \neq p$.

(i) For every $\varphi \in \mathrm{End}(E)$*, the induced endomorphism* φ_ℓ *of* $T_\ell E$ *has* $\det\varphi_\ell = \deg\varphi$ *and* $\operatorname{tr}\varphi_\ell = 1 + \deg\varphi - \deg(1-\varphi)$*; both lie in* $\mathbb{Z}$.

(ii) π_ℓ *has characteristic polynomial* $X^2 - a_{\mathfrak{q}}X + \mathfrak{q}$*, and* $\pi^2 - a_{\mathfrak{q}}\pi + \mathfrak{q} = 0$ *in* $\mathrm{End}(E)$.

(iii) Let $\alpha, \beta \in \mathbb{C}$ *be the roots of* $X^2 - a_{\mathfrak{q}}X + \mathfrak{q}$*. Then* $\alpha + \beta = a_{\mathfrak{q}}$, $\alpha\beta = \mathfrak{q}$, $|\alpha| = |\beta| = \sqrt{\mathfrak{q}}$*, and for every* $n \geq 1$

$$\#E(\mathbb{F}_{\mathfrak{q}^n}) = \mathfrak{q}^n + 1 - \alpha^n - \beta^n; \quad \textit{in particular} \quad \#E(\mathbb{F}_{\mathfrak{q}^2}) = \mathfrak{q}^2 + 1 - (a_{\mathfrak{q}}^2 - 2\mathfrak{q}).$$

Equivalently, the zeta function of E *is*

$$Z(E/\mathbb{F}_{\mathfrak{q}}, T) = \exp\Big(\sum_{n\geq 1} \#E(\mathbb{F}_{\mathfrak{q}^n})\frac{T^n}{n}\Big) = \frac{1 - a_{\mathfrak{q}}T + \mathfrak{q}T^2}{(1-T)(1-\mathfrak{q}T)}.$$

Proof. (i) The Weil pairing e on $T_\ell E$ (Proposition 9.35(iii)) satisfies $e(\varphi s, \varphi t) = e(s, \hat\varphi\varphi t) = e(s,t)^{\deg\varphi}$ by Theorem 9.32(vi) and Theorem 9.21. For any $\mathbb{Z}_\ell$-linear g on a free module of rank 2 and an alternating bilinear form e, $e(gs, gt) = e(s,t)^{\det g}$ (check on a basis, as in Corollary 9.33). Since e is perfect, some $e(s,t)$ generates $\mathbb{Z}_\ell(1)$, so $\det\varphi_\ell = \deg\varphi$. For a 2×2 matrix g, $\det(1-g) = 1 - \operatorname{tr} g + \det g$, and $(1-\varphi)_\ell = 1 - \varphi_\ell$. (ii) By (i) and Proposition 9.61(iii), $\det\pi_\ell = \deg\pi = \mathfrak{q}$ and $\operatorname{tr}\pi_\ell = 1 + \mathfrak{q} - \#E(\mathbb{F}_{\mathfrak{q}}) = a_{\mathfrak{q}}$. By Cayley-Hamilton, $\pi^2 - a_{\mathfrak{q}}\pi + \mathfrak{q}$ acts as 0 on $T_\ell E$, hence kills every $E[\ell^n]$; a nonzero endomorphism has finite kernel (Theorem 9.19(ii)), so it is 0. (iii) The discriminant $a_{\mathfrak{q}}^2 - 4\mathfrak{q} \leq 0$ (Theorem 9.62), so α, β are complex conjugate, and $\alpha\beta = \mathfrak{q}$ gives $|\alpha|^2 = \mathfrak{q}$. As π^n is the Frobenius of $\mathbb{F}_{\mathfrak{q}^n}$, $\#E(\mathbb{F}_{\mathfrak{q}^n}) = \deg(1-\pi^n) = \det(1-\pi_\ell^n) = (1-\alpha^n)(1-\beta^n)$, the eigenvalues of π_ℓ^n being α^n, β^n. For $n = 2$, $\alpha^2 + \beta^2 = a_{\mathfrak{q}}^2 - 2\mathfrak{q}$. Finally $\sum_n (1 + \mathfrak{q}^n - \alpha^n - \beta^n)T^n/n = -\log(1-T) - \log(1-\mathfrak{q}T) + \log(1-\alpha T) + \log(1-\beta T)$. □

For `11a1`, with $a_3=-1$, $a_5=1$, $a_7=-2$, $a_{13}=4$, the formula gives $\#E(\mathbb{F}_{p^2})=15,35,60,180$ for $p=3,5,7,13$ (for instance $9+1-((-1)^2-6)=15$ and $49+1-(4-14)=60$), and a direct count over $\mathbb{F}_{p^2}$ with PARI gives the same numbers.

Definition 9.64 (supersingular and ordinary)**.** An elliptic curve E over $\mathbb{F}_{\mathfrak{q}}$ is *supersingular* if $E[p]=0$, and *ordinary* otherwise.

Proposition 9.65 (criteria for supersingularity)**.**

(i) E is supersingular iff $p \mid a_{\mathfrak{q}}$, iff $\mathrm{End}_{\overline{\mathbb{F}}_p}(E)$ is an order in a quaternion algebra.

(ii) If $\mathfrak{q}=p\geq 5$, then E is supersingular iff $a_p=0$.

Proof. (i) We do not prove this; see [185, Section V.3]. (ii) By (i) supersingularity means $p \mid a_p$, and $|a_p|\leq 2\sqrt{p}<p$ for $p\geq 5$ (Theorem 9.62), so $p \mid a_p$ iff $a_p=0$. □

For example, by (i) the reduction of `11a1` is supersingular at $p=19$ and $p=29$, where $a_p=0$, and also at $p=2$, where $a_2=-2$ is divisible by 2 (Example 9.68); it is ordinary at the other good primes $p<40$ (PARI's `ellissupersingular` agrees). The case $p=2$ shows why (ii) needs $p\geq 5$: for $p=2,3$ one has $2\sqrt{p}\geq p$, so $a_p=\pm p$ is allowed by the Hasse bound.

Proposition 9.66 (point counts of a quadratic twist over $\mathbb{F}_{\mathfrak{q}}$)**.** *Let $\mathfrak{q}$ be odd, $E\colon y^2=f(x)$ with f a cubic over $\mathbb{F}_{\mathfrak{q}}$ with distinct roots (so that E is smooth), $\theta\in\mathbb{F}_{\mathfrak{q}}^{\times}$ a non-square, and $E^{\mathrm{tw}}\colon \theta y^2=f(x)$, which is isomorphic to $y^2=\theta^3 f(x/\theta)$, the twist of E by θ in the sense of Definition 9.83. Let η be the quadratic character of $\mathbb{F}_{\mathfrak{q}}^{\times}$, extended by $\eta(0)=0$. Then*

$$\#E(\mathbb{F}_{\mathfrak{q}})=\mathfrak{q}+1+\sum_{x\in\mathbb{F}_{\mathfrak{q}}}\eta(f(x)),\qquad a_{\mathfrak{q}}(E^{\mathrm{tw}})=-a_{\mathfrak{q}}(E),\qquad \#E(\mathbb{F}_{\mathfrak{q}})+\#E^{\mathrm{tw}}(\mathbb{F}_{\mathfrak{q}})=2\mathfrak{q}+2,$$

$$(\mathfrak{q}+1)^2-a_{\mathfrak{q}}(E)^2=\#E(\mathbb{F}_{\mathfrak{q}})\cdot\#E^{\mathrm{tw}}(\mathbb{F}_{\mathfrak{q}}).$$

Proof. For each x, the number of $y\in\mathbb{F}_{\mathfrak{q}}$ with $y^2=c$ is $1+\eta(c)$, and with $\theta y^2=c$ it is $1+\eta(c/\theta)=1-\eta(c)$. Adding the point O, $\#E(\mathbb{F}_{\mathfrak{q}})=1+\sum_x(1+\eta(f(x)))$ and $\#E^{\mathrm{tw}}(\mathbb{F}_{\mathfrak{q}})=1+\sum_x(1-\eta(f(x)))$. So $a_{\mathfrak{q}}(E)=-\sum_x\eta(f(x))=-a_{\mathfrak{q}}(E^{\mathrm{tw}})$, the sum of the two counts is $2\mathfrak{q}+2$, and their product is $(\mathfrak{q}+1-a_{\mathfrak{q}})(\mathfrak{q}+1+a_{\mathfrak{q}})$. The isomorphism: multiplying $\theta y^2=f(x)$ by θ^3 and putting $Y=\theta^2 y$, $X=\theta x$ gives $Y^2=\theta^3 f(X/\theta)$. □

Theorem 9.67 (Frobenius at a prime of good reduction)**.** *Let $E/\mathbb{Q}$ have good reduction at p (its minimal model has $p\nmid\Delta$), let $\tilde{E}$ be the reduction, $a_p=a_p(E)=p+1-\#\tilde{E}(\mathbb{F}_p)$, and $\ell\neq p$.*

(i) $\rho_{E,\ell}$ is unramified at p, and $\rho_{E,\ell}(\mathrm{Frob}_p)$ has characteristic polynomial X^2-a_pX+p, for every choice of arithmetic Frobenius Frob_p; in particular $\operatorname{tr}\rho_{E,\ell}(\mathrm{Frob}_p)=a_p$ does not depend on ℓ.

(ii) $\bar{\rho}_{E,\ell}(\mathrm{Frob}_p)$ has characteristic polynomial X^2-a_pX+p modulo ℓ, so $\operatorname{tr}\bar{\rho}_{E,\ell}(\mathrm{Frob}_p)\equiv a_p \pmod{\ell}$ and $\det\bar{\rho}_{E,\ell}(\mathrm{Frob}_p)\equiv p \pmod{\ell}$.

We write α_p, β_p for the roots of X^2-a_pX+p.

Sketch of proof. Fix an embedding $\overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_p$; it defines a decomposition group $D_p \simeq G_{\mathbb{Q}_p}$ and its inertia group I_p (Chapters 6 and 7). The points of $E[\ell^n]$ have coordinates in the finite extension $L = \mathbb{Q}_p(E[\ell^n])$ of $\mathbb{Q}_p$ inside $\overline{\mathbb{Q}}_p$, and reduction modulo the maximal ideal of the valuation ring of L (equivalently of $\overline{\mathbb{Q}}_p$, with residue field $\bar{\mathbb{F}}_p$) maps $E[\ell^n]$ injectively into $\tilde{E}[\ell^n]$ (Chapter 10: the kernel of reduction has no torsion prime to p); both have ℓ^{2n} elements (Corollary 9.22(ii)), so it is a bijection, equivariant for $D_p \to G_{\mathbb{F}_p}$. Hence I_p acts trivially on $E[\ell^n]$, and Frob_p acts as $\mathrm{Frob}_p \in G_{\mathbb{F}_p}$ does on $\tilde{E}[\ell^n]$, that is, as π (Proposition 9.61(i)). By Theorem 9.63(ii) the characteristic polynomial is $X^2 - a_p X + p$. Part (ii) is the reduction of (i). This is the easy half of the criterion of Néron, Ogg and Shafarevich (Chapter 11); see [185, Section VII.7]. □

Example 9.68 (the numbers a_p for the running examples)**.** Point counts on the global minimal models, $p < 40$; at a bad prime $a_p = p + 1 - \#\tilde{E}(\mathbb{F}_p)$ counting the singular point, which gives 1, -1 or 0 for split multiplicative, nonsplit multiplicative and additive reduction (Chapter 10).

curve	a_2	a_3	a_5	a_7	a_{11}	a_{13}	a_{17}	a_{19}	a_{23}	a_{29}	a_{31}	a_{37}
`11a1`	-2	-1	1	-2	1	4	-2	0	-1	0	7	3
`20a1`	0	-2	-1	2	0	2	-6	-4	6	6	-4	2
`99a1`	-1	0	-4	-2	-1	-2	2	-6	4	-6	4	-6
`121a1`	-1	2	1	2	0	-1	5	-6	2	-9	-2	-3
`121d1`	2	-1	1	2	0	-4	2	0	-1	0	7	3
`539c1`	1	-2	2	0	1	-4	-4	0	-4	-6	-10	-6
`726a1`	-1	-1	0	0	0	-6	6	-6	6	-6	4	-2
`980i1`	0	-3	1	0	-5	3	1	-6	6	-9	4	2

Two patterns can be read off. For `726a1`, whose mod 3 image is $N_s(\mathbb{F}_3)$ and so satisfies $\bar{\rho} \simeq \bar{\rho} \otimes \chi_{-3}$, $a_p \equiv 0 \pmod 3$ at the good $p \equiv 2 \pmod 3$ ($a_5 = 0$, $a_{17} = 6$, $a_{23} = 6$, $a_{29} = -6$), by Theorem 9.67(ii) and $\chi_{-3}(\mathrm{Frob}_p) = -1$. For `11a1`, $a_p \equiv 1 + p \pmod 5$ at every good p (Proposition 9.77). The row of `121d1` is $\chi_{-11}(p)$ times that of `11a1` for $p \neq 11$ (Corollary 9.87). The coefficients of `11a1` agree with those of $q\prod_{n\geq 1}(1-q^n)^2(1-q^{11n})^2$, $q = e^{2\pi i\tau}$, up to q^{20} (Chapter 12).

In the paper 9.69. In the table of Section 1 and in Lemma lem:euler, E' is the twist of good reduction at a type I_0^* prime q, and α, β are the roots of $X^2 - a_q(E')X + q$; the proof uses "$\alpha\beta = q$ and $\alpha + \beta = a_q(E')$" (Theorem 9.63(iii)), and that $\mathrm{ad}^0 V$ has the Frobenius eigenvalues $\alpha/\beta, 1, \beta/\alpha$ for either Frobenius (Convention 9.40(d)). By Proposition 9.66, the factor $(q+1)^2 - a_q(E')^2$ of $e_\ell(E, q)$ is $\#E'(\mathbb{F}_q) \cdot \#E'^{\mathrm{tw}}(\mathbb{F}_q)$, the product of the numbers of points of the reduction of E' and of its unramified quadratic twist; so $v_\ell((q+1)^2 - a_q(E')^2)$ is the sum of the ℓ-adic valuations of two point counts. Lemma lem:old uses that the characteristic polynomial of $\bar{\rho}_h(\mathrm{Frob}_p)$ is $X^2 - a_p(h)X + p$, the analogue of Theorem 9.67(ii) for a newform h (Chapter 15).

With Theorem 9.67 the local information at the good primes is complete: $\rho_{E,\ell}$ is unramified there and its Frobenius traces are the point counts a_p. The next section turns to global questions over $\mathbb{Q}$, where the same representations, now reduced modulo ℓ, decide whether E has rational torsion or rational isogenies.

9.9 Elliptic curves over the rationals: Mordell-Weil, torsion, isogenies

The paper's Eisenstein case (Conjecture conj:eis, Section sec:eis, Proposition prop:no9) is about rational torsion points and rational isogenies, and its remarks on optimality (Section 1, Section sec:oot) are about isogeny classes. This section states the theorems of Mordell and Weil, of Mazur and of Kenku, proves that $E[\ell]$ is reducible exactly when E has a rational ℓ-isogeny, describes the case $E[\ell] \simeq \mathbb{Z}/\ell \oplus \mu_\ell$, proves the paper's Proposition prop:no9, and proves that when $E[\ell]$ is irreducible nothing ℓ-adic depends on which curve of the isogeny class one chooses.

Theorem 9.70 (Mordell, Weil)**.** *For $E/\mathbb{Q}$, the group $E(\mathbb{Q})$ is finitely generated: $E(\mathbb{Q}) \simeq \mathbb{Z}^r \oplus E(\mathbb{Q})_{\mathrm{tors}}$ with $E(\mathbb{Q})_{\mathrm{tors}}$ finite. The integer r is the* rank *of E.*

We do not prove this; see [185, Chapter VIII]. The proof has two halves: the weak Mordell-Weil theorem, that $E(\mathbb{Q})/2E(\mathbb{Q})$ is finite, which comes from the Kummer map into a Selmer group (Chapter 17); and a descent with the canonical height, which is a quadratic form on $E(\mathbb{Q})$ with finitely many points below any bound.

Proposition 9.71 (torsion and reduction)**.** *Let $E/\mathbb{Q}$ be given by its minimal model and p a prime of good reduction.*

(i) Reduction modulo p is injective on $E(\mathbb{Q})[m]$ for every m prime to p, and, if $p \geq 3$, on all of $E(\mathbb{Q})_{\mathrm{tors}}$. Hence $\#E(\mathbb{Q})_{\mathrm{tors}}$ divides $\#\tilde{E}(\mathbb{F}_p)$ for every good prime $p \geq 3$.

(ii) (Nagell and Lutz.) A torsion point of a model with integral coefficients and $a_1 = a_3 = 0$ has integral coordinates.

(iii) For `11a1`, $E(\mathbb{Q})_{\mathrm{tors}} = \langle (5,5) \rangle \simeq \mathbb{Z}/5$; for `20a1`, $E(\mathbb{Q})_{\mathrm{tors}} = \langle (4,10) \rangle \simeq \mathbb{Z}/6$.

Proof. (i) is Chapter 10 (the kernel of reduction is the formal group, which has no torsion prime to p, and no p-torsion for $p \geq 3$ over $\mathbb{Z}_p$); see [185, Sections VII.3 and VIII.7]. (ii) We do not prove this; see [185, Section VIII.7]. (iii) For `11a1`, $\#\tilde{E}(\mathbb{F}_3) = 5$ and $\#\tilde{E}(\mathbb{F}_7) = 10$ (from $a_3 = -1$, $a_7 = -2$, Example 9.68), so $\#E(\mathbb{Q})_{\mathrm{tors}}$ divides 5, and $(5,5)$ has order 5 (Example 9.16). For `20a1`, $\#\tilde{E}(\mathbb{F}_3) = 6$ and $\#\tilde{E}(\mathbb{F}_7) = 6$, so the torsion has order dividing 6, and $(4,10)$ has order 6. □

Theorem 9.72 (Mazur)**.** *For $E/\mathbb{Q}$, $E(\mathbb{Q})_{\mathrm{tors}}$ is isomorphic to one of*

$$\mathbb{Z}/n \ (1 \leq n \leq 10 \text{ or } n = 12), \qquad \mathbb{Z}/2 \times \mathbb{Z}/2n \ (1 \leq n \leq 4),$$

and each of these fifteen groups occurs for infinitely many j-invariants.

We do not prove this; see [125] and [185, Section VIII.7]. In Cremona's tables for conductor below 10,000 the torsion orders that occur are $1, \ldots, 10$, 12 and 16 (the last only as $\mathbb{Z}/2 \times \mathbb{Z}/8$). Consequences used by the paper: $v_\ell(\#E(\mathbb{Q})_{\mathrm{tors}}) \leq 1$ for $\ell = 5, 7$, $E(\mathbb{Q})$ has no point of order $\ell \geq 11$, and $v_3(\#E(\mathbb{Q})_{\mathrm{tors}}) \leq 2$ with equality only for $\mathbb{Z}/9$.

Definition 9.73 (isogeny classes)**.** Curves E, E' over $\mathbb{Q}$ are *isogenous* if there is a nonconstant isogeny $E \to E'$ defined over $\mathbb{Q}$. The equivalence classes (Theorem 9.74(i)) are the *isogeny classes*, labelled by Cremona as N followed by a letter code (Section 9.12). Cremona's *isogeny matrix* of a class lists, for each pair of curves, the least degree of a cyclic isogeny over $\mathbb{Q}$ between them.

Theorem 9.74 (isogeny classes)**.**

(i) Being isogenous over $\mathbb{Q}$ is an equivalence relation.

(ii) Isogenous curves E, E' have $V_\ell E \simeq V_\ell E'$ for every ℓ; hence the same a_p at every prime of good reduction for both, the same L-function (Section 9.11), and the same rank. They have the same conductor. In general they have different torsion, discriminants, j-invariants, Tamagawa numbers and periods.

(iii) (Faltings.) Conversely, E and E' are isogenous over $\mathbb{Q}$ iff $a_p(E) = a_p(E')$ for almost all p, iff $V_\ell E \simeq V_\ell E'$ as $G_{\mathbb{Q}}$-modules for one ℓ.

(iv) (Kenku.) An isogeny class over $\mathbb{Q}$ has at most 8 curves (up to isomorphism over $\mathbb{Q}$).

Proof. (i) Reflexive by [1], transitive by composition, symmetric by the dual isogeny, defined over $\mathbb{Q}$ (Theorem 9.21). (ii) $V_\ell E \simeq V_\ell E'$ is Proposition 9.37(iii); traces of Frobenius give the a_p (Theorem 9.67). For the rank: $\varphi\colon E(\mathbb{Q}) \to E'(\mathbb{Q})$ and $\hat\varphi$ compose to $[\deg\varphi]$, which has finite kernel, so $\operatorname{rank} E(\mathbb{Q}) \le \operatorname{rank} E'(\mathbb{Q})$, and symmetrically. The conductor depends only on $V_\ell E$ as a representation of the local Galois groups (Chapters 10 and 11); we do not prove this here. The examples of Section 9.12 show the differences. (iii) We do not prove this; see [63]. (iv) We do not prove this; see [96, Theorem 2]. □

Examples (Cremona's `allisog` file; rows and columns ordered by curve number): `11a` has matrix $\left(\begin{smallmatrix} 1 & 5 & 5 \\ 5 & 1 & 25 \\ 5 & 25 & 1 \end{smallmatrix}\right)$; `20a` has $\left(\begin{smallmatrix} 1 & 2 & 3 & 6 \\ 2 & 1 & 6 & 3 \\ 3 & 6 & 1 & 2 \\ 6 & 3 & 2 & 1 \end{smallmatrix}\right)$; `121a` and `121c` consist of two curves joined by an 11-isogeny; `121d` has $\left(\begin{smallmatrix} 1 & 5 & 25 \\ 5 & 1 & 5 \\ 25 & 5 & 1 \end{smallmatrix}\right)$; `99a`, `539c` and `726a` consist of two curves joined by a 2-isogeny; `980i` has one curve. Below conductor 10,000 the classes have $1, 2, 3, 4, 6$ or 8 curves.

Proposition 9.75 (rational ℓ-isogenies and reducibility)**.** *Let ℓ be a prime, $\operatorname{char} K \neq \ell$, and E/K.*

(i) The isogenies of degree ℓ from E defined over K, up to isomorphism of the target, correspond bijectively to the G_K-stable lines of $E[\ell]$, by $\varphi \mapsto \ker\varphi$.

(ii) $E[\ell]$ is reducible as an $\mathbb{F}_\ell[G_K]$-module iff E has a K-rational ℓ-isogeny. A K-rational point of order ℓ spans such a line; the converse fails.

(iii) If $E[\ell]$ is reducible, with G_K acting on a stable line by η_1 and on the quotient by η_2, then $\overline{\rho}^{\mathrm{ss}}_{E,\ell} \simeq \eta_1 \oplus \eta_2$ and $\eta_1\eta_2 = \bar\chi_\ell$.

Proof. (i) An isogeny of degree ℓ is separable, since its inseparable degree is a power of $\operatorname{char} K$ dividing ℓ; so its kernel has order ℓ (Theorem 9.19(iii)) and is a line in $E[\ell]$, G_K-stable if the isogeny is defined over K (Definition 9.17). Conversely a G_K-stable line L gives $E \to E/L$ over K, and two separable isogenies with the same kernel differ by an isomorphism of the targets (Theorem 9.20). (ii) $E[\ell]$ is two-dimensional, so it is reducible iff it has a stable line; a rational point of order ℓ is fixed by G_K, so its span is stable. For $K = \mathbb{Q}$: `11a2` has a rational 5-isogeny (its class is `11a`) and trivial torsion; `539a1` has a rational 3-isogeny (image `3B`) and trivial torsion. (iii) is Corollary 9.33(iii). □

As a check on Proposition 9.75 against the data: for $\ell = 3, 5, 7$ and curve number 1 of every class without CM below conductor 10,000, Cremona's `galrep` file lists a Borel or split Cartan image at ℓ (Chapter 11) exactly when the row of the isogeny matrix contains a degree divisible by ℓ.

Theorem 9.76 (Mazur, Kenku: rational cyclic isogenies)**.** *Let $E/\mathbb{Q}$.*

(i) If E has a rational isogeny of prime degree ℓ, then $\ell \in \{2,3,5,7,11,13,17,19,37,43,67,163\}$.

(ii) If E has a rational cyclic isogeny of degree n, then $n \le 19$ or $n \in \{21,25,27,37,43,67,163\}$.

(iii) The degrees $n = 19, 27, 43, 67, 163$ occur only for curves with complex multiplication. For $n = 27$ the curves have $j = -2^{15}\cdot 3\cdot 5^3$ and CM by the order of discriminant -27.

We do not prove this. Part (i) is Mazur's theorem [126]; (ii) and (iii) combine it with Kenku's determinations of the rational points of $X_0(N)$ for the remaining N [92, 94, 93, 95], and the case $N = 27$, where $X_0(27)$ has genus one, is Ligozat's determination of the rational points of the modular curves of genus one [114]. The complete list (ii) is [96, Theorem 1], which attributes the levels of genus one to Ligozat, Ogg and Joly; Kenku does not discuss complex multiplication, so (iii) is not in that paper. A summary table is in [120] (we have not checked its numbering). In Cremona's tables the cyclic 27-isogeny joins `27a2` and `27a4`, both with $j = -12288000 = -2^{15}\cdot 3\cdot 5^3$ (Theorem 9.46), and the isogeny degrees occurring below conductor 10,000 are 1 to 16, 18, 19, 21, 25, 27, 37, 43 and 67.

Proposition 9.77 (the structure $\mathbb{Z}/\ell \oplus \mu_\ell$)**.** *Let ℓ be odd and let $E/\mathbb{Q}$ have a rational point P_0 of order ℓ.*

(i) In a basis (P_0, Q) of $E[\ell]$, $\bar\rho_{E,\ell} = \left(\begin{smallmatrix} 1 & * \\ 0 & \bar\chi_\ell \end{smallmatrix}\right)$.

(ii) The following are equivalent: the sequence $0 \to \mathbb{Z}/\ell \to E[\ell] \to \mu_\ell \to 0$ of Corollary 9.33(iii) splits; $E[\ell] \simeq \mathbb{Z}/\ell \oplus \mu_\ell$ as $G_\mathbb{Q}$-modules; the image of $\bar\rho_{E,\ell}$ is conjugate to $\{\mathrm{diag}(1,d) : d \in \mathbb{F}_\ell^\times\}$ (Sutherland's label ℓ`Cs.1.1`, Chapters 1 and 11); $E[\ell]$ has two $G_\mathbb{Q}$-stable lines, that is, E has two rational ℓ-isogenies, with kernels $\mathbb{Z}/\ell$ and μ_ℓ.

(iii) $a_p \equiv 1 + p \pmod{\ell}$ and $\#\tilde E(\mathbb{F}_p) \equiv 0 \pmod{\ell}$ for every good prime $p \ne \ell$.

Proof. (i) is Corollary 9.33(iii) with $\eta_1 = 1$. (ii) The sequence splits iff there is a stable complement to $\langle P_0\rangle$, iff in a suitable basis the matrices are diagonal, $\mathrm{diag}(1, \bar\chi_\ell(\sigma))$; as $\bar\chi_\ell\colon G_\mathbb{Q} \to \mathbb{F}_\ell^\times$ is surjective, the image is then the whole group $\{\mathrm{diag}(1,d)\}$. A stable complement is a second stable line; since ℓ is odd, $1 \ne \bar\chi_\ell$, the two characters are distinct, and the stable lines are then exactly the two eigenlines, on which $G_\mathbb{Q}$ acts trivially ($\mathbb{Z}/\ell$) and by $\bar\chi_\ell$ (μ_ℓ). Conversely two distinct stable lines give a splitting. Rational ℓ-isogenies correspond to stable lines by Proposition 9.75. (iii) By (i) and Theorem 9.67(ii), $a_p \equiv \mathrm{tr}\left(\begin{smallmatrix} 1 & * \\ 0 & p \end{smallmatrix}\right) = 1 + p$, and $\#\tilde E(\mathbb{F}_p) = p + 1 - a_p \equiv 0$. □

Examples (all checked with PARI and the `galrep` file). The curves `14a1`, `19a1`, `26a1` and the CM curve `27a1` have $E[3] \simeq \mathbb{Z}/3 \oplus \mu_3$ (image `3Cs.1.1`); `20a1` has a rational point of order 3 with non-split $E[3]$ (image `3B.1.1`). The curve `11a1` has $E[5] \simeq \mathbb{Z}/5 \oplus \mu_5$ (image `5Cs.1.1`), and $a_p \equiv 1 + p \pmod 5$ at every good $p < 500$. Its two 5-isogenies have kernels $\mathbb{Z}/5 = \langle(5,5)\rangle$ and μ_5 (the points with x-coordinate a root of $5x^2 + 5x - 29$, a factor of ψ_5); Vélu's formulas give `11a1`$/\langle(5,5)\rangle \simeq$ `11a2`, with trivial torsion, and `11a1`$/\mu_5 \simeq$ `11a3`, which contains the rational group $E[5]/\mu_5 \simeq \mathbb{Z}/5$ and has torsion $\mathbb{Z}/5$.

Proposition 9.78 (no rational point of order 9 beside $\mathbb{Z}/3 \oplus \mu_3$)**.** *Let $E/\mathbb{Q}$ be without complex multiplication, with $E[3] \simeq \mathbb{Z}/3 \oplus \mu_3$. Then $E(\mathbb{Q})$ has no point of order 9; so $E(\mathbb{Q})[3^\infty] \simeq \mathbb{Z}/3$. Consequently, for every $E/\mathbb{Q}$ without complex multiplication,*

$$v_3\big(\#E(\mathbb{Q})_{\mathrm{tors}}\big) + \big[E[3] \simeq \mathbb{Z}/3 \oplus \mu_3\big] \le 2,$$

where $[\cdot]$ *is* 1 *if the condition holds and* 0 *otherwise; and* $v_\ell(\#E(\mathbb{Q})_{\mathrm{tors}}) \le 1$ *for* $\ell = 5, 7$, $= 0$ *for* $\ell \ge 11$.

Proof. Suppose $P \in E(\mathbb{Q})$ has order 9.

Step 1. $3P$ is a rational point of order 3. The rational points of $E[3] \simeq \mathbb{Z}/3 \oplus \mu_3$ are $\mathbb{Z}/3 \oplus \mu_3(\mathbb{Q}) = \mathbb{Z}/3 \oplus 0$, because $\mu_3(\mathbb{Q}) = \{1\}$ ($\chi_{-3} \neq 1$). So $\langle 3P\rangle$ is the line $\mathbb{Z}/3$, and $\langle P\rangle \cap E[3] = \langle 3P\rangle$ (the elements of order dividing 3 in a cyclic group of order 9) meets the line μ_3 only in O.

Step 2. The line μ_3 is $G_{\mathbb{Q}}$-stable, so $\varphi\colon E \to E' = E/\mu_3$ is defined over $\mathbb{Q}$ (Theorem 9.20), of degree 3; let $\hat\varphi\colon E' \to E$ be its dual, also over $\mathbb{Q}$, of degree 3, with $\varphi \circ \hat\varphi = [3]_{E'}$ (Theorem 9.21). For $Q \in E'[3]$, $\varphi(\hat\varphi(Q)) = 3Q = O$, so $\hat\varphi(E'[3]) \subseteq \ker\varphi = \mu_3$. The kernel of $\hat\varphi$ has order 3 and is killed by 3, so it lies in $E'[3]$, and $\#\hat\varphi(E'[3]) = 9/3 = 3$. Hence $\hat\varphi(E'[3]) = \mu_3$.

Step 3. Let $C = \hat\varphi^{-1}(\langle P\rangle) \subset E'(\overline{\mathbb{Q}})$. It is a subgroup, $G_{\mathbb{Q}}$-stable because $\langle P\rangle$ is (it consists of rational points) and $\hat\varphi$ is defined over $\mathbb{Q}$, and $\#C = \#\ker\hat\varphi \cdot \#\langle P\rangle = 27$, because $\hat\varphi$ is surjective on $\overline{\mathbb{Q}}$-points.

Step 4. C is cyclic. If $E'[3] \subseteq C$, then $\mu_3 = \hat\varphi(E'[3]) \subseteq \hat\varphi(C) = \langle P\rangle$, contradicting Step 1. By Proposition 9.23(i), $C \simeq \mathbb{Z}/a \times \mathbb{Z}/ab$ with $a^2 b = 27$ and $E'[a] \subseteq C$; so $a = 1$ and $C \simeq \mathbb{Z}/27$.

Step 5. $E' \to E'/C$ is a rational cyclic isogeny of degree 27 (Theorem 9.20). By Theorem 9.76(iii), E' has complex multiplication, hence so has E (Lemma 9.45): a contradiction.

For the consequences: by Theorem 9.72, $v_3(\#E(\mathbb{Q})_{\mathrm{tors}}) \le 2$ with equality only for $E(\mathbb{Q})_{\mathrm{tors}} \simeq \mathbb{Z}/9$; in that case the bracket is 0 by what was just proved, and otherwise $v_3 \le 1$. The statements for $\ell \ge 5$ are read off Mazur's list. □

Data: the 264 curves of conductor below 10,000 with image `3Cs.1.1` have torsion of order 3 (244 curves) or 6 (20 curves); the six curves there with a rational point of order 9 (`54b3`, `714i1`, `1482l1`, `1554n1`, `1890r3`, `6942n1`) all have image `3B.1.1`.

In the paper 9.79. Proposition 9.78 is the paper's Proposition prop:no9, with every step expanded; it turns the bound "$D \le 2$ for $\ell = 3$" of Conjecture conj:eis into a consequence of the first bound $D \le v_\ell(\#E(\mathbb{Q})_{\mathrm{tors}}) + [E[3] \simeq \mathbb{Z}/3 \oplus \mu_3]$, and gives "$D \le 1$ for $\ell \ge 5$" in the same way. The paper cites [114], Ligozat's study of $X_0(27)$, a curve of genus one, for the fact that a rational cyclic 27-isogeny forces complex multiplication (Theorem 9.76(iii)), and [96, Theorem 1] for the list of the levels N with $Y_0(N)(\mathbb{Q}) \neq \emptyset$, which contains 27; Kenku credits the levels of genus one to Ligozat, Ogg and Joly. In Section sec:eis, "a rational ℓ-isogeny" and "Borel type" refer to Proposition 9.75, and the condition $E[3] \simeq \mathbb{Z}/3 \oplus \mu_3$, which the paper identifies with the image `3Cs.1.1` (the subgroup of order 2 of a split Cartan subgroup fixing a nonzero vector), is Proposition 9.77(ii). The second bound of Conjecture conj:eis counts the curves of the isogeny class with a rational point of order ℓ; in the class `11a` at $\ell = 5$ these are `11a1` and `11a3`.

Lemma 9.80 (isogenies prime to ℓ)**.** *Let* $E/\mathbb{Q}$ *and* ℓ *a prime with* $E[\ell]$ *irreducible.*

(i) Every isogeny $\varphi\colon E \to E'$ *over* $\mathbb{Q}$ *is* $\psi \circ [a]$ *with* $\psi\colon E \to E'$ *a cyclic isogeny over* $\mathbb{Q}$ *of degree prime to* ℓ.

(ii) Hence $T_\ell E \simeq T_\ell E'$ *as* $G_{\mathbb{Q}}$*-modules,* $\rho_{E',\ell}$ *and* $\rho_{E,\ell}$ *are conjugate in* $\mathrm{GL}_2(\mathbb{Z}_\ell)$, $E'[\ell] \simeq E[\ell]$ *is irreducible, and every invariant built from the* $G_{\mathbb{Q}}$*-module* $T_\ell E$ *(the adjoint* $\mathrm{ad}^0 T_\ell E$*, the length* $h_\ell(E)$*, the* ℓ*-adic Tamagawa factors and Selmer groups of* $\mathrm{ad}^0 T_\ell E$*) is the same for* E *and* E'.

(iii) $t_\ell(E, q) = t_\ell(E', q)$ *for every prime* q.

Proof. (i) By Proposition 9.23, $\varphi = \psi \circ [a]$ with ψ cyclic over $\mathbb{Q}$ of some degree n. If $\ell \mid n$, then by Proposition 9.23(iii) E has a rational cyclic ℓ-isogeny, so $E[\ell]$ has a $G_{\mathbb{Q}}$-stable line (Proposition 9.75), contradicting irreducibility. (ii) ψ induces $T_\ell E \simeq T_\ell E'$ by Proposition 9.37(iii), and everything listed is a function of the $G_{\mathbb{Q}}$-module $T_\ell E$ (with its restrictions to decomposition groups). □

Sketch of proof of (iii). $t_\ell(E,q) = v_\ell(-v_q(j_E))$ when $v_q(j_E) < 0$. Over a finite extension of $\mathbb{Q}_q$, E becomes isomorphic to a Tate curve with parameter q_E, $v_q(q_E) = -v_q(j_E)$ (Chapter 10). An isogeny of prime degree r between Tate curves has kernel either μ_r or generated by an r-th root of the parameter, and the parameter of the target is q_E^r, resp. that r-th root; so $v_q(j)$ is multiplied or divided by r. Composing, $v_q(j_{E'}) = v_q(j_E) \cdot r_1^{\pm 1} \cdots r_k^{\pm 1}$ with $r_1 \cdots r_k = \deg \psi$ prime to ℓ, and $v_\ell(-v_q(j))$ is unchanged. (The multiplication map $[a]$ does not change the target.) If $v_q(j_E) \geq 0$ then also $v_q(j_{E'}) \geq 0$, potentially good reduction being an isogeny invariant (Chapter 10). The facts about Tate curves used here are proved in Chapter 10. □

Corollary 9.81 (trivial isogeny classes)**.** *If the isogeny class of $E/\mathbb{Q}$ consists of E alone, then E has no rational ℓ-isogeny for any prime ℓ, so $E[\ell]$ is irreducible for every ℓ (including $\ell = 2$), and E is the $X_0(N)$-optimal curve of its class. Example:* `980i1`*.*

Proof. A rational ℓ-isogeny $E \to E'$ would put E' in the class, and $E' \not\simeq E$ over $\mathbb{Q}$, since an isogeny of degree ℓ from E to a curve isomorphic to E would be an endomorphism of degree ℓ defined over $\mathbb{Q}$, impossible as $\mathrm{End}_{\mathbb{Q}}(E) = \mathbb{Z}$ (Proposition 9.43(ii)) and $\deg[m] = m^2$. Irreducibility follows from Proposition 9.75. The optimal curve is a curve of the class (Chapter 14). □

In the paper 9.82. Section 1 of the paper: "When $E[\ell]$ is irreducible, every curve of the class is linked to E by a cyclic isogeny of degree prime to ℓ" is Lemma 9.80(i); the consequence for the modular degree is Chapter 14. By (ii) and (iii) of the lemma, the hypothesis of Theorem thm:main on $\bar{\rho}_{E,\ell}$, the right-hand side of (eq:identity), and the terms $e_\ell(E,q)$ (read off $V_\ell E$ at q), $t_\ell(E,q)$ and $h_\ell(E)$ of (eq:rule) in Conjecture conj:euler do not depend on which curve of the class is taken. The remaining term $w_3(E)$ of (eq:rule) is defined by the Kodaira type at 3, and Kodaira types are not isogeny invariants in general: `121c1` and `121c2`, joined by an 11-isogeny, have types IV and IV* at 11, and `11a1` and `11a3`, joined by a 5-isogeny, have I_5 and I_1 at 11. In both examples the isogeny has degree equal to the residue characteristic $q = 11$, or the reduction at q is multiplicative. In the situation of (eq:rule) at $\ell = 3$ the type at 3 is an invariant of the class, and the paper proves it (Section sec:data): "when $E[3]$ is irreducible the class has no 3-isogeny, so every isogeny in it is a composite of isogenies of prime degree $p \neq 3$, and an isogeny of prime degree p preserves the Kodaira type at a prime $q \neq p$ of potentially good reduction [56, Theorem 5.4(1)]; so w_3 is constant on the class." The first clause is Lemma 9.80(i) together with the factorisation of a cyclic isogeny into isogenies of prime degree; the theorem of Dokchitser and Dokchitser is applied with $q = 3$. On the tables, below conductor 10,000, among the classes with $3 \mid N$, at least two curves and potentially good reduction at 3, "w_3 is constant on all 1,295 classes without a 3-isogeny, as it must be" (27 of them have complex multiplication, which Conjecture conj:euler excludes). With a 3-isogeny, where (eq:rule) does not apply at $\ell = 3$, the type at 3 can vary: w_3 "varies in 828 of the 1,293 classes with one", for example `54a` with types IV*, II*, II and $w_3 = 2, 2, 1$; Conjecture conj:euler at $\ell = 3$ excludes these classes, as $E[3]$ is then reducible. The conjecture is in any case stated for the optimal curve. Section sec:oot keeps curves "with trivial isogeny class (so that the curve is optimal and $E[\ell]$ is irreducible for every ℓ)": this is Corollary 9.81.

9.10 Quadratic twists

Quadratic twists run through the paper: Lemma lem:twist describes the twist $E^{(q)}$ of E by $\mathbb{Q}(\sqrt{q^*})$, the table of Section 1 and Lemma lem:euler use the twist E' of good reduction at a type I_0^* prime, Theorems thm:twist and thm:quant twist by χ_S, and the Example of Section 3 compares `121a1` with the class `121c`, and `539c1` with `77c1`. This section defines twists for a general Weierstrass model, computes their invariants, proves $\rho_{E^{(d)},\ell} \simeq \rho_{E,\ell} \otimes \chi_d$ and $a_p(E^{(d)}) = \chi_d(p)a_p(E)$, and settles which of the two possible twists the paper means. The effect of twisting on Kodaira types and conductors (Lemma lem:twist (i), (ii)) is proved in Chapter 10.

The idea is simple. The curves $y^2 = f(x)$ and $dy^2 = f(x)$ become isomorphic over $K(\sqrt{d})$, by $y \mapsto y/\sqrt{d}$, but this isomorphism is not defined over K: an automorphism σ with $\sigma(\sqrt{d}) = -\sqrt{d}$ changes it by the automorphism $[-1]$. So the two curves have the same geometry (the same j) but Galois acts on their points differently, through an extra sign $\chi_d(\sigma)$, and every arithmetic quantity built from the Galois action (the a_p, the representation $\rho_{E,\ell}$) is multiplied by χ_d. Over a finite field $\mathbb{F}_p$, with d a non-square, this is the count of Proposition 9.66: an x with $f(x)$ a nonzero square gives two points on one curve and none on the other.

Definition 9.83 (quadratic twists)**.** Let $\operatorname{char} K \neq 2$ and $d \in K^\times$.

(a) For a model $y^2 = x^3 + a_2x^2 + a_4x + a_6$ of E, the *quadratic twist* of E by d (or by $K(\sqrt{d})$, or by χ_d) is
$$E^{(d)}\colon y^2 = x^3 + da_2x^2 + d^2a_4x + d^3a_6,$$
which is isomorphic to $dy^2 = x^3 + a_2x^2 + a_4x + a_6$ by $(x, y) \mapsto (dx, d^2y)$.

(b) For a general model, complete the square first (Lemma 9.3(ii)): from $\eta^2 = 4x^3 + b_2x^2 + 2b_4x + b_6$ one gets $E^{(d)}\colon \eta^2 = 4x^3 + db_2x^2 + 2d^2b_4x + d^3b_6$, and with $X = 4x$, $Y = 4\eta$ the Weierstrass model
$$E^{(d)}\colon Y^2 = X^3 + db_2X^2 + 8d^2b_4X + 16d^3b_6,$$
which has integral coefficients when the a_i and d are integers. For $a_1 = a_3 = 0$ this agrees with (a) (up to the change of coordinates $u = 2$).

(c) For an odd prime q, the paper's $E^{(q)}$ is $E^{(q^*)}$, the twist by $\mathbb{Q}(\sqrt{q^*})$; and for a finite set S of odd primes, $E_S = E^{(d_S)}$ with $d_S = \prod_{q\in S} q^*$ (Definition 9.89).

Proposition 9.84 (first properties of twists)**.** *Let $E\colon y^2 = x^3 + a_2x^2 + a_4x + a_6$ and $d \in K^\times$, $\operatorname{char} K \neq 2$.*

(i) Up to isomorphism over K, $E^{(d)}$ depends only on the class of d in $K^\times/(K^\times)^2$; $E^{(1)} \simeq E$ and $(E^{(d)})^{(d')} \simeq E^{(dd')}$.

(ii) Fix $\sqrt{d} \in \bar{K}$. The map $\psi\colon E^{(d)} \to E$, $(x, y) \mapsto (x/d,\, y/(d\sqrt{d}))$, is an isomorphism defined over $K(\sqrt{d})$, and $\psi^\sigma = [\chi_d(\sigma)] \circ \psi$ for $\sigma \in G_K$, where $\psi^\sigma(P) = \sigma(\psi(\sigma^{-1}P))$. Equivalently $\psi(\sigma P) = \chi_d(\sigma)\,\sigma(\psi(P))$ for $P \in E^{(d)}(\bar{K})$.

(iii) Through ψ, the G_K-set $E^{(d)}(\bar{K})$ is $E(\bar{K})$ with the twisted action *$\sigma * P = \chi_d(\sigma)\sigma(P)$. In particular $E^{(d)}(K) \simeq \{P \in E(K(\sqrt{d})) : \sigma P = -P\}$ for the generator σ of $\mathrm{Gal}(K(\sqrt{d})/K)$ when d is not a square.*

(iv) The twists of E in general (the curves over K isomorphic to E over $\bar{K}$) are classified by $H^1(G_K, \operatorname{Aut}_{\bar{K}} E)$; when $j \neq 0, 1728$, $\operatorname{Aut} E = \{\pm 1\}$ and every twist is quadratic.

Proof. (i) For $d' = du^2$, the change of coordinates $(u, 0, 0, 0)$ of Proposition 9.5 transforms $E^{(du^2)}$ into $E^{(d)}$ (it divides the coefficients of x^2, x, 1 by u^2, u^4, u^6). The other two statements are immediate from the formula. (ii) Substituting $x = dx'$, $y = d\sqrt{d}\,y'$ into the equation of $E^{(d)}$ and dividing by d^3 gives the equation of E in (x', y'); the inverse is $(x', y') \mapsto (dx', d\sqrt{d}y')$. For $\sigma \in G_K$, $\sigma(d\sqrt{d}) = \chi_d(\sigma)d\sqrt{d}$, so $\psi^\sigma(x, y) = (x/d, \chi_d(\sigma)y/(d\sqrt{d}))$, which is $\psi(x, y)$ or $-\psi(x, y) = (x/d, -y/(d\sqrt{d}))$ according as $\chi_d(\sigma) = \pm 1$. (iii) is (ii) restated; a point $P \in E(\bar{K})$ corresponds to a K-point of $E^{(d)}$ iff $\sigma * P = P$ for all σ, i.e. $\sigma P = \chi_d(\sigma)P$. (iv) We do not prove this; see [185, Sections X.2 and X.5]; for the automorphism groups see Proposition 9.7. □

Proposition 9.85 (invariants of twists)**.**

(i) The model of Definition 9.83(a) has $c_4(E^{(d)}) = d^2c_4$, $c_6(E^{(d)}) = d^3c_6$, $\Delta(E^{(d)}) = d^6\Delta$ *and* $j(E^{(d)}) = j(E)$. *The integral model of Definition 9.83(b) has invariants* $2^4d^2c_4$, $2^6d^3c_6$, $2^{12}d^6\Delta$.

(ii) Let $\operatorname{char} K \neq 2, 3$. *If* $j(E) = j(E') \neq 0, 1728$, *then* $E' \simeq E^{(d)}$ *over* K *with* $d = \dfrac{c_6(E')\,c_4(E)}{c_6(E)\,c_4(E')}$, *for any models of* E *and* E'.

(iii) Let q *be an odd prime. If* $q \equiv 1 \pmod 4$ *then* $q = q^*$. *If* $q \equiv 3 \pmod 4$, *the twists of* E *by* q *and by* q^* *differ by the twist by* -1, *which multiplies* c_6 *by* -1, *and they are in general different curves, the twist by* q *being ramified at* 2 *as well. The twist by* q^* *has invariants* $(q^*)^2c_4$, $(q^*)^3c_6$, $(q^*)^6\Delta$; *their* q*-adic valuations are those of* q^2c_4, q^3c_6, $q^6\Delta$.

Proof. (i) For $y^2 = x^3 + Ax^2 + Bx + C$, $b_2 = 4A$, $b_4 = 2B$, $b_6 = 4C$, $b_8 = 4AC - B^2$. Replacing (A, B, C) by (dA, d^2B, d^3C) multiplies b_i by $d^{i/2}$ for $i = 2, 4, 6, 8$; since c_4, c_6, Δ are homogeneous of weights 4, 6, 12 in this grading, they are multiplied by d^2, d^3, d^6, and j is unchanged. For the integral model, the same computation with $(A, B, C) = (db_2, 8d^2b_4, 16d^3b_6)$ gives $2^4d^2c_4$, $2^6d^3c_6$, $2^{12}d^6\Delta$ (checked by machine); this is the change of coordinates with $u = 1/2$ applied to d^2c_4, d^3c_6, $d^6\Delta$. (ii) First, the class of d modulo squares does not depend on the models: a change of coordinates of E' with parameter u replaces (c_4', c_6') by $(u^{-4}c_4', u^{-6}c_6')$ and so multiplies d by u^{-2}, and similarly for E (it multiplies d by u^2); by Proposition 9.84(i) a square factor does not change $E^{(d)}$ up to isomorphism. So we may take short models (Lemma 9.3(iii)), which have invariants 6^4c_4, 6^6c_6 (and likewise for E'); passing to them for both curves does not change the quotient defining d at all. As $j \neq 0, 1728$, $c_4, c_6, c_4', c_6' \neq 0$, and $j = j'$ is equivalent to $c_6^2/c_4^3 = c_6'^2/c_4'^3$. Then $d^2c_4 = c_6'^2c_4^3/(c_6^2c_4'^2) = c_4'$ and $d^3c_6 = d^2c_4 \cdot dc_6/c_4 = c_4' \cdot c_6'/c_4' = c_6'$. By (i), $E^{(d)}$ has the same c_4, c_6 as E', hence the same short model. (iii) $q = -q^*$ when $q \equiv 3 \pmod 4$, and $E^{(-q^*)} \simeq (E^{(q^*)})^{(-1)}$ by Proposition 9.84(i). By (i) the twist by -1 multiplies c_6 by -1; the field $\mathbb{Q}(\sqrt{-1})$ is ramified at 2. The last statement is (i) with $v_q(q^*) = v_q(q) = 1$. □

An example of (ii): `980i1` and `140b1` have the same $j = 2^{19}3^3/(5 \cdot 7^5)$ (Example 9.8), with $(c_4, c_6) = (-75264, 62826624)$ and $(-1536, -183168)$. The recipe gives

$$d = \frac{(-183168)(-75264)}{62826624 \cdot (-1536)} = -\frac{183168 \cdot 49}{62826624} = -\frac{1}{7},$$

using $75264 = 49 \cdot 1536$ and $62826624 = 7 \cdot 8975232 = 7 \cdot 183168 \cdot 49$. So `140b1` $\simeq$ `980i1`$^{(-1/7)} \simeq$ `980i1`$^{(-7)}$, as $-1/7 = -7 \cdot (1/7)^2$; this is the identification used in Warning 9.91(b).

Theorem 9.86 (the Galois representation of a twist)**.** *Let* $\operatorname{char} K \neq 2$, $d \in K^\times$ *and* $\ell \neq \operatorname{char} K$. *Then* ψ *of Proposition 9.84(ii) induces a* G_K*-isomorphism* $T_\ell E^{(d)} \simeq T_\ell E \otimes \chi_d$*; that is,* $\rho_{E^{(d)},\ell} \simeq \rho_{E,\ell} \otimes \chi_d$. *Consequently* $\bar\rho_{E^{(d)},\ell} \simeq \bar\rho_{E,\ell} \otimes \chi_d$, $E^{(d)}[2] \simeq E[2]$, $\det \rho_{E^{(d)},\ell} = \det \rho_{E,\ell}$, $\operatorname{ad}^0 T_\ell E^{(d)} \simeq \operatorname{ad}^0 T_\ell E$, *and* $E^{(d)}[\ell]$ *is irreducible iff* $E[\ell]$ *is.*

Proof. ψ is an isomorphism of groups (Theorem 9.19(i)), so it maps $E^{(d)}[\ell^n]$ bijectively to $E[\ell^n]$, compatibly with $[\ell]$, and by Proposition 9.84(ii) $\psi(\sigma P) = \chi_d(\sigma)\sigma(\psi(P))$. This says that $\psi_\ell \colon T_\ell E^{(d)} \to T_\ell E \otimes \chi_d$ is G_K-equivariant. On $E[2]$, $\chi_d(\sigma) = \pm 1$ acts trivially. Determinants are multiplied by $\chi_d^2 = 1$, and $\operatorname{ad}^0(T \otimes \chi) = \operatorname{ad}^0 T$ (Chapter 4). Twisting by a character preserves the lattice of stable subspaces. □

Corollary 9.87 (a_p of a twist)**.** *Let* $E/\mathbb{Q}$, $d \in \mathbb{Q}^\times$ *not a square,* D *the discriminant of* $\mathbb{Q}(\sqrt{d})$, *and* p *a prime of good reduction for* E *with* $p \nmid D$. *Then* $E^{(d)}$ *has good reduction at* p *and*

$$a_p(E^{(d)}) = \chi_d(p)\, a_p(E), \qquad \chi_d(p) = \Big(\frac{D}{p}\Big).$$

Proof. Good reduction of $E^{(d)}$ at p: E and $E^{(d)}$ become isomorphic over the extension $\mathbb{Q}_p(\sqrt{d})$, unramified at p, and good reduction is invariant under unramified extension (Chapter 10). By Theorem 9.86 and Theorem 9.67, for $\ell \neq p$, $a_p(E^{(d)}) = \operatorname{tr}(\rho_{E,\ell} \otimes \chi_d)(\mathrm{Frob}_p) = \chi_d(\mathrm{Frob}_p) a_p(E)$, and $\chi_d(\mathrm{Frob}_p) = \left(\frac{D}{p}\right)$ (Convention 9.1(d)). An elementary proof when p is odd and $p \nmid d\Delta$: with $E \colon y^2 = f(x)$ and $E^{(d)} \colon y^2 = d^3 f(x/d)$, Proposition 9.66 gives $a_p(E^{(d)}) = -\sum_x \eta(d^3 f(x/d)) = -\eta(d) \sum_{x'} \eta(f(x')) = \eta(d) a_p(E)$: here $\eta(d^3) = \eta(d)^3 = \eta(d)$, and $x' = x/d$ runs over $\mathbb{F}_p$ as x does. Finally $\eta(d) = \left(\frac{d}{p}\right) = \left(\frac{D}{p}\right)$, since d/D is the square of a rational number whose numerator and denominator are prime to p (as $p \nmid dD$). □

Checked for every good $p < 400$, $p = 2$ included where allowed: `121d1` against `11a3`, `121d2` against `11a1` (with χ_{-11}); `121c2` against `121a1` (χ_{-11}); `77c1` against `539c1` and `140b1` against `980i1` (χ_{-7}).

Proposition 9.88 (the twist of good reduction at a type I_0^* prime)**.** *Let* q *be an odd prime at which* $E/\mathbb{Q}$ *has type* I_0^*, *and* $E' = E^{(q^*)}$, *which has good reduction at* q *(Chapter 10).*

(i) $V_\ell E \simeq V_\ell E' \otimes \chi_{q^*}$ *for every* $\ell \neq q$, *with* $V_\ell E'$ *unramified at* q.

(ii) The twists of E *with good reduction at* q *are the curves* $E^{(q^* d)}$ *with* $q \nmid D$, D *the discriminant of* $\mathbb{Q}(\sqrt{d})$*; for them* $a_q(E^{(q^* d)}) = \chi_d(q) a_q(E') = \pm a_q(E')$. *Hence* $a_q(E')^2$, $(q+1)^2 - a_q(E')^2$ *and the set* $\{\alpha/\beta, \beta/\alpha\}$ *for the roots of* $X^2 - a_q(E')X + q$ *depend only on* E *and* q.

(iii) Example: `539d1` *has type* I_0^* *at* 7, *and* `539d1`$^{(-7)} \simeq$ `11a3`, *with* $a_7 = -2$. *So* $(7+1)^2 - a_7^2 = 60$ *and* $e_3($`539d1`$, 7) = v_3(7-1) + v_3(60) = 2 = v_3(72) = v_3(\deg \varphi_E)$ *for* $E =$ `539d1`.

Proof. (i) is Theorem 9.86 (as $\chi_{q^*}^2 = 1$) and Theorem 9.67. (ii) $E^{(q^* d)} = (E')^{(d)}$ (Proposition 9.84(i)). If $q \nmid D$, it has good reduction at q and $a_q = \chi_d(q) a_q(E')$ by Corollary 9.87. If $q \mid D$, it is the twist of the curve E', of good reduction at q, by a character ramified at q, which has type I_0^* (Chapter 10), not good reduction. Replacing $a_q(E')$ by $-a_q(E')$ replaces (α, β) by $(-\alpha, -\beta)$ and does not change α/β. (iii) Computed with PARI: the minimal model of the twist of `539d1` by -7 is $[0, -1, 1, 0, 0]$, which is `11a3`; the modular degree $\deg \varphi_E = 72$ of $E =$ `539d1` is from Cremona's `degphi` file. □

Definition 9.89 (composite twists)**.** For a finite set S of odd primes, $\chi_S = \prod_{q\in S}\chi_{q^*}$ is the quadratic character of $\mathbb{Q}(\sqrt{d_S})$, $d_S = \prod_{q\in S} q^*$, a fundamental discriminant $\equiv 1 \pmod 4$; it has conductor $\prod_{q\in S} q$ and is unramified outside S (Chapters 2 and 6). The twist $E_S = E^{(d_S)}$ is obtained by twisting successively by the q^*, $q \in S$, in any order (Proposition 9.84(i)), $\rho_{E_S,\ell} \simeq \rho_{E,\ell}\otimes\chi_S$, and $a_p(E_S) = \chi_S(p)a_p(E)$ for every good $p \notin S$ (Corollary 9.87).

Remark 9.90 (what a twist changes). Under every quadratic twist the invariants j, $v_q(j)$, hence $t_\ell(E,q)$, and $\mathrm{ad}^0\,\rho_{E,\ell}$ are unchanged (Proposition 9.85(i), Theorem 9.86). The numbers a_q, the discriminant, the Kodaira type at a prime where the twist ramifies, and the naive Euler factor L_q^{nv} change. So $e_\ell(E,q)$, which compares the true adjoint factor (an invariant of $\mathrm{ad}^0\,V$) with the naive one, is invariant under twists unramified at q (which change neither factor, by Chapter 10) but not under twists ramified at q: `11a1` has type I_5 at 11 and $e_3 = 0$, while its twist $\texttt{11a1}^{(-11)} \simeq \texttt{121d2}$ has type I_5^* and $e_3 = v_3(11^2-1) = 1$; likewise `11a3` (I_1) and $\texttt{11a3}^{(-11)} \simeq \texttt{121d1}$ (I_1^*). The types are from Chapter 10.

Warning 9.91 (q versus q^*; curve versus class). (a) For $q \equiv 3 \pmod 4$ the twist by $\mathbb{Q}(\sqrt{q})$ is not the paper's twist. For `121a1`: $\texttt{121a1}^{(-11)} \simeq \texttt{121c2}$, of conductor 121, while $\texttt{121a1}^{(11)} \simeq \texttt{1936k2}$, of conductor $1936 = 2^4\cdot 11^2$. Only q-adic valuations enter Lemma lem:twist (ii), and they agree (Proposition 9.85(iii)). (b) A twist of a curve is a curve, and a twist of a class is a class. With the minimal models of Cremona's tables, as checked with PARI:

$$\texttt{11a1}^{(-11)} \simeq \texttt{121d2},\quad \texttt{11a3}^{(-11)} \simeq \texttt{121d1},\quad \texttt{11a2}^{(-11)} \simeq \texttt{121d3},\quad \texttt{121a1}^{(-11)} \simeq \texttt{121c2},$$

$$\texttt{539c1}^{(-7)} \simeq \texttt{77c1},\quad \texttt{980i1}^{(-7)} \simeq \texttt{140b1},\quad \texttt{11a1}^{(-7)} \simeq \texttt{539d2},$$

$$\texttt{11a3}^{(-7)} \simeq \texttt{539d1},\quad \texttt{20a1}^{(-1)} \simeq \texttt{80b1}.$$

Statements about a_p, L-functions, V_ℓ and (for ℓ prime to the isogeny degrees) T_ℓ are statements about classes; statements about j, Δ, Kodaira types, torsion and $v_q(j)$ are about curves. "The twist of `11a1` by χ_{-11} is in the class `121d`" is right; "it is `121d1`" is not.

In the paper 9.92. The proof of Lemma lem:twist (ii) of the paper: "the twist has a model with invariants $(q^*)^2c_4$, $(q^*)^3c_6$, $(q^*)^6\Delta$ and the same j-invariant" is Proposition 9.85(i), (iii), and its model $y^2 = x^3 + q^*a_2x^2 + (q^*)^2a_4x + (q^*)^3a_6$ is Definition 9.83(a). Lemma lem:euler: in the row I_n^*, "$V = V'\otimes\chi_{q^*}$ with V' Steinberg at q" and "$\mathrm{ad}^0\,V = \mathrm{ad}^0\,V'$" are Theorem 9.86 (the Steinberg property of V' is Chapter 10); in the row I_0^*, "$V = V'\otimes\chi_{q^*}$ with V' unramified" is Proposition 9.88(i). Theorems thm:twist and thm:quant: E_S, χ_S and $a_p(f) = \chi_S(p)a_p(g)$ are Definition 9.89. The table of Section 1: "E' the quadratic twist of E by $\mathbb{Q}(\sqrt{q^*})$" is Proposition 9.88, and (ii) of that proposition is why only $a_q(E')^2$ matters. Definition def:terms: "The term t_ℓ is invariant under quadratic twist, and $e_\ell(E,q)$ under quadratic twists unramified at q" is Remark 9.90. The Example of Section 3 (ex:qual) twists `121a1` and `539c1`, `980i1` by χ_{-11} and χ_{-7}; its identifications are at the level of classes, and Warning 9.91(b) gives the curves.

9.11 The L-function

The paper's newform $f = f_E$ is the modular form whose L-series is $L(E,s)$, and Lemma lem:old uses the multiplicativity of its coefficients and the recursion at good primes. This section defines $L(E,s)$ by its Euler product, including the factors at the bad primes, and proves what follows from the results above. Analytic continuation and the functional equation are Chapter 19, modularity is Chapter 14, and the adjoint L-function is Chapter 19.

Definition 9.93 (the L-function of E)**.** Let $E/\mathbb{Q}$ have conductor N (Chapter 10), given by its global minimal model. For every prime p let $\tilde{E}$ be the reduction modulo p and $a_p = p+1-\#\tilde{E}(\mathbb{F}_p)$, the singular point included when $p \mid N$; so for $p \mid N$, $a_p = 1$, -1 or 0 according as the reduction is split multiplicative, nonsplit multiplicative or additive (Chapter 10). Define

$$L(E,s) = \prod_{p\nmid N} (1 - a_p p^{-s} + p^{1-2s})^{-1} \prod_{p\mid N} (1 - a_p p^{-s})^{-1} = \sum_{n\geq 1} a_n n^{-s}.$$

Proposition 9.94 (properties of $L(E,s)$)**.**

(i) $|a_n| \leq d(n)\sqrt{n}$*, where* $d(n)$ *is the number of divisors of* n*; the series and the product converge absolutely and agree for* $\operatorname{Re} s > 3/2$*.*

(ii) $a_{mn} = a_m a_n$ *for coprime* m, n*;* $a_{p^{k+1}} = a_p a_{p^k} - p a_{p^{k-1}}$ *for* $p \nmid N$*,* $k \geq 1$*; and* $a_{p^k} = a_p^k$ *for* $p \mid N$*.*

(iii) For $p \neq \ell$ *the local factor is* $L_p(V_\ell E^\vee, s) = \det(1 - \mathrm{Frob}_p^{-1} p^{-s} \mid (V_\ell E^\vee)^{I_p})^{-1}$ *(Convention 9.40): at good* p *by Theorem 9.67; at bad* p*, where* $\dim (V_\ell E^\vee)^{I_p}$ *is* 1 *(multiplicative, with* Frob_p^{-1} *acting by* $a_p = \pm 1$*) or* 0 *(additive), by Chapter 11. At a good prime this is also* $\det(1 - \mathrm{Frob}_p\, p^{-s} \mid V_\ell E)^{-1}$*, but not at a multiplicative prime: there the arithmetic Frobenius acts on the line* $(V_\ell E)^{I_p}$ *by* $p a_p$*, not by* a_p*. Isogenous curves have the same* L*-function (Theorem 9.74(ii) and the invariance of the conductor), and* $L(E^{(d)}, s)$ *has the same local factors as* $\sum \chi_d(n) a_n n^{-s}$ *at the primes* $p \nmid ND$ *(Corollary 9.87).*

(iv) (Modularity.) $L(E,s) = L(f_E, s)$ *for a newform* f_E *of weight* 2 *on* $\Gamma_0(N)$*;* $L(E,s)$ *extends to an entire function and satisfies a functional equation under* $s \mapsto 2 - s$*.*

Proof. (i) At a good prime, $(1 - a_p X + pX^2)^{-1} = \big((1-\alpha_p X)(1-\beta_p X)\big)^{-1}$, so $a_{p^k} = \sum_{i=0}^{k} \alpha_p^i \beta_p^{k-i}$ and $|a_{p^k}| \leq (k+1)p^{k/2}$ by Theorem 9.63(iii); at a bad prime $|a_{p^k}| = |a_p|^k \leq 1$. With (ii) this gives $|a_n| \leq d(n)\sqrt{n}$. Since $d(n) = O(n^c)$ for every $c > 0$, $\sum |a_n| n^{-\sigma}$ converges for $\sigma > 3/2$; the product of the absolutely convergent local series over $p \leq x$ contains every $a_n n^{-s}$ with all prime factors of n at most x, and the difference from the full series tends to 0. (ii) Expanding the product, a_n is the product of the coefficients a_{p^k} of the local series for $p^k \parallel n$; the recursion is the coefficient of X^{k+1} in $(1 - a_p X + pX^2) \sum_k a_{p^k} X^k = 1$. (iii) At a good prime $\det(1 - \mathrm{Frob}_p^{-1} X \mid V_\ell E^\vee) = \det(1 - \mathrm{Frob}_p X \mid V_\ell E) = 1 - a_p X + pX^2$ by Convention 9.40 and Theorem 9.67; the bad primes are Chapter 11. At a multiplicative prime $V_\ell E$ restricted to the decomposition group is an extension of ε by $\varepsilon\chi_\ell$, with ε unramified and $\varepsilon(\mathrm{Frob}_p) = a_p$ (Chapter 10), so the inertia invariants of $V_\ell E$ are the line $\varepsilon\chi_\ell$, with arithmetic Frobenius eigenvalue $p a_p$, and those of $V_\ell E^\vee \simeq V_\ell E \otimes \chi_\ell^{-1}$ are the line ε, with geometric Frobenius eigenvalue $\varepsilon(\mathrm{Frob}_p)^{-1} = a_p$. (iv) We do not prove this; it is the theorem of Wiles, Taylor-Wiles and Breuil, Conrad, Diamond and Taylor [207, 197, 16], with the analytic statements from the theory of modular forms; see Chapters 14 and 19. □

For `11a1`, $a_1, \ldots, a_{13} = 1, -2, -1, 2, 1, 2, -2, 0, -2, -2, 1, -2, 4$; for instance $a_4 = a_2^2 - 2 = 2$, $a_8 = a_2 a_4 - 2a_2 = 0$, $a_9 = a_3^2 - 3 = -2$, and $a_{11} = 1$ (11 is split multiplicative). The composite indices come from multiplicativity: $a_6 = a_2 a_3 = 2$, $a_{10} = a_2 a_5 = -2$, $a_{12} = a_4 a_3 = -2$. The local factor at 2 is $(1 + 2\cdot 2^{-s} + 2^{1-2s})^{-1} = \sum_k a_{2^k} 2^{-ks}$, and the recursion $a_{2^{k+1}} = -2a_{2^k} - 2a_{2^{k-1}}$ continues $1, -2, 2, 0, -4, 8, -8, 0, \ldots$; the bound of (i) reads $|a_{2^k}| \leq (k+1)2^{k/2}$, here $|a_{16}| = 4 \leq 5 \cdot 4$.

9.12 Labels and the running examples

The paper names curves by Cremona's labels and relies on Cremona's convention that the first curve of a class is the optimal one. This section explains the labels, gives their LMFDB equivalents, and collects in one table the data of the curves that the paper and this book use as running examples. The modular degrees, Kodaira types and images are proved or computed in Chapters 10, 11 and 14; here they are quoted from Cremona's files [36] and checked with PARI.

Convention 9.95 (Cremona and LMFDB labels)**.**
